Apparatus for treating water with purifying reagents such as those for flocculation. Samuel B. Applebaum (to Permutit Co.). U. S. 2,179,246, Nov. 7. Water-treating app. for continuous flocculation comprises a settling chamber, a cylindrical upright member, liquid inlet and outlet means at opposite ends of the member directing a vertical flow therethrough of liquid carrying impurities to be flocculated, the outlet means communicating with the settling chamber, means for adding a reagent to the liquid entering through the inlet means, high speed agitator means adjacent the inlet end of the member for imparting speedy horizontal rotary motion to the flowing liquid with agitation and homogenization thereof, relatively slow-motion horizontal rotary agitator means in a succeeding relation to the high-speed means, two vertical shafts for driving the agitator means and means for respectively rotating the shafts at different speeds and mounted above the member.

Apparatus for gentle agitation of liquids, as in chemical treatments of water, etc. Eric Pick (to Permutit Co.). U. S. 2,179,271, Nov. 7. Various structural, mech. and operative details.

Cation-exchanging products from lignite or peat. Walther Sütterlin and Hans Wassenegger (to I. G. Farbenind. A.-G.). U. S. 2,172,301, Sept. 5. The cation-

exchanging properties of lignite or peat are improved by heating with an alkali metal sulfite or bisulfite or an alk. earth metal bisulfite, in the presence of water, to a temp. between 100° and about 200°, under nonalk. conditions, and with CH_2O or AcH. Several examples with details of procedure are given.

Sewage treatment. John G. Bevan (to Guggenheim Bros.). U. S. 2,177,857, Oct. 31. An arrangement of app. is described, and a treatment of sewage contg. putrescible matter which involves subjecting the sewage to the action of a water-sol. compd. of a trivalent metal, such as $Fe_2(SO_4)_3$, to coagulate the putrescible matter, sepg. the coagulated matter as a sludge, subjecting the sludge, without drying, to the action of an acid such as H_2SO_4 capable of regenerating (and in an amount not substantially in excess of that required to regenerate) the sol. metal compd., maintaining oxidizing conditions within the body of the acid-treated sludge and utilizing the acid-treated sludge in conjunction with added trivalent metal compd. for the treatment of addnl. sewage to coagulate putrescible matter in it.

Digester (with superposed chambers) for conversion of organic wastes such as garbage, etc., by bacterial action. Geo. H. Earp-Thomas. U. S. 2,178,818, Nov. 7; Can. 385,163, Nov. 21, 1939. Various structural, mech. and operative details.

15—SOILS, FERTILIZERS AND AGRICULTURAL POISONS

M. S. ANDERSON AND K. D. JACOB

Classification of clay and sand-carbonate soils. N. V. Frolova. *Soviet Geol.* 9, No. 7, 62–70(1939). F. H. R.

Summary of recent investigations on Brazilian soils. A. Barreto. *Soil Sci.* 48, 317–21(1939).—It is difficult to predict the fertility of lateritic soils on the basis of ordinary types of lab. study. Titration with alc. NaOH gives results which are helpful. The method is as follows: Vigorously shake 5 g. of air-dried soil with 50 to 100 cc. of 4 alc. 0.1 *N* NaOH. After settling 5 to 10 min. an aliquot of the supernatant soln. is drawn off for titration with 0.1 *N* HCl, bromothymol blue being used as indicator. The result, expressed as cc. of NaOH neutralized per 100 g. soil, is designated as the "alcoxic index." The more fertile soils give indexes ranging from 400 to 800. A soil from Estrado da Bahia, Brazil, had an "alcoxic index" of 350 for the *A* horizon, 850 for the *B* and 650 for the *C* horizon.

M. S. Anderson

Soil types of Manchukuo. III. Determination of exchangeable lime in calcareous soil. Rokuro Kawasima. *J. Agr. Chem. Soc. Japan* 15, 151–5(1939); cf. *C. A.* 33, 4361⁷.—The exchangeable lime in soils contg. $CaCO_3$ in a pptd. form was detd. Both Hissink's and Chapman and Kelley's (*C. A.* 25, 551) methods were inadequate, while Puri's (*C. A.* 29, 6993⁶) NH_4 carbonate soln. method was suitable. **IV. A saline alkali soil.** Rokuro Kawasima and Masanao Nagata. *Ibid.* 809–14.—The surface soil of a saline alkali soil contained a lower concn. of sol. salts but a higher amt. of bivalent cations. pH of the surface soil was 8.36–8.75, while that of the subsoil was 9.19–9.37. The H_2O-sol. salts consisted of 90% of Na salt. The soil can be reclaimed by adequate draining. **V. Acid mineral soil in South Manchuria.** Rokuro Kawasima. *Ibid.* 815–18.—An acid mineral soil of low lime satn. was widely distributed along the coast of South Manchuria. The 7 acidity of the surface soil was generally weaker than that of the subsoil owing to the herbaceous covering. **VI. Steppe soil between Harbin and Tsissikhar.** *Ibid.* 947–52.—A steppe soil contained 95.2% of exchangeable Ca and had pH (H_2O) 8.08–8.29. The silica-sesquioxide ratio and silica-alumina ratio in the colloidal clay were, resp., 2.74 and 3.6.

Y. Kihara

A study of two granite soils developed under tropical and temperate weathering conditions. Edward Crompton. *Mem. Proc. Manchester Lit. and Phil. Soc.* 83, 117–27(1938–39).—The effects of different weathering conditions on the development of 2 soil profiles formed from granite are compared. The Malacca sample came 8 from a location where the atm. humidity is tremendously high, pptn. occurs as torrential downpours and the climate is equable with temps. varying only a degree or 2 from 87°F. At Shap, source of the second sample, pptn. occurs 9 as moderately light cyclonic rain with some snow in the winter and the av. winter temps. are very little above freezing and in the summer the hottest month only 55°F. The Malacca soil is a slightly lateritic red earth and the Shap soil is a shallow, immature heath podzol. Mech. analysis shows no very great variation throughout the Malacca profile with the clay fraction running about 30–40% in the first 10 ft. The surface soil is the most acidic. There is much greater variation in the percentages of the several fractions in the Shap profile. The org. matter content is much higher in the Shap soil and there is generally a considerable accumulation of humus in the form of a peaty layer just below the surface. At Shap the soil changes to hard parent rock at a depth of 1 ft. 7 in. while the Malacca soil changes to disintegrating rock at a depth of 12 ft. The uniformity of percentages in the mech. analyses of the Malacca soil is also found in the chem. analyses. The Shap soil, on the contrary, gives greater variations in chem. compn. The ferrosilicate minerals in these soils are more abundant in the fine sand than in the coarse sand. The mech., chem. and mineralogical analyses are tabulated.

J. R. Adams

Forest soil studies. I. Relation of rate of decomposition of tree leaves to their acid-base balance and other chemical properties. W. M. Broadfoot and W. H. Pierre. *Soil Sci.* 48, 329–48(1939).—Mature, undecompd. leaves and needles representing 19 species of forest trees were studied with respect to differences in chem. properties, and rates of decompn. The pH values of the different samples varied from 3.46 to 6.68, with most of the values below 5.0. The N contents varied between 0.5% for leaves from the sugar maple and 2.06 for 6 those of the black locust. The ash contents varied from 1.94 for material from pitch pine to 11.54 for a sample from black walnut. Ca varied from 19.1 milliequiv./100 g. for scrub pine to 162.8 for dogwood. The excess-base content of the different samples varied from 38.2 milliequiv./100 g. for a sample of pitch pine to 214.7 for black walnut. Some variation exists in the chem. compn. of different samples from the same tree species. Greater differences, however, are found between the different species and genera with respect to N, Ca, ash and excess base. In general, the pH of residual material increased progressively as decompn. proceeded. There was no definite relationship between the pH of the original material and the pH of the residual org. matter. Leaves high in excess base generally gave, upon decompn., a residue of high pH value, while those of low excess base gave a low pH value. After a 6-month period, decompn. averaged less than 25% for samples of pitch pine, scrub pine, white pine, beech and sycamore, whereas it averaged over 45% for samples of yellow poplar, staghorn sumac, black locust and black walnut. Properties closely assocd. with rate of decompn. are H_2O-sol. org. matter content and excess-base content. The multiple coeff. of correlation between percentage decompn. during a 6-month period and these 3 variables was 0.862.

M. S. Anderson

The acidic properties of peat and muck. Irvin C. Feustel. *U. S. Dept. Agr., Tech. Bull.* 690, 41 pp.(1939). —Typical samples of peat and muck were divided into 3 fractions, viz.: the material dissolved by alkali and subsequently pptd. by acid, material dispersed to colloidal dimensions and the remaining residue. These were termed humic acid, colloid and residue, resp. C-N ratios indicated significant differences in the character of the org. materials present in the different peats and in the different fractions. The residue fractions had exceptionally high

ratios while that of the colloid and humic acid fractions was relatively low. The humic acid fraction generally accounted for the major portion of the total acidity possessed by each sample of peat or muck. Base-exchange capacities detd. by leaching with a neutral normal soln. of $Ba(C_2H_3O_3)_2$ were materially less than the base-neutralizing capacities detd. by titration. The arbitrary values for NH_3 absorbed and retained on drying 5 hrs. at 105° were of lesser magnitude than the base-exchange capacities. Each set of detns. demonstrated significant differences among the different types of materials. The results obtained indicate that the NH_3-retaining and base-exchange capacity detns. each measure different and variable fractions of the total acidic H present in the peat and muck materials. W. H. Ross

Agronomic and horticultural considerations in the use of simple chemical soil tests. M. F. Morgan. *Am. Fertilizer*, **91**, No. 10, 5–6, 24, 26(1939).—The characteristics of the various rapid chem. tests that are most commonly used in various sections of the country are described. These soil tests can serve as a useful guide toward a more intelligent use of fertilizers and other soil-improving practices, but only as they are applied in relation to results obtained on many soils of known soil management and crop production and of phys. soil type similar to the particular soil in question. W. H. Ross

Determination and distribution of boron in soils. W. O. Robinson, R. R. Whetstone and H. G. Byers. *Am. Fertilizer* **91**, No. 11, 7–9, 24, 26(1939).—A H_3PO_4 digestion method is described for detg. sol. B in soils and a fusion method, with Na_2HPO_4 and H_3PO_4 as a flux, for detg. total B. Results are given of the analysis for the B content of a no. of soil profile samples. Peat, coastal plain and podzol soils are the lowest in acid-sol. B, while chernozem and Sharkey clay soils are the highest. The total B is highest in the Hagerstown soils. In the Sharkey soil practically all the total B is acid-sol. whereas in the Hagerstown soil not more than 10% of the total B is acid-sol. W. H. Ross

An indirect method for determining the moisture content of soils at the sticky point. Feng Chao-Lin. *Soil Sci.* 48, 323–8(1939); cf. *C. A.* **31**, 5915⁷.—A "sticky point" method is described based upon the fact that when drops of water are slowly added to a plain surface of fine soil a nearly hemispherical mass is formed, which, if picked up and kneaded by hand, just reaches the stage at which it no longer sticks to the hands or blade of the knife. The method is rapid and is applicable to all kinds of soil except those contg. large quantities of sol. salts. M. S. A.

Methods for estimating the corrosivity of soils. K. H. Logan and E. A. Koenig. *Gas* **16**, No. 1, 19–22(1940).—Eight methods were used to evaluate the corrosiveness of soils: (1) soil resistivity (Shepard resistivity meter); (2) soil resistivity at moisture equiv.; (3) soil acidity; (4) acidity-resistivity test; (5) the Columbia rod test; (6) the Putnam test; (7) the nipple-and-can test; and (8) the Denison electrolytic test. Av. results for these tests were plotted against pit depths. The resulting graph did not show a great deal of difference in the degree of correlation of the results of most of the tests with pit depths. All methods show in a very general way the corrosiveness of the soil samples, but whenever several test results having the same value were obtained, widely divergent pit depths are assocd. with them. There appears to be no fixed relation between the results of the tests and the max. pit on the joint of the pipe nearest the sample tested. R. W. Ryan

The adsorbed ions of colloidal clay as a factor in nitrogen fixation by Azotobacter. T. M. McCalla. *Soil Sci.* **48**, 281–6(1939); cf. *C. A.* **32**, 7180⁸.—Colloidal clay served successfully as a basic medium for the fixation of atm. N by *Azotobacter* when added to a nutrient soln. In a comparison of different supplements to Ashby's medium norite gave no fixation of N, permutite very slight fixation and bentonite and zeolite were very effective. A colloidal clay was electrodialyzed. Nutrients such as Ca, K and P were added in const. amts., but with varying amts. of Sr or Ba and reciprocal amts. of Mg. The media were then sterilized, inoculated with *Azotobacter* and aerated for 3 days, by forcing air through the suspension. The best fixation of atm. N occurred with a high level of Mg in the case of the Ba and Mg series. Variable amts. of Mg and Sr gave approx. const. N fixation. Fixation was good in the presence of H-clay. Suspended inert solid material did not serve as effectively in promoting N fixation as did a colloidal material with a base-exchange capacity. M. S. Anderson

Calcium deficiency. T. R. Swanback. *Conn. Agr. Expt. Sta.* (New Haven), *Bull.* 422, 16–18(1939); *Tobacco Substa. Windsor, Rept.* 1938.—Although the soil pH was not less than 5.0, a neg. test was often found for replaceable Ca in Conn. tobacco soils. The deficiency results in leaf and bud injury. Excessive rains produced considerable Ca deficiency (previously unobserved) in Conn. Suggested remedy is the addn. of not more than 500 lb. of Ca per acre in order to supply Ca and yet not fix the minor elements. In addn., $CaSO_4$ at the rate of 500 lb. per acre may be applied. C. R. Fellers

Nitrogen fertilization of grassland. IV. Report of 12 cutting seasons. H. J. Frankena and M. P. Both. *Verslag. Landb. Onderzoek.* No. 45, A (10), 255–97(1939) (summary in German, 296–7); cf. *C. A.* **31**, 3614⁴.—Expts. were conducted during 1936, '37 and '38. As N fertilizer Ca NH_4 saltpeter was applied in spring in progressive amts. and sufficient P and K all on different soils. The yield on clay soils shows a max. in early June, sandy soils the same, but clay-humus soils a little later. Results were greatly influenced by weather conditions, the least on clay soils. With only 1 application of N fertilizer in spring, the aftereffect on the second cut is small, and this decrease is smaller in proportion to the increase of yield of the first cut. It is desirable to distribute the N application over 2 cuts. Early-cut hay has greater nutrition value than later cuts; albumin and starch both decrease. As yield increases albumin decreases. Only with a very early cutting time the albumin is increased a little by N fertilization, but at later periods it has no effect. The N absorption is greatly influenced by the type of soil; it is greatest in clay soils and lowest in humus soils. N fertilization does not have much effect on the botanical compn. All results are extensively tabulated. **V. Report of 4 treated experimental plots.** H. J. Frankena. *Ibid.* (11), 299–334 (summary in German, 333–4).—It is recommended to alternate the grazing and cutting periods; thus, grazing in early May, then applying 40–60 kg. N/ha. and cutting at the end of June. The daily growth is not the same for the different cutting periods; during the first months there is a large increase in daily dry matter decreasing in summer. The chem. compn. of the grass is primarily a function of the period of growth. Rapid growth produces high value; N fertilization increases the albumin content in young grass as well as the difference between crude and pure albumin. The botanical compn. of the grasses as per dry matter analysis is quite different for the seasons: more weeds in spring, more clover in summer and more meadow-grass in fall. **VI. Crop yield of seven experimental plots with nitrogen fertilization during spring.** H. J. Frankena and M. P. Both. *Ibid.* (12), 335–60(summary in German, 359–60).—In 1937 increasing amts. of Ca NH_4 saltpeter were applied on the 3rd, 18th and 31st of March and the 12th of April, and in 1938 on Feb. 21st, March 9th and 30th and April 10th. The first cuts for 1937 were on May 3rd, 13th and 25th and June 3rd, and the second cuts May 3rd and June 9th. For 1938 the first cuts were May 12th and 24th and June 9th, the second cuts May 13th and June 9th. The highest yield for 1937 was from plots fertilized on March 31st. In 1938 the N fertilizer applied on March 9th gave best results on all cuts. For the June 9th cut the fertilization of March 30th gave the best results. Weather conditions greatly affect the action of N fertilization. Although the N applied earlier in the season did not change the N content of the grass to a great extent, N content was decidedly higher after the last N application than that of the plots without N fertilization, especially during the earliest cutting periods. J. C. Jurrjens

Phosphorus in Wyoming pasture, hay and other feeds.

O. C. McCreary. *Wyo. Agr. Expt. Sta., Bull.* **233**, 20 pp. (1939).—Wyo. soils are often deficient in P. The P in the dry matter of plants is relatively high in those which grow rapidly. Since plants grow rapidly only when a sufficient amt. of moisture is present, there is a close relationship between the percentage of P in pasture grasses and rainfall. Grasses, sedges and rushes have similar P contents if collected at the same stages of growth and if grown on soils of similar moisture content. The Ca-P ratio of Wyo. grasses varies from 2:1 to 6:1. The grains such as corn, oats, barley and wheat are low in Ca and relatively high in P. C. R. Fellers

Phosphates and their utilization. F. S. Lodge. *Am. Fertilizer* **91**, No. 9, 9–11, 26(1939).—A review. W. H. Ross

Effect of boron supply on growing tobacco. Giuseppe Leone. *Boll. tec. ist. sper. colt. tabacchi "Leonardo Angeloni" Scafati*, **36**, 149–53(1939).—B was added to soil plots in Salerno, Italy, at the rate of 9 kg. of $Na_2B_4O_7$ per acre. Turkish tobacco of the type, Xanti-Yaka, grown on the B-treated plots contained less nicotine than controls. Cigarets made from the processed tobacco of each kind were of better quality in the B-fertilized tobacco. The characteristics and analyses of the soil and the smoking properties of the tobaccos are included in the discussion. N. T. Farinacci

Effect of ammonium and nitrate nitrogen on the mineral composition and sap characteristics of barley. D. I. Arnon. *Soil Sci.* **48**, 295–307(1939); cf. *C. A.* **31**, 8098[2].—Detn. of Ca, Mg, K, N and P, as well as of pH, cond. and total sugars of the expressed sap were made on 5-week-old barley plants grown in nutrient solns. supplied with either NH_4 or nitrate as a sole source of N. The plants were grown at different seasons with control of variables such as pH, aeration and concn. of Mn. The plants utilizing NH_4 had higher P and lower Ca, Mg and K contents than the plants grown with nitrate. Shoots grown in NH_4 solns. at pH 5 had a total cation content of 576 milliequivs. per 100 g. of dry tissue, and 48 8 milliequivs. of anions. In the nitrate soln. the shoots had 331 milliequivs. of cations and 439 of anions. In the first case all N was calcd. as cations and in the latter all N as anions. Variations in pH of the culture soln. had but little influence on the plant compn. Varying the pH of the nutrient soln. between the range 4.0 and 6.7 had little influence on the pH of the expressed sap. The sap of shoots of NH_4-grown plants had a consistently high sugar concn. and lower cond. than the nitrate-grown plants. The sap of roots had in each case lower cond. than that of the shoots. Nitrate-grown plants had a greater adsorptive power for Mn than did the NH_4-grown ones. M. S. Anderson

Influences of potassium upon the contents of sugar and starch in the stems and leaves of paddy rice. Tatuo Koyanagi. *J. Agr. Chem. Soc. Japan* **15**, 757–67; *Bull. Agr. Chem. Soc. Japan* **15**, 119–22(1939)(in German).—When excess of K as fertilizer was added, the yield of paddy rice decreased. With increase in quantity of K, the contents of sugar and N decreased while that of starch increased at the former stage. At the latter stage the contents of sugar and starch increased with the quantity of K. The relation of the sugar content was greatly affected by the amt. of N fertilizer. The quantities of ash and K_2O in the stems and leaves increased with the amt. of K fertilizer added. Y. Kihara

Absorption of iron from finely ground magnetite by citrus seedlings. H. D. Chapman. *Soil Sci.* **48**, 309–15 (1939).—Magnetite was ground to particle sizes of approx. 1 μ diam. An undetectable quantity of Fe was dissolved from 0.1 g. of magnetite in 100 cc. of soln. in the presence of 2.5 g. $CaCO_3$ when CO_2-free air was passed through. When CO_2 gas was passed through, a small but detectable quantity of iron was dissolved. When $CaCO_3$ was omitted from the suspension, and CO_2 passed through, 0.5 p. p. m. of Fe was found in the soln. Ground magnetite as a source of Fe in sand cultures for citrus seedlings is made possible by the formation of intimate contacts between roots and Fe_3O_4 particles. Under these conditions extn. or soln. of Fe is different from those prevailing in the nutrient soln. external to the particles. It is probable that the no. as well as the intimacy and character of contacts is important in detg. nutrient adequacy or inadequacy. M. S. A.

The use of soil conductivity bridge for determining injury to transplanted tomatoes from improper fertilization. Jackson B. Hester. *Am. Fertilizer* **91**, No. 9, 5–8 (1939).—Data showing the use of the cond. bridge in detecting injury from improper fertilization are given. Plants set in soil that has a resistance of approx. 300 ohms are likely to be injured from excessive salt concn. The injury can be eliminated or minimized by any one of several methods, such as, (*a*) adopting proper method of band placement; (*b*) putting the phosphate down with some N and sidedressing with N and K_2O; (*c*) placing a small amt. of the fertilizer underneath the plant and sidedressing later; and (*d*) broadcasting and mixing with the soil before planting. W. H. Ross

Use of calcium cyanamide. Alexander Gordon. *Sugar News* **20**, 513–16(1939).—There is little choice between $CaCN_2$ and $(NH_4)_2SO_4$ as a source of N for sugar-cane cultivation. Cumulative effect on clayey soils and juice qualities are better where $CaCN_2$ is used. W. W. B.

Statistical investigations on sugar-beet yields (and soils). J. R. Bruinsma. *Mededeel. Inst. Suikerbietenteelt* **9**, 373–95(1939).—Data from 105 com. fields show close correlation between $CaCO_3$ in the soil and sugar percentage content of the beets; the relation is asymptotic and reaches a max. with about 1.6% of soil $CaCO_3$. O. W. Willcox

Agrobiology applied to the sugar beet. Guido Bellardini. *Ind. saccar. ital.* **32**, 539–45, 574–86, 601–11(1939).—Applications of agrobiological principles in the quant. coordination of abs. units of growth factors (fertilizers) with abs. units of quantity of plant life (yielding ability) are summarized. Breeding and selecting operations for obtaining new varieties with larger yields should be guided by the inverse yield/nitrogen law. O. W. W.

Criteria for the evaluation of agricultural ground limestone. R. M. Salter and C. J. Schollenberger. *Am. Soc. Testing Materials, Symposium on Lime* **1939**, 71–82 (1940).—Sieve analyses of numerous samples of agricultural ground limestone indicate the advisability of classification into the grades superfine, pulverized, standard agricultural ground, meal and screenings, with approx. 100, 93, 72, 46 and 28%, resp., passing a 48-mesh sieve, the median size used in testing. A plot of cumulative percentage through Tyler sieves *vs.* logs mesh diams. is in each case a concave curve, but all are practically straight lines of uniform slope if only the finer and more valuable fractions are considered. Calcns. of relative value based on the complete sieve analysis (cf. Bear and Allen, *C. A.* **26**, 5799) and on the straight line size compn. noted give nearly identical results, indicating that graphic computation from a chart with few sieve data should be sufficiently accurate for practical purposes. Tests with 48–65 mesh separates from representative stones varying from nearly pure $CaCO_3$ to $CaMg(CO_3)_2$, incorporated in soil and decompn. of carbonate noted after different periods of exposure to natural conditions, indicate that for short periods the rate of decompn. varies approx. inversely with the dolomite content and is independent of earthy impurities except as the latter dil. the stone; the relation is formulated. Data are cited, showing that the evaluation of limestone according to these methods is in accord with results observed in long-continued field trials with materials of known size compn. Twenty-two references. C. J. Schollenberger

Losses of fertilizer constituents by leaching during an abnormally wet growing season. M. F. Morgan and O. E. Street. *Conn. Agr. Expt. Sta.* (New Haven), *Bull.* **422**, 6–16(1939); *Tobacco Substa. Windsor, Rept.* **1938**; cf. *C. A.* **30**, 8472[3]; **29**, 7395[4].—Losses from a normally fertilized sandy soil during the 1938 growing season were approx.: N 100–150 lb. per acre, K_2O 50–75, CaO 140–160 and MgO 30–40. The leaching losses were usually in inverse proportion to the wt. of the crop on the 30-in. lysimeters. It is certain that extensive rainfall removes vast quantities of plant nutrients from Conn. soils. C. R. Fellers

Effects of fertilizers, especially of potassium, on sweet potatoes as the source of alcohol. I. Akira Suzuki, Sinzi Doi, Teiziro Uemura, Yintyang Wang, Seizi Tada and Rikizo Takahasi. *J. Agr. Chem. Soc. Japan* **15**, 989–1005(1939).—When sweet potatoes were cultivated with complete fertilizer, the yield was unusually high. Lack of P gave a noticeable decrease in yield. Sweet potatoes cultivated with a complete fertilizer had high starch and dextrin contents, but a low sugar content. When incomplete fertilizer was used, the hydrolysis in the digestion was small, starch was more easily hydrolyzable and the fermentation ratio was higher. Y. Kihara 1 2

Apparent discrepancies in the amount of magnesia in phosphatic fertilizers as determined by various methods. W. Catesby Jones. *Am. Fertilizer* **91**, No. 7, 5–6(1939).—Results are given for the MgO content of 7 mixed fertilizer samples as detd. by 8 methods of analysis. The Bartlett-Tobey method using the acidimetric titration suggested by Shuey is considered to be an ideal method for detg. MgO in fertilizers, particularly when P_2O_5 and CaO are to be detd. in the same sample. The 3 detns. can be made from the same soln., thus necessitating only one weighing of the sample. W. H. Ross 3

Fertilizers, 1940. Charles J. Brand. *Mfrs. Record* **109**, No. 1, 41, 60(1940).—Descriptive. Leopold Scheflan

Some European impressions relating to fertilizers. C. H. Kunsman. *Am. Fertilizer* **91**, No. 10, 7–8, 22, 24 (1939).—A discourse. W. H. Ross 4

The value of treated town-refuse as an organic manure. E. H. Tripp. *Chemistry & Industry* **1939**, 1102–4.—See *C. A.* **34**, 8441. E. H.

The nitrification of ammonium thiocyanate (a weed eradicant) and the effect of this compound upon the soil population. Allan G. Sandhoff and C. E. Skinner. *Soil Sci.* **48**, 287–94(1939).—Addns. of NH_4CNS and NaCNS to soil were studied in relation to their use as weed eradicants. Their influence was studied by nitrate production and NH_3 content. When 1.25% NH_4CNS was added to unlimed garden soil, there was no change in algae or protozoa content. Bacterial nos. were not changed in 7 weeks, but were reduced in 9 weeks. With addns. of 0.075% NH_4CNS or NaCNS to limed soil, there was always a significant increase in bacterial nos. Bacteria grew vigorously on media, the only N source of which was NaCNS. The application of NH_4CNS in amts. used in the practice of weed eradication forms quickly available N to the extent of only 1/2 of the N in the compd. M. S. Anderson 5

Field experiments in the control of the apple maggot, 1938. Philip Garman. *Conn. Agr. Expt. Sta.* (New Haven), *Bull.* **428**, 72–3(1939).—During seasons of heavy rainfall rotenone is much less effective in apple maggot control. High temps. and humidities destroy rotenone films rapidly and the flies can continue their egg-laying in spite of application at 10-day intervals. C. R. Fellers 6 7

Biology and combating of the apple and pear sawfly (Hoplocampa testudinea Klg., Hoplocampa brevis, Klg.). Helmut Velbinger. *Gartenbauwiss.* **13**, 492–566(1939).—A strong spraying of trees with a quassia-contg. soln. in combination with As, Cu and lime, 3–6 days after fall of blooms, gives good results. The treatment with sprays contg. nicotine, S, lime, $PbAsO_3$, cresol combinations has hardly any effect against the insects. C. K. Horner 8

Control of the oriental fruit moth in peaches and quinces. Philip Garman. *Conn. Agr. Expt. Sta.* (New Haven), *Bull.* **428**, 77–9(1939).—Field tests showed slightly less reduction in injury with bentonite-nicotine spray as compared with talc-oil-S dust. Even though the trees were well covered with the spray and dust, the reduction in total injury was only 15%. Pb arsenate and lime-S spray gave fairly good control of quince insects. A sticker was advantageous. Derris seemed to be of some value in controlling the oriental fruit moth on quinces. C. R. F. 9

Control of damping-off and bedrot by vapors of benzene and *p*-dichlorobenzene. P. J. Anderson. *Conn. Agr. Expt. Sta.* (New Haven), *Bull.* **422**, 39–40(1939); *Tobacco Substa. Windsor, Rept.* **1938**.—The damping-off of seedling tobacco plants is usually caused by the fungus, *Pythium debaryanum*. This disease was controlled by placing sufficient *p*-dichlorobenzene in shallow pans so that 7 g. will be vaporized per sq. yd. of seed bed. The fumes of benzene were also effective against both damping-off and downy mildew of tobacco. C. R. Fellers 1

Further trials with soybean-oil meal. T. R. Swanback. *Conn. Agr. Expt. Sta.* (New Haven), *Bull.* **422**, 19–20 (1939); *Tobacco Substa. Windsor, Rept.* **1938**; cf. *C. A.* **32**, 7194[4].—This material possesses certain advantages over cottonseed meal which was formerly extensively used for tobacco fertilization. The fiber content of soybean-oil meal is only 5.9% as against 10.8% for cottonseed meal. Ammonification is much slower in the soils contg. cottonseed meal. A 3-year summary shows a 13% crop value increase resulting from the use of soybean oil meal in place of the cottonseed meal on tobacco crops. C. R. Fellers 2

Fungistatic properties of the fatty acids and possible biochemical significance. Charles Hoffman, T. Robert Schweitzer and Gaston Dalby. *Food Research* **4**, 539–45 (1939).—The normal satd. fatty acids contg. 1–14 C atoms were studied over a pH range of 2.0–8.0. Capric acid is of especial value because it possesses marked fungistatic properties over a wide pH range. The effectiveness varies according to the chain length, the concn. of the acid, and the pH of the media. A branched-chain acid is usually less effective against molds than the corresponding straight-chain acid. Unsatn. tends to increase the fungistatic effectiveness of an acid. At neutrality, the acids contg. 8–12 C atoms are the most effective. At pH 2.0–3.0 formic acid is slightly more active than AcOH, but above pH 3.0 the latter is more effective. It is possible that the fungistatic properties of a fatty acid may be indicative of anticarcinogenetic properties. C. R. F. 3

Tests of apple sprays. M. P. Zappe and E. M. Stoddard. *Conn. Agr. Expt. Sta.* (New Haven), *Bull.* **428**, 68–71(1939); cf. *C. A.* **32**, 1038[4], 7198[5].—Cu sprays were not so good as S for scab control and had the added disadvantage of russeting the fruit, injuring foliage and decreasing the killing power of the Pb arsenate. Leaf injury was not serious except where Cu oxychloride was used. Curculio injury was best controlled by lime-S and Pb arsenate and least by Cu sprays. Of the several Cu sprays tested Coposil was most promising. C. R. F. 4 5 6

Chemistry and preparation of insect sprays containing pyrethrum. A. F. Caldwell. *J. Malaya Branch Brit. Med. Assoc.* **1**, No. 4, 336–41(1938); *U. S. Pub. Health Eng. Abstracts* **19**, Ma, 28(Sept. 2, 1939).—Watery pyrethrum sprays are preferred for airplane fumigation because there is no fire hazard. Unless the pyrethrum contains at least 0.5% pyrethrins, it is of little insecticidal value. A prepn. of low fire risk is manufd. by cold percolation with kerosene followed by diln. to contain 0.075% pyrethrins. CCl_4 may be substituted for 1/2 of the kerosene further to reduce the danger of fire, providing high-pressure spray app. is available. C. R. Fellers 7

Use of karaya gum as an activator for nicotine sulfate against Aphis rumicis. Philip Garman. *Conn. Agr. Expt. Sta.* (New Haven), *Bull.* **428**, 76(1939).—This gum when used as an activator for nicotine sulfate against aphids under lab. conditions showed no increased toxicity. To 1000 cc. of water were added 0.2 g. nicotine sulfate and 1 g. of karaya gum. When a wetting agent such as Na oleate was used in addn. to the gum, the toxicity was increased by 8–27%. C. R. Fellers 8

Continued experiments with stickers. Philip Garman and C. E. Shepard. *Conn. Agr. Expt. Sta.* (New Haven), *Bull.* **428**, 74–5(1939).—Lab. tests conducted with glass plates and a no. of different adhesives for sprays gave very inconclusive results. Of several soaps, including potash fish-oil soap, NH_4 oleate and triethanolamine oleate, none improved the adhesion of the sprays. The use of adhesives under field conditions with Baldwin apples resulted in some improvement in apple maggot control. C. R. Fellers 9

Studies on oxyuriasis—chemistry of membranes of pinworm egg ovicides (Jacobs, Jones) III. Compn. of alc.

ext. of cane leaves [fertilizer effect on] (Beauchamp, Lazo) **11D.** Process studies of manuf. of $CaCN_2$ (Heilmann) **4.** Beet cultivation (Wintzell) **28.** Aliphatic polyamines [for use in insecticides and fungicides] (U. S. pat. 2,178, 522) **13.** Alkyl hydroxy aromatic compds. [as insecticides, parasiticides or vermicides] (U. S. pat. 2,178,-571) **13.** Org. Hg compds. [fungicides] (U. S. pat. 2,178,099) **17.**

Belgrave, W. N. C.: Annual Report on the Departments of Agriculture, Malaya, for the year 1938. Kuala Lumpur, Federated Malay States. Govt. Press, W. H. Wyatt, Govt. Printer. 91 pp. $1.00 or 2s. 4d.

Fertilizer. Herman B. Siems (to Industrial Patents Corp.). Can. 384,997, Nov. 7, 1939. Calcined phosphate rock is neutralized with HNO_3 in the presence of the fertilizer materials.

Agent for treatment of soil and plants. József Sellei. Hung. 121,474, Sept. 15, 1939. Add to one l. of a slightly alk. aq. soln. not more than 70 g. of a fluorescent dye and less than 40 g. water-sol. copper salt and (or) less than 80 g. water-sol. iron salt (e. g. 100–300 mg. eosin to 100 l. water or to 60 kg. peat). The liquid may be absorbed by peat before application to the soil. Expts. proved that such dyes stimulate the formation of chlorophyll. Cf. *C. A.* **33**, 7951[1].

Preparing peat for use as a fertilizer, etc. Edward H. Sams. U. S. 2,178,051, Oct. 31. A method of treating peat to render it quickly suitable for such uses as the feeding and bedding of animals and fertilizing consists in removing any unwanted coarse growth there may be over the peat bed, breaking up the surface of the bed to expose the top layer of the bed and to produce an aerobic condition, cultivating readily decayable vegetable matter into the peat, producing heat in the bed by allowing the vegetable matter to decay, permitting the mixt. to stand to effect an initial drying thereof, ridging the mixt. until its moisture content is further reduced, and removing peat from the bed to be used as fertilizer.

Horticultural germicides. Ned M. Sleeper (one-third to Alfred L. Barber and one-sixth each to Rex Lake and William T. Gordon). U. S. 2,178,270, Oct. 31. Infections such as fire blight in pear trees are treated by use of a soln. of a metal complex such as a ferric complex of a tannin.

16—THE FERMENTATION INDUSTRIES

FREY

The microbiological cause of the so-called raspberry disease of cider; production of acetaldehyde by the combined action of alcoholic yeast and acetic bacteria. Gustave Guittonneau, Germain Mocquot and Jean Tavernier. *Compt. rend.* 209, 809–11(1939).—The modern method for the prepn of sweet cider favors the occurrence of "raspberry" disease both by slowing up the alc. fermentation and by allowing the diffusion of acetic bacteria from imperfectly disinfected material. Rachel Brown

Gaseous products of cucumber pickle fermentations. M. K. Veldhuis and John L. Etchells. *Food Research* 4, 621–30(1939).—CO_2 was formed during the fermentation of cucumber pickles in brines ranging from 20 to 80% satn. with NaCl. Larger quantities of gases were evolved during fermentations in 40–60% satd. brines than in brines of 20, 30 and 80% satn. H gas was produced in considerable amts. by all the fermentations observed in 60% satd. brines. In general, H production was much more limited than CO_2. Gases formed in the interiors of hollow pickles or "bloaters" had the same compn. as gasses collected at the tops of the fermenting vats, i. e., CO_2 and sometimes H. C. R. Fellers

Determination of small amounts of alcohol in kefir (alcoholic milk beverage). D. B. Iokhel'son. *Lab. Prakt.* (U. S. S. R.) **14**, No. 8, 20–2(1939).—Kefir is a milk beverage contg. 0.25 to 0.6% alc. Its quality is detd. by a definite relation between lactic acid and alc. The detn. is based on the oxidation of the alc. by an excess of $Cr_2O_7^{--}$ in a H_2SO_4 soln. and detn. of the excess Cr_2O_7 by iodometric titration. Dil. 1 ml. of kefir to 50 ml. with water, pour 5 ml. of this soln. into a 15-ml. flask, add 0.3 g. of MgO, shake, close the flask with a glass tube 1.5 cm. in diam., provided with 2 funnel-like enlargements, and terminating in a cylindrical funnel fitted with a ground-glass stopper. Pour 1 ml. of 0.5% soln. of $K_2Cr_2O_7$ and 1 ml. of strong H_2SO_4 into the cylindrical funnel; they are collected in the joint between the 2 enlargements. Place the app. on an asbestos gauze and heat. The alc. (which is distd. off for 3–5 min.) is oxidized by the Cr mixt. to AcOH. No loss of the liquid or of alc. can occur. Distil off 3–4 ml., cool, remove the upper part and rinse it out with 150–200 ml. of water. Acidify the excess $Cr_2O_7^{--}$ with 5 ml. of a 25% H_2SO_4 soln., add 0.2 g. of cryst. KI, shake the soln., let stand for 10 min. (covered with a watch glass) and titrate with a 0.01 *N* $S_2O_3^{--}$ soln. with an addn. of 1 ml. of starch soln. The end point is reached when the blue color changes to light-green. The concn. of the Cr mixt. is detd. by distg. water through it instead of kefir and the amt. of alc. by the difference in the amts. of the 0.01 *N* $S_2O_3^{--}$ soln. used. The proposed method gives better results than the standard OST 7761 method. The av. error was about 0.1%. Five references are given. W. R. Henn

Attempt to estimate glycerol in wines. Vicentina Cunha. *Arquiv. hig. saúde pública* (São Paulo) **4**, No. 6, 65–6(1939).—On decolorizing the wine and treating it with Br, resorcinol and H_2SO_4 a color is obtained which matches perfectly with a similarly treated standard glycerol soln. O. W. Willcox

Effects of fertilizers—on sweet potatoes as source of alc (Suzuki, *et al.*) **15.** Rubber and brewing industry (Griffiths) **30.**

Acetic acid. Anna Brünner. Hung. 121,908, Nov. 2, 1939. A fermentation device equipped with aerating pumps is described.

Malt-like sirups suitable for use in brewing and baking processes. Leo Stein, James F. Walsh and Haskell C. Needle (Walsh and Needle to American-Maize-Products Co.). U. S. 2,179,203, Nov. 7. A method of producing a malt-like sirup from corn steep water and corn sirup involves first substantially neutralizing the steep water to effect pptn. of the heat-coagulable proteins, filtering to remove the pptd. materials, blending the filtered steep water with a corn sirup, concg. the resulting liquid to produce a sirup of the desired consistency and thereafter heating sufficiently to impart to the sirup a characteristic malt aroma and flavor. Various details of procedure are described.

Starch-decomposing substance. István Friedmann. Hung. 122,085, Nov. 15, 1939. Malt is germinated and the green malt of 50–60% water content is treated in an airtight app. at a temp. not exceeding 60–82° for not more than 3 hrs. to obtain a product of 30–50% water content. This is then dried at 30–40° or extd. with water and the soln. evapd. *in vacuo*.

17—PHARMACEUTICALS, COSMETICS AND PERFUMES

W. O. EMERY

Methylcellulose in pharmacy. Gordon A. Bergy. *Am. Professional Pharmacist* **5**, 691–4(1939).—The advantages, properties, prepn. and possible uses in pharmacy especially for the prepn. of pastes, dentifrices, creams, depilatories and hair dressings are discussed. H. M. Burlage

Cosmetic manual. Night creams. Joseph Kalish. 2 *Drug Cosmetic Ind.* **45**, 678–80, 691(1939).—The term "night cream" is used for products known as tissue creams, nourishing creams, skin foods, etc., since the latter names are considered as misleading by the Federal Trade Commission. They have as the active ingredient a vegetable or animal fatty substance which is easily absorbed by the skin and has a softening effect and is used to supply oils and fatty materials lacking in the dry skin. Ingredients 3 and manuf. are discussed. Formulas for beeswax-borax creams of the oil-in-H_2O type (40), cold cream and stearate type (2), those with oil-in-H_2O emulsifiers other than beeswax and borax (6), H_2O-in-oil creams with lanolin (11) and with absorption bases (6) are offered. H. M. Burlage

The tightness of various types of containers for packaging hygroscopic and efflorescent chemicals. John F. Ross and L. Kaplan. *Bull. Natl. Formulary Comm.* **8**, 4 76–87(1939).—$CaCl_2$ U. S. P. XI and Na_2HPO_4 U. S. P. XI were used in the tests and the results indicated that plain cardboard containers and untreated cardboard canisters are not suitable for packaging these types of chemicals. Specially treated cardboard canisters and tin cans appear to be sufficiently impervious to moisture and to meet the usual com. requirements. Glass bottles with screw caps and suitable liners appear to represent the tightest practi- 5 cal com. package and are suitable for storage of the chemicals under av. conditions. No major differences were found between the values obtained with unopened and opened and reclosed packages. Percentage loss varies with the quantity of chemical under test. An attempt was made to eliminate the package size by calcg. the loss in g. per sq. cm. of container surface. H. M. Burlage

The new assay process as applied to fluidextracts of Belladonna leaf, hyoscyamus and stramonium. *Rept. Am. Pharm. Assoc. Lab., Bull. Natl. Formulary Comm.* **8**, 88–93(1939).—As a result of a crit. study of the National Formulary VI methods, revisions for the 3 assays are offered. H. M. Burlage 6

Volatile oil content of Salvia. *Rept. Am. Pharm. Assoc. Lab., Bull. Natl. Formulary Comm.* **8**, 93–6(1939).—Clevinger's method was used. Three samples of official sage yield 1.2, 1.1 and 1.3% volatile oil and the following consts. are reported: d_{25} 0.918, 0.925, 0.925; $[\alpha]_{25}$ (100- 7 mm. tube) 9.2, 6.7, 7.5; n^{20} 1.4616, 1.4645, 1.4640; acid no. 1.8, 2.0, 1.8; ester no. 4.9, 6.8, 4.5 15 references. H. M. Burlage

Sulfanilamide. John R. Sampey. *Furman Bull.* **22**, No. 2, 3–13(1940).—A review with abstracts of patents and a bibliography of 117 references. E. J. C.

Drying and curing bright leaf tobacco with conditioned air. Albert H. Cooper, Carl D. Delamar and Henry B. Smith. *Ind. Eng. Chem.* **32**, 194–8(1940).—See *C. A.* **33**, 7489[2]. J. E. D. 8

Economy in salve bases. H. v. Czetsch-Lindenwald and F. Schmidt-La Baume. *Deut. Apoth.-Ztg.* **54**, 1110–11(1939).—Suggestions are offered how and to what extent certain substitutes may be employed in lieu of the usual bases in the prepn. of indifferent salves, salves with oil-sol. addns., salves with insol. or difficultly sol., and with H_2O-sol. addns. W. O. E.

Anodynes of the ancients. A. Süssenguth. *Pharm. Zentralle* **80**, 677–9(1939). W. O. E.

The more recent drug-plant literature. Heinz Harms. *Süddeut. Apoth.-Ztg.* **79**, 813–14, 817(1939).—A compilation is presented of the publications on domestic drug plants. W. O. E.

Drug plants of the German Homeopathic Pharmacopeia. Acalypha indica L. Herbert Schindler. *Süddeut. Apoth.-Ztg.* **79**, 822–4(1939).—This species is described together with 6 other species of the same genus in connection with their distribution, therapy and application. 24 references. W. O. E.

The evaluation of the acidity of powders of Veratrum viride by the Daphnia method. Isadore Cohen. *Am. J. Pharm.* **111**, 426–9(1939); cf. *C. A.* **33**, 4318[2].—The *Daphnia* method for the evaluation of powders of *Veratrum* is described. Biol. standardization of drug powders, solid exts., etc., whose activity is due to a complex rather than any one active agent, is necessary to insure the uniform potency of the final prepn. Two lots of *Veratrum viride* tested by this method have shown that one lot was 1.7 times more toxic than the other. It is obviously apparent that if the 2 lots of powdered *Veratrum viride* tested were extd. in accordance with the U. S. P. Standards the method of extn. alone could not guarantee the uniform potency of the prepns. The *Daphnia* method offers a rapid, inexpensive and accurate means of evaluating the activity of such substances which owe their activity to a complex especially when the locomotion of the *Daphnia* is visibly affected in their presence. W. G. Gaessler

Efficiency of bactericidal agents in different ointment bases. Louis Gershenfeld and Russell E. Brillhart. *Am. J. Pharm.* **111**, 430–42(1939); cf. *C. A.* **27**, 3734.—A report is given on an investigation of 48 ointments checked by the U. S. Food & Drug Administration agar plate and agar cup plate techniques. The tests indicated that bactericidal agents used in the newer water-miscible ointment bases produced greater bacteriostatic action as revealed by the production of inhibition zones than in the older type of bases when tested by the F. D. A. agar plate and agar cup plate techniques. W. G. Gaessler

A new approach to the standardization of digitalis. Arno Viehoever, N. H. Sokoloff and A. A. Taransky. *Am. J. Pharm.* **111**, 466–74(1939).—Digitalis leaf exhibits protective action on the heart of *Daphnia magna* against depressants (e. g., yohimbine). The degree of protection appears to be directly proportional to the amt. of digitalis. Mixts. of digitalis glucosides exhibit the same protective action. Further work is necessary fully to explore the feasibility of this method for assay purposes. W. G. G.

Qualitative and quantitative analysis of the inorganic constituents of the flowers of Opuntia ficus indica and the decoction of the flowers. Carmelo Battaglini. *Ann. chim. farm.* (Suppl. to *Farm. ital.*) Dec., 1939, 70–3.—Analyses of the ash of the flowers and decoction of the flowers of this Mexican cactus are given. The K content is high. The decoction acts as a diuretic, probably because of the high K content. L. E. Gilson

Comparison of the rates of diffusion, in distilled water, of various salts of *p*-aminobenzoyldiethylaminoethanol (procaine base). Jean Régnier and André Quevauviller. *Compt. rend. soc. biol.* **132**, 219–22(1939); cf. *C. A.* **33**, 6379[3], 7887[1].—The rates of diffusion of the salts decreased in the order: HCl salt, benzoate, citrate, phenylpropionate, gluconate. **Passage of different salts of procaine base through a cellophane membrane. Effects of time and concentration on the diffusion of the hydrochloride.** Jean Régnier, André Quevauviller and André Fieyre. *Ibid.* 252–5. L. E. Gilson

Bactericidal action of x-rays in the presence of dyes. Chien-Liang Hsu and T. T'ung. *Proc. Soc. Exptl. Biol. Med.* **42**, 828–30(1939).—Mercurochrome, eosin and methylene blue exerted a bactericidal action on numerous 9 pathogenic Gram-pos. organisms concurrently exposed to x-rays. L. E. Gilson

Chemical and biological assays of the tertiary alkaloids, quaternary bases, and galenical preparations of Phaeanthus ebracteolus (Presl) Merril. Faustino Garcia and Araceli A. Ylagan. *Rev. filipina med. farm.* **30**, 457–64 (1939).—Methods are discussed. L. E. Gilson

Comparative disinfecting action of Sepso tincture and [illegible] of iodine. Karl Wurm. *Z. Immunitäts.* **96**,

193–216(1939).—Sepso tincture, an alc. soln. of complex compds. of certain metals with Br and bromic acid, is offered as a substitute for the tinct. of I. It is slightly less active as a disinfectant than the tinct. of I but *Bacillus prodigiosus* sown on the skin are killed by it very quickly. Its advantages are less toxicity and less corroding action on metals. Julian H. Lewis

Beauty in poisons. Victor Lewitus. *Am. Druggist* **100**, 24–5(Oct., 1939).—Photomicrographs are given of acetanilide, As_2O_3, boric acid, caffeine (2), $CuSO_4$, dinitrophenol, dionine, ephedrine sulfate, hexamethylenetetramine, oxalic acid, KCl, $KMnO_4$, NaCl, strychnine sulfate, stypticin, sulfanilamide and tartar emetic. J. P.

A practical guide to the use of pharmaceutical flavors. Geo. C. Schicks. *Druggists' Circ.* **83**, 28–9(Oct., 1939). J. Pinchack

The composition of some commercial contraceptive jellies. Leo Shedlovsky and Harry Bodner. *J. Contraception* **4**, 179–88(1939).—Methods of analysis are briefly described and results are tabulated for 75 jellies and creams. More than half of the jellies were found to be modified starch glycerite or gum glycerite jellies with boric and lactic acids. In so far as a jelly depends on pH for its spermicidal effect, it appears desirable to have a high buffer capacity; about half of the jellies tested appeared to be of this type. Surface-active materials were found in nearly all the creams but very few jellies. J. P.

Some useful prescriptions. Bernard Fantus. *J. Lancet* **60**, 25–9(1940).—Formulas are given for several analgesic, antiasthmatic and cardiosedative capsules contg. aspirin, pyramidone and carbromal, resp., as major ingredients. Several examples follow on the value of sirups of acacia, licorice, cherry, cinnamon and *Eriodictyon* in disguising unpleasant tastes of prescriptions. The term "iso-elixir" is suggested in writing prescriptions for alc. liquid extractives. It signifies mixing the "low-alc. elixir" and the "high-alc. elixir" in such proportion as to equal the alc. strength of the liquid galenical or chemical that is to be dissolved. The vehicle value of glycerol is illustrated in several hypnotic and diuretic prepns. A formula for compd sirup of NH_4 mandelate is submitted; it consists of 1 g. sol. saccharin, 50 g. NH_4Cl, 80 g. $(NH_4)_2CO_3$, 200 g. mandelic acid, 400 g. sucrose, 0.04 cc. benzaldehyde, 0.1 cc. fennel oil, 1 cc. anethole, 175 cc. licorice fluidext. and water to make 1000 cc. J. Pinchack

Nasal preparations. Milton A. Lesser. *Chem. Products* **2**, 151–4, 160(1939).—The compns. of various pharmaceutical formulas are given. Leopold Scheflan

Chemical aspects of skin treatment. C. R. Theiler. *Chem. Products* **3**, 13–16(1939).—A discussion of the types of medicaments, dusting powders, liquid suspensions, lanolin, skin secretions and mineral lubricants. Leopold Scheflan

Chemical composition of Indian senna leaves (Cassia angustifolia). P. Bhaskara Rama Murti and T. R. Seshadri. *Proc. Indian Acad. Sci.* **10A**, 96–103(1939).—With regard to the conflicting reports respecting the compn. of Indian senna leaves a detailed chem. examn. of leaves obtained from Koilpatti in the Tinnevelly District was made. An aq. ext. of the leaves contains a considerable amt. of Ca salts. In the ash (forming 9.6% of the leaves) are detectable Fe, Mn, Ca, Mg, K, Na, phosphate, sulfate, carbonate, chloride and silicate. The amts. of the important components are (in terms of the oxides): SiO_2 2.7, MgO 7.2, CaO 31.6 and P_2O_5 3.6%. For the isolation of the org. compds. the leaf powder is first extd. with petr. ether. This ext., after removal of the petr. ether and purification of the residue with benzene, gives free myricyl alc. admixed with wax. For the sepn. of the flavonols the alc. ext. of the leaf powder previously extd. with petr. ether is treated with water which dissolves the flavonols. These are pptd. as lead salts. The free flavonols (0.1% of the leaves) are sepd. by fractional crystn. from alc. into the less sol. isorhamnetin and the more sol. kaempferol. For the isolation of the anthraquinone derivs. the residue of an alc. ext. of leaf powder previously extd. with petr. ether is extd. with hot benzene which, after purification, gives rhein in a yield of 0.03% of the leaves. If the alc. ext. is boiled with HCl prior to the extn. with benzene the yield is 0.07%, indicating the existence of a rhein glucoside in the leaves. The remaining benzene soln. contains small amts. of emodin. Dora Stern

Pharmaceutical iodine compounds. Dr. Wander Gyorgyszerés Tápszergyár R. T. Hung. 121,544, Sept. 15, 1939. Compds. suitable for parenteral administration can be produced by treating 1,3-dipiperidyl-2-propanol with alkali iodides, with or without solvents.

Therapeutic composition containing insulin. David A. Scott and Albert M. Fisher (to Governors of The University of Toronto). U. S. 2,179,384, Nov. 7. A compn. contg. insulin, protamine and Zn is suitable for blood-sugar-lowering action—Cd, Ni or Co also may be used. Cf. *C. A.* **33**, 3076[9].

Therapeutic bismuth compound solutions. Clarence W. Sondern and Geo. O. Doak (to Geo. A. Breon & Co.). U. S. 2,178,126, Oct. 31. A soln. of stable character, being free from decompn. products after normal periods of storage, and relatively stable against light, adapted for intramuscular injection in the treatment of syphilis, comprises an aq. soln. of an alkali metal Bi saccharate and sugar in amt. sufficient to render the soln. substantially hypertonic.

Strophanthus glucoside. Arthur Stoll and Jany Renz (to Chemische Fabrik vorm. Sandoz). U. S. 2,179,204, Nov. 7. For the prepn. of *k*-strophanthoside, an ext. rich in the glucoside is made by treating the seeds of *Strophanthus kombé* with EtOH or a mixt. of EtOH and $CHCl_3$, the soln. thus obtained being evapd. and the residue treated with an acetylating agent such as Ac_2O to form a heptaacetyl compd. of the glucoside which is then sepd. by fractional crystn. and sapond. by treatment with a nonaq. soln. of an alcoholate such as a soln. of $Ba(OMe)_2$ in MeOH, followed by crystn. of the glucoside. Cf. *C. A.* **33**, 3401[1].

Nuclear-substituted derivatives of the morphine series. Lyndon F. Small and Howard M. Fitch (to the Government of the U. S. A. as represented by the Secretary of the Treasury). U. S. 2,178,010, Oct. 31. The compds.

methyldihydrothebainone, $C_{19}H_{25}O_3N$; isomethyldihydrothebainone, $C_{19}H_{25}O_3N$; methyldihydrocodeinone, $C_{19}H_{23}O_3N$; isomethyldihydrocodeinone, $C_{19}H_{23}O_3N$; methyldihydrocodeinone enol acetate, $C_{21}H_{25}O_4N$; isomethyldihydrocodeinone enol acetate, $C_{21}H_{25}O_4N$; methyldihydromorphinone, $C_{18}H_{21}O_3N$; methyldihydromorphine, $C_{18}H_{23}O_3N$; isopropyldihydromorphinone, $C_{20}H_{25}O_3N$; amyldihydrothebainone, $C_{23}H_{33}O_3N$; amyldihydrocodeinone, $C_{23}H_{31}O_3N$; amyldihydromorphinone, $C_{22}H_{31}O_3N$; benzyldihydrothebainone, $C_{25}H_{29}O_3N$; phenyldihydrothebainone, $C_{24}H_{27}O_3N$, are obtainable by reacting a substance from the group consisting of the enol ethers and enol esters of dihydrocodeinone with a Grignard reagent the org. radical of which corresponds to the substituent named, hydrolyzing the resulting product to produce a dihydrothebainone substituted by the org. radical of the Grignard reagent, and, where necessary, converting the resulting substituted dihydrothebainone to the correspondingly substituted named morphine deriv. Benzene may be used as a solvent in prepg. these compds., and numerous details of procedure are given. The products may be used as therapeutic narcotics and are relatively free from undesirable respiratory and emetic effects.

Alkyl guaiacols. Roland R. Read (to Sharp & Dohme, Inc.). U. S. 2,178,608, Nov. 7. *tert*-Hexyl guaiacol, distg. 275–290°, is produced by heating guaiacol and *tert*-hexyl alc. at 100–130° in the presence of $ZnCl_2$ and HCl. It is a germicidal compd., as are also: *sec*-Bu guaiacol, b. about 245–270°; *sec*-Am guaiacol, b. about 250–268°; *sec*-hexyl guaiacol, b. about 255–275°; and cyclohexyl guaiacol, b. about 300 308°.

Organic mercury compounds. Karl Görnitz, Willy Harnack and Otto Wurm (to Schering A.-G.). U. S. 2,178,099, Oct. 31. By effecting reaction between a sol. Hg salt such as mercuric acetate, nitrate, chloride or sulfate and an unsatd. hydrocarbon contg. an ethylene linkage, such as C_2H_4, C_3H_6, or cyclohexene or methylcyclohexene, with a halogenated aldehydic carbonyl compd. such as chloral hydrate, chloral, bromal or trichloroacetaldehyde ethyl semiacetal or chloral methyl semiacetal, in the presence of a lower aliphatic alc., *disinfectant* and *fungicidal compds.* are produced such as: α-trichloro-β-hydroxy - β - (acetoxymercuriethoxy)ethane, α - trichloro-β - ethoxy - β - (acetoxymercuriethoxy)ethane, α - trichloro - β - ethoxy - β - (nitratomercuriethoxy)ethane, α-trichloro - β - methoxy - β - (acetoxymercuriethoxy)-ethane, α - trichloro - β - isopropoxy - β - (acetoxymercuriethoxy)ethane, α - trichloro - β - butoxy - β - (acetoxymercuriethoxy)ethane, corresponding isoamyl and bromo compds., α-trichloro-β-ethoxy-β-(acetoxymercuriisopropoxy)ethane, α - trichloro - β - methoxy - β-(acetoxymercuricyclohexyloxy)ethane, and the like.

Concentrated, stable pyelographic solutions. Iván Egger. Hung. 122,081, Nov. 15, 1939. The concd. aq. soln. of the sodium salts of iodine-contg. org. acids is stabilized by 0.5–10.0% (preferably 5%) triethanolamine.

Diuretics suitable for rectal administration. Chinoin Gyógyszer- és Vegyészeti Termékek Gyára R. T. (Kereszty és Wolf) Hung. 122,012, Nov. 15, 1939. Org. compds. contg. Hg fixed to a C atom of an aliphatic side chain, and contg. also a carboxyl group, are made to react with theophylline in soln. in an org. solvent (preferably $CHCl_3$). The alkali or alk. earth salts of the product may be formed and added to cacao butter as filler.

Isolating follicle hormones from the urine of pregnant individuals. Erwin Schwenk and Friedrich Hildebrandt (to Schering A.-G.). U. S. 2,178,109, Oct. 31. A method of isolating follicle hormones from crude solns. contg. small amts. of follicle hormones together with a relatively large amt. of other substances of diverse character which normally accompany the hormones comprises subjecting the starting material to a steam distn. whereby the volatile phenols are removed, treating the same with compds. of alk. reaction whereby the neutral impurities are rendered insol., acylating the pretreated material in alk. soln. and saponifying the acylation products obtained thereby.

Tooth filling. Wm. G. Turner. U. S. 2,178,821, Nov. 7. A soln. for satg. a fibrous filling such as absorbent cotton for solidifying and hardening when subjected to water is prepd. from gum sandarac 3 lb., gum camphor 2 oz., methyl salicylate 2 oz., thymol 2 oz. and alc. 2 qts.

Adsorptive filter for removing nicotine and other toxic ingredients from tobacco smoke. Ödön Páll. Hung. 121,494, Sept. 15, 1939. The active ingredient of the filter is a loose mass of silica gel moistened with a 5% aq. soln. of boric acid; or, the grains of the gel may be covered by a solid layer of boric acid.

Selecting tobacco types on the basis of their nicotine contents. László Barta. Hung. 121,978, Nov. 2, 1939. Sections of the same size, cut from tobacco leaves, are rubbed with sand or glass powder, washed into a test tube, treated with CNBr and an amine (e. g., β-naphthylamine), shaken, and allowed to stand for 1–2 hrs., and the color intensities are detd. The tobacco plants showing the darkest red colors are selected for further planting.

18—ACIDS, ALKALIES, SALTS AND OTHER HEAVY CHEMICALS

E. M. SYMMES

History of [oil of] vitriol manufacture in England. H. W. Dickinson. *Trans. Newcomen Soc.* 18, 43–60(1937–38). E. H.

The concentration of spent sulfuric acid containing organic admixtures. D. A. Kuznetsov and M. I. Rusakova. *Trudy Inst. Khim. Tekhnol. Mendelejeff. chem.-tech. Inst.* 1938, No. 3 4, 28–36; *Khim. Referat. Zhur.* 2, No. 4, 88(1939). The concn. of H_2SO_4 contg. org. admixts. was studied in order to det. the possibility of re-use of H_2SO_4. The H_2SO_4 was placed in a Würz flask on an elec. plate, into which hot air was passed. The flask was connected with a condenser. For comparison, the following substances were concd.: dil. pure H_2SO_4 soln., a mixt. of H_2SO_4 36, C_2H_5OH 19, H_2O 45%, spent H_2SO_4 of the iso-PrOH production process with a H_2SO_4 concn. of 40–80, and 93%, and spent H_2SO_4 from the iso-BuOH production process with a H_2SO_4 concn. of 15–60, and 80%. Repeated returns of the spent H_2SO_4, after concn; to the production process caused a gradual increase of org. admixts. With increase of the content of org. admixts. decompn. of H_2SO_4 is increased, while temp. of decompn. is lowered. The loss of H_2SO_4 was small in all expts. The max. loss from decompn. of H_2SO_4 was 1.83%, while the total loss was about 3%. The sepn. of resin substances on the walls of the app. is a considerable disadvantage of the concn. process. W. R. Henn

Sodium carbonate; granular (monohydrate crystals). *Federal Specification* O-S-581a, June 29, 1939. **Soda, laundry; modified (washing soda).** *Ibid.* P-S-641a, June 29, 1939. Washington: Supt. of Documents, U. S. Govt. Printing Office, 5¢ each. L. Wilson Greene

Anhydrous sodium hydroxide. Production by partial pressure evaporation. Donald F. Othmer and Joseph J. Jacobs, Jr. *Ind. Eng. Chem.* 32, 154–60(1940).—Anhyd. NaOH was prepd. continuously from 50% aq. solns. on a pilot scale, with kerosene as diluent in the evapn. Kerosene remaining on the solid NaOH was removed by centrifuging and solvent washing. The total, calcd. heat cost was about 350 lb. of coal per ton of 50% NaOH soln., or about 150 lb. from a 70% NaOH soln., i. e., 1/3 the present cost. Because of the protective film from the kerosene, no corrosion of equipment was found. Steel equipment might be used. The NaOH produced was a fine, cryst. powder, free-flowing and of rapid chem. activity because of great surface area. E. M. Symmes

Thiodiglycol. Unit process and operations involved in its synthesis from ethylene oxide and hydrogen sulfide. Donald F. Othmer and Donald Q. Kern. *Ind. Eng.*

Chem. **32**, 160–9(1940).—The Meyer synthesis (*Ber.* **19**, 3259 (1886)) is expensive. In production from $(CH_3)_2O$ and H_2S the gas-phase reaction is extremely slow, but after soln. in thiodiglycol (I) the gases react rapidly. The reaction is of the third order. With simple app., data useful for manuf. on a large scale were obtained, and I was produced in almost theoretical quantities when the gases were supplied in correct, mol. proportions. E. M. Symmes 1

Removal of oxygen from gases by means of active copper. F. R. Meyer and Grete Ronge. *Angew. Chem.* **52**, 637–8(1939).—Highly active Cu prepns. were made from $CuCO_3$-$Cu(OH)_2$ mixts. by dissolving in concd. NH_4OH and from $CuCl_2.2H_2O$ and NaOH. Both prepns. were pptd. on infusorial earth and activated with H_2 *in situ*. Diagrams of the absorption tower and the app. used for O_2 detn. are shown. Use and regeneration of the Cu prepns. are possible at about 200°. A Ni prepn. likewise gave good results. An ammoniacal soln. of $Fe(OH)_2$ was used for the detn. of O_2. Karl Kammermeyer 2 3

Price and production policies in the sulfur industry. Carey C. Thompson. *Furman Bull.* **22**, No. 2, 24–32 (1940). E. J. C.

The application of ion exchangers having an artificial resin basis to the desalting of waters. A. Richter. *Angew. Chem.* **52**, 679–81(1939); cf. Griessbach, *C. A.* **33**, 4746[5], 8417[5].—Examples of partial and complete desalting by the use of "wofatite" H and (OH) exchangers are discussed. Exptl. data show successful operation, e. g., reduction of total solids from 1400 mg./l. to 45 and 13 mg./l. for single and double desalting, resp. K. Kammermeyer 4

Oxidation of arsenious acid. S. M. Golyand, S. I. Libin and A. A. Sokov. Russ. 51,903, Oct. 31, 1937. H_3AsO_3 is oxidized to H_3AsO_4 by air in the presence of pyrolusite. 5

Boric acid. I. N. Kostyukovskiĭ. Russ. 52,048, Aug. 31, 1937. In the prepn. of H_3BO_3 from ascharite, the crystn. and the sepn. of $MgSO_4$ are accelerated by adding to the mother lye $Mg(OH)_2$ or $MgCO_3$ or substances forming the latter with $MgSO_4$ in amts. sufficient for the combination of free H_3BO_3.

Fluosilicic acid. I. G. Russ. Russ. 51,906, Oct. 31, 1937. H_2SiF_6 is prepd. by treating a mixt. of fluorspar and hydrated SiO_2 with a 20–40% H_2SO_4 at a temp. not exceeding 90°. 6

Hydrocyanic acid gas generator of the cyanide feed type. Kenneth W. Goulet. U. S. 2,178,372, Oct. 31. Various structural and operative details.

Nitrates or nitrites in the manufacture of sulfuric acid. Lajos Solt. Hung. 121,393, Sept. 1, 1939. Nitrates or nitrites are used instead of nitric acid. Their aq. solns. are led through a reaction column, centrifuge or other app. and decompd. by sulfuric acid or vapors of SO_2. The nitrous gases formed are used in the ordinary manner. 7

Recovery of sulfur dioxide from gases. George H. Gleason and Alfred C. Loonam (to Guggenheim Bros.). Can. 385,341, Nov. 28, 1939. In the recovery of SO_2 from gases by absorption in a medium consisting essentially of dimethylaniline, to release the SO_2 the soln. is heated to higher than 100° under greater than atm. pressure. An app. is described. 8

Alkali carbonates. Ya. E. Seferovich. Russ. 52,077, Oct. 31, 1937. Alkali nitrates are treated with NH_4 carbamate and liquid NH_3. The alkali carbamate formed is sepd. and converted to carbonate by means of superheated steam. 9

Aluminum fluoride; cryolite. N. A. Ivanov, G. S. Morozov and G. V. Labutin. Russ. 51,940, Oct. 31, 1937. A mixt. of alunite and CaF_2 is leached with H_2O and the product converted by NH_4OH or Na_2CO_3 to basic Al fluoride. This is heated to distil off AlF_3 or converted to Na_3AlF_6 by fusion with Na_2CO_3.

Aluminum fluosilicate. V. G. Shcherbakov. Russ. 51,957, Oct. 31, 1937. $Al(OH)_3$ is dissolved in a mixt. of HF and H_2SiF_6 and SiO_2 is added. The reaction mass is cooled and Al fluosilicate sepd. in the usual manner.

Ammonium sulfate. John W. R. Rayner (to Imperial Chemical Industries Ltd.). U. S. 2,178,082, Oct. 31, $(NH_4)_2SO_4$ is crystd. from a soln. in the presence of trivalent Fe, Al or Cr cations and oxalic anions, which serve to control the form and size of crystals produced.

Lead and lead oxide composition. Andrew Mayer (to National Lead Co.). Can. 385,766, Dec. 19, 1939. A bath of molten Pb is kept in rapid motion in a pot against a fixed baffle, with air admitted for contact with the Pb suspended above the bath, and the bath maintained at 700–850°F.

Magnesium hydroxide. Fritz Wienert (to Magnesium Development Corp.). U. S. 2,178,983, Nov. 7. A calcined raw material contg. at least a substantial proportion of CaO, such as a calcined lime or dolomite, is slaked with an aq. soln. contg. an alkali metal or alk. earth metal nitrate, alkali metal chlorate or $CaCl_2$, together with a minor proportion of boric acid or an alkali borate, and the resulting suspension is treated with $MgCl_2$ soln.

Silicon carbide. Raymond C. Benner, Romie L. Melton and John A. Boyer (to Carborundum Co.). U. S. 2,178,773, Nov. 7. A mixt. of sand and C is passed through a tubular furnace chamber, the central portion of which is heated to at least the temp. of formation of SiC, and the mixt. is maintained out of contact from the walls of the furnace in the cooler portions of the furnace chamber, to prevent sticking and produce a product composed of individually sepd. crystals of SiC substantially free from faces produced by artificial fracture.

Soda preparation. István Steiner. Hung. 121,391, Sept. 1, 1939. Ammonia soda is dissolved in water, purified by filtration, sedimentation, etc., and evapd. *in vacuo*. Water glass may be added to improve its washing effect.

Purifying caustic soda. Irving E. Muskat and Wm. F. Waldeck (to Pittsburgh Plate Glass Co.). U. S. 2,178,694, Nov. 7. An impure aq. soln. of NaOH substantially satd. with NaCl is concd. so that monohydrate will crystallize, cooled to crystallize a substantial quantity of both relatively coarse hydrated NaOH and relatively fine NaCl crystals, and such coarse and fine materials are sepd. by passing the resulting liquor with which they are assocd. through a filter of suitable porosity.

Sodium hyposulfite. M. N. Merlis. Russ. 52,052, Oct. 31, 1937. $Na_2S_2O_4.2H_2O$ is prepd. from Na formate by treatment with aq. soln. of SO_2.

Sodium phosphate. Ya. I. Mikhailenko and A. P. Kreshkov. Russ. 51,896, Oct. 31, 1937. Ferrophosphorus is fused with pyrite and the melt is extd. with HCl. The ext. is treated with NaOH to form Na phosphate and ppt. $Fe(OH)_3$.

Sodium plumbite doctor solution. Joseph E. Drapeau, Jr. (to Glidden Co.). U. S. 2,178,742, Nov. 7. A Na plumbite doctor soln. contg. a higher percentage of Na plumbite than can normally be maintained in aq. soln. comprises a soln. of PbO in an excess of NaOH over that necessary to form Na plumbite with the PbO, and between 0.25% and 5%, based on the PbO content, of a water-sol. polyhydroxy acid, such as tartaric acid, a water-sol. salt of a polyhydroxy acid in which the cations are univalent, such as Na K tartrate, a water-sol. polyhydroxy alc. or phenol or a water-sol. sucrose.

Stannic oxide. Ákos Pintér. Hung. 122,067, Nov. 15, 1939. Sn is heated with S vapors to form the sulfide, and the sulfide is oxidized to SnO_2.

Decolorizing titanium tetrachloride. Frederick Gage (to Pittsburgh Plate Glass Co.). U. S. 2,178,685, Nov. 7. Decolorization is effected by contact with a lower-valence Ti compd. such as $TiCl_3$ or $TiCl_2$ (suitably at 135° for 2–4 hrs.).

Zinc oxide. Richard W. French (to Superior Zinc Corp.). Can. 384,730, Oct. 17, 1939. By-product Zn residue contg. an alkali metal salt, a substantial amt. of $ZnCO_3$ and combined S is heated with water to dissolve the alkali metal salt, the residue calcined under oxidizing conditions to convert $ZnCO_3$ and any S compd. mainly into $ZnSO_4$, ZnO and SO_2, the sulfate removed by washing, and the ZnO ground.

Zirconium hydroxide. Ya. M. Pesin. Russ. 49,075, Oct. 31, 1937. Acidic solns. of Zr salts contg. also salts of Fe, Al, etc., are partially neutralized at boiling temp. to the extent that the ratio of acid to total oxide is 0.35–2.0. In this range, $Zr(OH)_4$ ppts. with a small amt. of Fe; the other metals remain in soln.

Carbon dioxide. Ralph H. McKee and James W. Martin (to Macmar Corp.). U. S. 2,178,968, Nov. 7. A soln. of $KHCO_3$ is heated while there are suspended in it sharp-edged, inert particles, such as ground coke which serve to facilitate the liberation of CO_2. App. is described.

Hydrogen peroxide. John C. Michalek and Edward C. Soule (to Mathieson Alkali Works, Inc.). U. S. 2,178,640, Nov. 7. *p*-Hydrazotoluene is used as the reduced intermediate subjected to oxidation in the manuf. of H_2O_2 by cyclic oxidation and reduction of an intermediate in a solvent, such as benzene, in which H_2O_2 is of limited soly.

Highly concentrated hydrogen peroxide solutions. Heinrich Schmidt (to Pennsylvania Salt Mfg. Co.). U. S. 2,178,496, Oct. 31. App. is described, and a process which involves bringing into intimate contact a mixt. of water and H_2O_2 vapors and an aq. soln. of H_2O_2 contg. at least 10% of H_2O_2, so as to effect condensation of at least a portion of the H_2O_2 vapor, while at least a portion of the water vapor remains uncondensed.

Hydrogen-nitrogen mixtures. Lee C. Updegraff (to Dominion Oxygen Co., Ltd.). Can. 384,432, Oct. 3, 1939. In producing H-N mixts. by reaction of a mixt. of air with excess hydrocarbon and treating the combustion products with steam in the presence of catalyst, the ratio of H to N is increased to at least 0.4 and the H efficiency raised to at least 80% by adjusting the ratio of hydrocarbon to O to about 4 atoms of C to 5 mols. of O, enriching the air with O, and keeping the ratio of hydrocarbon to O substantially unchanged.

Apparatus for producing hydrogen-nitrogen mixtures. Hendrik D. Erasmus (to Union Carbide and Carbon Research Laboratories, Inc.). U. S. 2,178,833, Nov. 7; Can. 384,470, Oct. 3, 1939. An app. for the production of mixts. of H and N suitable for use in the "bright annealing" of metals, from raw materials comprising hydrocarbons or material contg. hydrocarbons, mixts. of O and N, and steam, comprises a combustion chamber substantially filled with a mass of lump refractory material having an av. space factor of about 50%, the refractory mass being arranged in a series of concentric layers, each of which is composed of lumps of substantially the same size, the layers being graded progressively from relatively larger-sized lumps near the center of the chamber to relatively small-sized lumps near the periphery of the chamber; means for introducing combustion gases in a diffuse manner well within the body of the mass of refractory material, a steam jacket surrounding the combustion chamber in a concentric manner, and connecting with the discharge opening thereof, means for introducing steam into the steam jacket, a catalyst chamber contiguous to the combustion chamber and steam jacket and freely connected with the outlets therefrom, a porous mass of catalyst material substantially filling the catalyst chamber, baffle means between contiguous chambers, and means for removing and for scrubbing gases which have passed through the catalyst chamber.

Recovery of sulfur from gases. Conway von Girsewald, Gerhard Roesner and Josef Barwasser (to American Lurgi Corp.). Can. 384,396, Oct. 3, 1939. A gas contg. SO_2 is passed through a layer of fuel in a shaft furnace, without external heating, at such speed that free SO_2 is not contained in the effluent gas and the temp. of the effluent gas at its outlet point from the fuel does not reach 800°. The effluent gas is mixed with the necessary amt. of SO_2 for the conversion of the S still contained in it into the elementary form, with the simultaneous oxidation of the CO present to CO_2, and the resulting gas mixt. is subjected to secondary treatment with a catalyst at an elevated temp.

Decomposing bauxite. Vereinigte Aluminium-Werke A.-G. Brit. 506,885, June 6, 1939. In the Bayer process for the alk. decompn. of bauxite, make-up alkali is added in dil. soln. to the red mud to be washed. The alkali is preferably prepd. by causticizing Na_2CO_3 with CaO and added, together with the lime mud, to the red mud, the mixt. being thickened and then filtered. The dil. lye obtained is restored to the tank in which the concd. aluminate lye is dild. before the red mud is sepd. Cf. *C. A.* **33**, 3981[9].

Thermal decomposition of dolomite. Harold S. Booth. Can. 385,398, Dec. 5, 1939. Dolomite is brought into contact with molten NaCl, KCl, LiCl, $CaCl_2$ or alkali sulfate or mixts. thereof at a temp. between 360° and the decompn. temp. of $CaCO_3$.

Carbon blacks and lampblacks. Wm. B. Wiegand (to Columbian Carbon Co.). U. S. 2,178,382, Oct. 31. For producing a "nondeactive" heat-treated black in granular form, the black is caused to adsorb sufficient fixed alkali so that it has an "aq. sludge pH" of from about 6.0 to about 9.0, being thereafter converted to the granular form. U. S. 2,178,383 relates to products of like character having a normal O content and being free from added S acids, Se, Te and halogens, free or combined. Such products are suitable for use in paints, lacquers, rubber compns., etc.

Molybdenum catalyst for the hydrogenation of heavy hydrocarbons. V. F. Popov and S. B. Anisimov. Russ. 52,082, Oct. 31, 1937. Addn. to Russ. 42,982 (*C. A.* **31**, 7206[2]). Sol. salts of molybdic acid (e. g., NH_4 paramolybdate) are treated according to Russ. 42,982.

Silver catalysts. Gerardus H. Visser (to Shell Development Co.). Can. 384,172, Sept. 19, 1939. A highly active Ag metal catalyst is prepd. by electrolytically reducing an aq. soln. of an Ag compd., e. g., $AgNO_3$, to Ag in the presence of nascent H generated in the aq. medium.

19—GLASS, CLAY PRODUCTS, REFRACTORIES AND ENAMELED METALS

G. E. BARTON AND C. H. KERR

Glasses, gage; flat (plain and reflex) (for pressures 125 pounds and over). *Federal Specification* DD-G-491, June 29, 1939. **Glasses, gage; reflex and round, tank (for pressures under 125 pounds).** *Ibid.* DD-G-496, June 29, 1939. **Glasses, gage; round, boiler (for pressures 125 pounds and over).** *Ibid.* DD-G-511, June 29, 1939. Washington: Supt. of Documents, U. S. Govt. Printing Office, 5¢ each. L. Wilson Greene

Note on the solubility of sodium chloride in a soda-lime-silica glass. H. Marshall Bateson and W. E. S. Turner. *J. Soc. Glass Tech.* **23**, 265–7(1939).—By melting increasing and excessive amts. of NaCl in the batches, it was found that a soda-lime-silica glass of initial compn. SiO_2 75, CaO 9.2 and Na_2O 15.8% dissolved NaCl at 1400° in amt. equiv. to 1.42% of Cl or 2.34% NaCl. H. F. Kriege

Flameless heating of glass-melting furnaces. N. P. Krasnikov. *Stekol'naya Prom.* 1938, No. 10, 25–6; *Khim. Referat. Zhur.* 2, No. 4, 104(1939).—In heating glass-melting furnaces by flameless burners which used purified peat "generator" gas, a high productivity of the furnace and a low consumption of fuel were obtained. W. R. Henn

Study of the possibility of reducing the iron oxide content of molten soda-lime-silica glasses by the action of chlorides. H. Marshall Bateson and W. E. S. Turner. *J. Soc. Glass Tech.* **23**, 253–64(1939).—Meltings have been made, mainly at 1400°, in Pt, of a glass of basic compn. SiO_2 75.0, CaO 9.2, Na_2O 15.8%, to which either 0.1 or 0.2% of iron oxide as Fe_2O_3 in the glass was added and the batch melted with the addn. of one of the chlorides, $FeCl_3$, NaCl, KCl or NH_4Cl, in amt. equiv., in terms of Cl, to 0.1, 0.2 or 0.4% of the glass. Analysis of the resultant glasses showed that during the melting process Fe as well as Cl was lost by volatilization, probably as $FeCl_3$, the

losses being very variable, but being, in general, lowest with NaCl and greatest with NH_4Cl. In no case did the loss of iron oxide reach 25% of the original amt., and, with NaCl, in no case did it reach 10%. Although NH_4Cl was the most effective of the reagents in eliminating iron oxide, its use in practice would be of doubtful benefit owing to its tendency to produce coloring effects varying from yellow to brown. H. F. Kriege

Cooling of flat glass. H. Yamamoto. *Glastech. Ber.* 17, 301–2(1939).—Flat glass prepd. by the Fourcault and the Pittsburgh vertical draw processes was examd. by means of a polariscope. The Fourcault glass showed noticeable strain only in narrow uniform bands along the edge, while in the Pittsburgh glass the bands were broader and the strain was frequently found in the center. The temp. distribution was detd. during operation by bringing the glass at various points into contact with a thermocouple, thus making it possible better to control cooling conditions. J. F. Hyde

Some experiments on the effects of humidity on the weathering of bottle glasses. Violet Dimbleby and W. E. S. Turner. *J. Soc. Glass Tech.* 23, 242–52(1939).—The alkali extd. from the interior of 3 different brands of 4-oz. medicine bottles by boiling for 5 hrs. with water was detd. very soon after the bottles had been made. Other bottles of each brand were then stored (some with interior as received, some after being washed) for a period exceeding 11 months, some at 25° in specially constructed chambers contg. P_2O_5 (and therefore of zero humidity), some in similar chambers at const. relative humidity of 76%, and some, with mouths covered by muslin, in a room subject to normal variations of atm. temp. and humidity. Observations of appearance were made throughout the period. At the end the acidity or alky. of interior and exterior was detd., and the general durability of the interior re-detd after a preliminary washing. The durability of bottles stored at zero humidity remained practically unchanged and no film of cryst. products of weathering was produced. Bottles exposed to a humid atm., either in an enclosed chamber or a room, developed cryst. films (more regular and finer when in the chamber) and the durability of the resulting surfaces was substantially improved as the outcome of such exposure. H. F. Kriege

The factory production of some special glasses for discharge lamps. P. Staton. *J. Soc. Glass Tech.* 23, 281–91 (1939).—The compns. of glasses suitable, on the one hand, for low-pressure and, on the other, for high-pressure mercury vapor lamps are set out and comments are made on the conditions to be observed in their com. prepn. Low iron oxide content is essential, especially in the hard glasses for high-pressure lamps, to ensure high transmission of ultraviolet light. Some expts. are recorded, showing that with certain borosilicate glasses the addn. of 0.5% NaCl to the batch resulted in an appreciable reduction in iron oxide content. Expts. are also recorded on a series of glasses of stated compn. contg. Co, Ni, Cu or Fe oxide or their mixts. designed to transmit ultraviolet light efficiently within certain wave-length limits and as little as possible visible light. The importance of wall thickness of the lamp bulb in this connection is referred to and the methods adopted for controlling the transmission are described. H. F. K.

Glass manufacture for electric lamps. The development of special glasses for mercury-discharge lamps. J. E. Stanworth. *J. Soc. Glass Tech.* 23, 268–80(1939).—Glasses contg. 5% boric oxide plus phosphoric oxide, 20–35% alumina, and 15% of the basic oxides, lime, baryta, magnesia, and zinc oxide, the remainder being silica, were studied with a view to finding suitable hard glasses for the inner tubes of high-pressure mercury-discharge lamps. Glasses of this type contg. more than approx. 27.5% alumina or more than approx. 7.5% lime, bubble too much during bench working in an oxy-coal gas flame. On the other hand, if the lime and alumina contents are too low, the glasses are difficult to found and work at the furnace. A glass of theoretical compn., SiO_2 56, Al_2O_3 24, CaO 7.5, BaO 7.5 and B_2O_3 5% has been melted on a semicom. scale in a small tank furnace constructed from china clayball clay blocks. Satisfactory lamps may be made from bulbs blown from this glass, and in addn. to having excellent lumen maintenance can be run horizontally without magnetic control. H. F. Kriege

Manufacture of colored glass of the Schott GG-3 type for filtering light. V. V. Vargin and L. O. Sarapin. *Optiko-Mekhan. Prom.* 7, No. 3, 9–14(1937).—The spectrum curve of B-Na glass (Schott GG-3) colored with CdS and Se is greatly affected by the Fe content of the glass. To obtain a steep spectrum curve, either the iron content must be lowered or the Cd content increased. Owing to the fact that Cd silicate is colorless the Cd surplus affects the curve very little. The color is chiefly detd. by sulfide S in the presence of a sufficient amt. of Cd; the former must not exceed 0.018 to 0.022%. Se affects absorption; a technically usable glass can be produced without Se. Because of a limited soly. of CdS and CdSe in glass, pptns. of black crystals may appear at too low melting temps. A greater part of Cd and S volatilizes during melting. Glass with a definitely steep curve of absorption can be obtained only with a definite regulation of the sulfide S content and careful thermal treatment; at higher temps. the limit of permeability is shifted to the red part of the spectrum. Partial or complete opalescence may appear when cooling in a large pot; the colloidal particles of pigments become largest at about 900°; to avoid opalescence, the glass should be heated to 1000° and rapidly cooled to 600°. Glass similar to the GG-3 type was produced with the addn. of 1 kg. $CdCO_3$ and 0.005 kg. Se for 100 kg. glass, at a temp. of 1400 and 1420° and after treatment at 660°. M. V. Condoide

Coloring of green bottle glass and the influence of the color on the workability. A. Dietzel. *Glastech. Ber.* 17, 303–6(1939).—The action of MnO_2 in bottle glasses is due to its high O content which is partially liberated at melting temps. and partly used in converting FeO to Fe_2O_3. There is a corresponding color change from blue-green to yellow-green. This is accompanied by improved thermal transmission through the glass during melting and lower heat reflection during working as shown by relative reflection measurements. Other oxidizing agents as As_2O_5 and CeO_2 have essentially the same effect as the MnO_2. J. F. Hyde

A study of the electrical resistance under varying conditions of some glasses and porcelains of possible utility for commercial insulators. Eric Seddon, W. J. Mitchell and W. E. S. Turner. *J. Soc. Glass Tech.* 23, 197–238(1939). —On 20 different glasses and 9 porcelains (glazed and unglazed), in the form of short rods, systematic measurements were made of the vol. resistivity *in vacuo* and of the surface resistivity under varying conditions, including temp. and humidity variation, and exposure, for varying periods of time extending to 12 months, to weathering in the atm. of a heavily industrialized neighborhood. Measurements on the weathered specimens were also made after the application to them of mech. and chem. cleaning processes. The degree of reproducibility of results was studied in detail. Wide variations in the surface resistivity of different specimens was the general experience whether after exposure to the ordinary atm. or to pure water vapor in a closed chamber. The vol. resistivity values of different specimens of any one material examd. *in vacuo* were in close agreement and remained practically const. with time; and the greatly varying resistivities of individual specimens were brought much closer; this shows the dominating effect of the film of moisture or dissolved electrolyte, the various forms of deposit losing potency in the absence of moisture. It was shown that a wide range of suitable glasses is available to meet the elec. requirements of telephone and telegraph insulators. H. F. Kriege

Effect of chemical pretreatment of glass surface on the silvering process. T. T. Nelman and B. N. Moskvin. *Optiko-Mekhan. Prom.* 7, No. 4, 8–10(1937).—A yellow-brown Ag layer consisting of sep. small crystals is formed shortly after silvering and pretreating the glass surface with $SnCl_4$, $TiCl_4$, $Th(NO_3)_4$, $AlCl_3$, $Pb(CH_3COO)_2$, methylene blue, or water; when $SnCl_2$ is used, a very thin blue layer appears on the surface which promotes the formation of mirrors. M. V. Condoide

Effect of chemical composition of silvering bath on the silvering process. B. N. Moskvin and T. F. Neiman. *Optiko-Mekhan. Prom.* 7, No. 3, 5–8(1937).—The effect of the concn. of reducing agents (inverted sugar with HNO_3) and of KOH and the effect of temp. on the ppn. of Ag when silvering were studied. The velocity of reduction was found to be most important. The best results were obtained with 0.5% and 1% concn. of the reducers (with a double amt. of $AgNO_3$). The temp. should lie between 13° and 18°. M. V. Condoide 2

The strength of glass-to-metal seals. C. J. Milner. *J. Soc. Glass Tech.* 23, 308–28(1939).—The results are based on bead seals of a particular glass on cylindrical wire of a metal which contracts more than the glass when cooled. It is found that the strength increases continually for increasing bead diam. on a given size of wire. For b/a (= bead diam./wire diam.) = 3, the strength is only 50% of that with b/a = 9. For const. b/a (= 9), the strength has a max. for a certain angle of contact of glass and metal of about 40°. For this angle the strength is about 20% greater than for angles of 0° or 90°. It is shown that, as a consequence of these results, the max. permissible stress measured at the center of a seal must depend on the shape and size of the seal. In favorable cases this max. may be considerably greater than the limit of 1 kg./sq. mm. laid down by Hull and Burger (cf. U. S. 2,167,482, *C. A.* 33, 8946[6]). Confirmatory expts. are described which show that the results may be applied to practical cases, and application to a particular case is discussed. H. F. K. 3

Apparatus for melting and fining glass. Games Slayter (to Owens-Illinois Glass Co.). Can. 385,354, Nov. 28, 1939. A batch of glass is melted at high temp., flowed in sheet formation, the gas bubbles are screened out, and the glass is flowed over a highly heated surface to cause dissolved gases to be evapd. 5

Electric heating of flowing molten glass. Leonard D. Soubier (to Owens-Ill. Glass Co.). U. S. 2,179,224, Nov. Means for regulating and controlling the temp. of molten glass as it flows through a predetd. length of a channel comprises an elec. resistor immersed in the glass in the channel, the resistor being in the form of a sheet metal plate comprising the floor and side wall portions of the predetd. length of the channel, the resistor being connected in circuit with a source of elec. current supply and having portions of varying thickness at different points lengthwise of the channel, whereby the elec. resistance is variable along the resistor so that a variable amt. of heat is supplied to the flowing glass at different points along the resistor. 6

Repair of furnace tanks or chambers holding molten glass or the like. Henry H. Blau and Kenneth K. Knaell (to Carborundum Co.). U. S. 2,178,134, Oct. 31. A repair method involves heating members of cast refractory such as blocks having a greater sp. gr. than the molten material in the tank or chamber to substantially the same temp. as such molten material, and depositing the heated members, which may be formed of Al_2O_3 and SiO_2, through the molten material in overlapping position to form a covering layer on a wall of the tank or chamber in contact with the molten material, and supporting the members within the angle of repose. 7 8

Fusing materials, as in making borax glass. Leroy G. Black (to American Potash & Chemical Corp.). U. S. 2,177,766, Oct. 31. App. is described, and a method of producing fused material in particle form, which comprises subdividing a supply of such granular material into a shower of sepd. particles as the same enters a heating zone, permitting the material to fall through the heating zone and thence through the cooling zone, supplying heat to the particles as they are falling through the heating zone and cooling them while passing through the cooling zone, and maintaining a portion at least of the walls of the heating zone under exterior gas pressure sufficient to cause the flow of gas from the walls into the zone to prevent contact of the falling material with the walls. 9

Apparatus for feeding glass-making materials to a melting tank. Carl A. Brown and Charles W. Craig (to General Elec. Co.). U. S. 2,178,418, Oct. 31. Various structural, mech. and operative details. 1

Glass sheet. Pete Magrini (to American Window Glass Co.). Can. 384,676, Oct. 17, 1939. A sheet is continuously drawn from a bath of molten glass, a gas is circulated in contact with both faces of the sheet in the same direction transversely from one edge to the other edge adjacent to the meniscus, and after the sheet is set a gas cooler than the sheet is blown against at least one face. An app. is described. Cf. *C. A.* 33, 8946[4].

Apparatus for forming glass sheet. Joseph H. Lewis (to Blue Ridge Glass Corp.). Can. 384,852, Oct. 31, 1939. Structural details.

Tempering glass sheets. Geo. E. Howard (to Hartford-Empire Co.). U. S. 2,178,520, Oct. 31. App. is described, and a method of case-hardening a sheet of glass, which comprises heating the sheet to a temp. approx. its softening point and until the sheet is substantially free from strains, chilling the glass on opposite sides in predetd. areas opposite one another, and locally heating the glass internally in the areas at a rate higher than that of heating other areas of the sheet not chilled as aforesaid by dissipating electrical energy locally therein to modify the temp. differentials in the glass resulting from the cooling of the surfaces of the areas.

Forming glass building blocks. Randolph H. Barnard. U. S. 2,179,317, Nov. 7; Can. 385,798, Dec. 26, 1939. 4

Producing tubes of glass or the like and forming the tubing into coils. Theodor Pfaff (to General Elec. Co.). U. S. 2,177,743, Oct. 31. Various details of app. and operation suitable for gathering a parison of glass between a blowpipe and a gathering iron, drawing a length of tubing of the desired dimension from the parison and bending it into the desired form while it is still plastic.

Glass-coated screen. Jesse T. Littleton (to Corning Glass Works). Can. 384,878, Oct. 31, 1939. A screen suitable for filtering acids and similar corrosive materials is prepd. by submerging a metallic screen in a bath of molten glass, withdrawing the coated screen, draining surplus glass from the screen in a heated chamber, and opening the mesh by playing a flame on the screen.

Tempering glass articles. Jesse T. Littleton and Ralph K. Day (to Corning Glass Works). Can. 384,877, Oct. 31, 1939. To temper more highly the inner surface areas having smaller radii of curvature than the remaining surface areas, a heated glass article is supported in vertical position, filled by selectively directing chilling fluid against inner surfaces of the article, the container immersed in a bath of chilling fluid while being filled, and the movement of fluid into and out of the container continued for a fixed period after its immersion. An app. is described.

Cracking-off machine suitable for use in the manufacture of articles of glassware. Albert B. Knight. U. S. 2,177,807, Oct. 31. Various structural, mech. and operative details.

Multicellular glass. Sanford L. Willis (to Corning Glass Works). Can. 384,273, Sept. 26, 1939. A mass of glass particles is heated under both mech. and gaseous pressure progressively to sinter the particles and entrap interstitial gas, and a vent is maintained in one direction from the sintering zone through the mass for the escape of gas; expansion is effected in the unconsolidated mass. An app. is described.

Impervious clay pots resistant to acids and alkalies. Sándor Bleier. Hung. 121,783, Oct. 16, 1939. Clay is suspended in water, neutralized, dild. and sedimented. The pptd. layers are mixed in given ratios, ground to fine powder, neutralized and dried. Pots are made as usual and fired as biscuit ware. The surface is cleaned with a strong alkaline soln. and enamel, m. 600–850°, applied by galvanoplasty. A final enamel is applied and the pot fired in the usual manner.

Refractory articles from Siemens-Martin slag. N. A. Sperantov and M. A. Matveev. Russ. 51,765, Sept. 30, 1937. The ground slag is melted with Na_2CO_3 and sand in amts. assuring a total content of SiO_2 in the mixt. of 60–2%, formed into articles and heated to 900–50°.

Refractory bricks suitable for use in furnace construc-

tion. Gilbert E. Seil (to E. J. Lavino and Co.). U. S. 2,170,254, Aug. 22. A body such as a fire-clay brick is provided with a dried but unfired, waterproof and cementatory adhering coating including a water-insol. base, such as chrome ore and periclase. 1

Ceramic insulation for spark plugs. Taine G. McDougal, Albra H. Fessler and Helen B. Barlett (to General Motors Corp.). U. S. 2,177,943, Oct. 31. A dense, nonporous body consists of a sintered mixt. of corundum with 0.5–80% (suitably 3%) of Ta oxide. 2

Insulator for radio tubes. Russell E. Palmateer (to Hygrade Sylvania Corp.). U. S. 2,179,381, Nov. 7. A composite insulator member for radio tubes comprises a sheet of refractory elec. insulating material such as mica and a sep. coating thereon of a refractory material comprising a dried hydrolyzed metallic salt of high elec. insulating qualities, such as dried hydrolyzed Al nitrate, to improve the surface insulation characteristics of the member. 3

Abrasive wheels, etc., with a binder of synthetic resin. Samuel S. Kistler (to Norton Co.). U. S. reissue 21,252, Oct. 31. A reissue of original patent no. 2,150,121 (*C. A.* **33**, 4756²).

Abrasive articles. Samuel S. Kistler (to Norton Co.). Can. 384,156, Sept. 19, 1939. A mixt. of abrasive grain and a synthetic-resin bond is pressed in a mold, and the pressed mixt. cured in an autoclave under an abs. pressure of about 2 atm. to prevent the water formed in curing from passing into steam and swelling the abrasive article. Cf. *C. A.* **33**, 4756².

Abrasive articles such as grinding wheels. Samuel S. Kistler (to Norton Co.). U. S. 2,177,940, Oct. 31. Abrasive grains are united by a rubber bond contg. aniline-formaldehyde resin.

Enamel coatings on the interior of tubes of glass, etc. Wm. M. Clark and Charles D. Spencer (to General Elec. Co.). U. S. 2,178,419, Oct. 31. App. is described, and a method of coating a vitreous tube which comprises applying a layer of an enameling mixt. to the inner surface of the tube, placing the tube around and spaced from an elongated electrical heating element, rotating the tube about its longitudinal axis while passing a controlled elec. current through the heating element to bake the enameling mixt. at a relatively low temp., gradually increasing the current through the heating element until the softening temp. of the vitreous tube is approached and then maintaining the tube at this high temp. until the coating matures. Such a method is suitable for use in the treatment of elec. lamp tubes.

20—CEMENT AND OTHER BUILDING MATERIALS

J. C

Resistance of sulfur cements. C. R. Payne and W. W. Duecker. *Chem. & Met. Eng.* **46**, 766–70(1939).—The S cement described is composed of S 58.8, olefin polysulfide 1.2, crushed silica, graded 39.8 and C black 1.0%. Cement of this type has been successfully used in building metallurgical pickling tanks, dairy floors, and as resistant linings for acid and chem. storage tanks. Since S contracts about 12% upon solidification these cements are more or less porous. By proper manipulation the porosity can be reduced to 4%. S cement showed no corrosion when immersed in H_2O, 8 35% HCl, 15% HNO_3, 10–80% H_2SO_4 and H_3PO_4 for periods ranging from 24 to 52 weeks. Metallurgical pickling tanks constructed of brick jointed with S cement have withstood the action of all concns. of H_2SO_4 up to 65% for periods up to 8 years and showed no corrosion. From 30 to 56% HNO_3 and oleic acids are corrosive toward this cement, as is kerosene and other mineral and vegetable oils. Lime and a satd. soln. of an alk. cleaner show no corrosive action at room temp. but at 80° becomes corrosive toward the S cement. H. E. M. 5 6

Utilization of slags for the production of cement. A. Tysskiĭ. *Tsement* **1938**, No. 12, 12–15; *Khim. Referat. Zhur.* **2**, No. 4, 105–6(1939).—To increase the activity of blast-furnace slag it is recommended to add limestone and alumina to the molten liquid slag. This is best done in a mixing device into which the molten slag flows directly from the blast furnace. The temp. in the mixer is kept at a definite level to ensure a thorough mixing. The utilization of the waste blast-furnace gases lowers the cost and simplifies the construction of such an equipment. W. R. Henn 7

A study of pozzuolanas. Fernando Luiz Lobo Carneiro. *Ministerio trabalho ind. com., Inst. nacl. téc.* (Rio de Janeiro) **1939**, 3–34.—The crushing strength of a mixt. of 20 parts of pozzuolana and 80 parts of portland cement, figured on the strength of normal neat cement, increases from 65% on the 1st day to 102% on the 84th. Initial setting time is not changed. The 80–20 mixt. has satisfactory resistance to sulfate waters. Suggested specifications for the crushing strength of portland-pozzuolana cements for exposure to sulfate waters in kg. per sq. cm. are: 3rd day 60, 7th day 120, 28th day 220 and 84th day 300. Portland-pozzuolana mixts., with 1 exception, showed a considerably smaller coeff. of expansion than neat cement. O. W. Willcox 8 9

Effect of drying temperature on the activity of diatomite. S. M. Royak and A. T. Ivanova. *Vsesoyuz. Nauch.-Issledovatel. Inst. Tsement., Sbornik Rabot* **No. 18**, 3–14(1937).—The temp. of drying diatomite used in the production of pozzuolana portland cement does not affect the activity of this type of hydraulic admixts. when fired at temps. up to 700°. M. V. Condoide

Use of tripoli from Kuteĭnikovo and Kamenets-Podol'sk in the Ukraine for mortar and concrete. P. P. Budnikov and M. G. Sinyavskaya. *Trudy Khar'kov. Khim.-Tekhnol. Inst. S. M. Kirova* **1**, 89–96(in English, 96–7)(1939).—Kuteĭnikovo tripoli had 21.70% active silica and the Kamenets-Podol'sk type had 17.64%. Specimens prepd. from lime-tripoli mortars with slag had a higher mech. strength than those prepd. from lime-tripoli mortars with sand. The mech. strength of the specimens acquired after one month may be reached by steaming for 24 hrs. at 70°. The compns. of the tripoli, specimens and slag are listed. B. Z. Kamich

Impregnation of wood with wax materials and resins. Nowak. *Umschau* **43**, 840–2(1939).—Earlier work showed Bakelite resins penetrate poorly and render the wood brittle. The most recent developments involve the use of alkyd resin-montan wax mixts. in solns. of a solvent of high C, low b. p., good heat cond. and fireproofness such as trichloroethylene. The technique and the crit. factors involved in the impregnation of the wood and recovery of the solvent are briefly described. Impact, elasticity of compression, water content and water-absorption tests on impregnated red beech are graphically illustrated. H. Kwart

---

Adhesive portland cement. Lloyd L. Smith. Can. 384,525, Oct. 10, 1939. A quick-drying cement for application to dry surfaces is prepd. by dissolving 5 parts stearin in water, adding the soln. to 33 parts of lime under controlled steam pressure to hydrate and slack the lime, mixing the dry lime stearin powder with 72 parts casein, and mixing with 1750 parts portland cement.

Pitch compositions suitable for coating roads, use as a paint, etc. Wm. Zaisser (50% to Harry S. Walker). U. S. 2,178,770, Nov. 7. A dry compn. contains pitch together with a dry pulverulent aggregate to prevent coalescence of the pitch in storage, the pitch being so finely pulverized as to be quickly and completely sol. in a cold solvent to form a freely flowing easily brushable paint.

Fireproofing cellulose materials. Edwin C. Clayton and Lawrence L. Heffner (to Wm. E. Hooper & Sons Co.). U. S. 2,178,625, Nov. 7. Fibrous materials such as wood or cotton fabrics are treated with an aq. soln. of a fire-

retarding agent and a wetting agent, and the impregnated material is subsequently coated with material such as Zn borate, applied as a dispersion in a substantially 60% chlorinated paraffin oil or the like. 7

Fireproofing wood. William W. Bell (to Celluloid Corp.). Can. 384,554, Oct. 10, 1939. Wood or like material is impregnated with a water-sol. triaryl ester of H_3PO_4.

Impregnating timber. Tsentral'nyi Nauchno-Issledovatel'skii Lesokhimicheskii Institut "Tsnilkhi" (inventors, V. S. Klimenkov and I. V. Filipovich). Russ. 51,842, Sept. 30, 1937. Wood is treated with an acyl or an alkyl peroxide or hydroperoxide, as an accelerator of polymerization, and then impregnated with vapor or soln. of vinyl chloride, chloroprene, or similar deriv. of bivinyl, and the impregnating material is polymerized.

21—FUELS, GAS, TAR AND COKE

A. C. FIELDNER AND A. GEORGE STERN

Characteristics of Diesel fuels influencing power and economy. A. J. Blackwood and G. H. Cloud. *S. A. E. Journal* **46**, 49–53T(1940).—See *C. A.* **34**, 869[4]. H. A. Beatty 3

Physicochemical properties of gasoline, alcohol and benzene fuels and their mixtures. P. Ribagnac. *IIme Congr. mondiale pétrole* **3**, Sect. 4, 615–35(1937)(in French).—Test data assembled at the Bellevue Test Station (France) on the properties of various motor fuels are presented. The following properties of gasoline, alcs. and benzene fuels and their mixts. are discussed: heat of vaporization, f. p., vol. contraction, corrosivity, density, detonation, distn., gum deposition, water tolerance, *n*, inflammability, heat of combustion, stability, vapor tension, vapor lock, viscosity and volatility. Advantages and disadvantages of engine operation on either straight alc. or straight benzene or on mixts. of these with gasoline are enumerated. The ternary mixt. of alc.-gasoline-benzene is considered a good fuel because of the fact that the benzene acts in a three-fold manner, viz., to provide water stability, increase the heat of combustion and to increase the octane rating. In a 70-15-15 mixt. of MeOH, EtOH and benzene the EtOH supplies the calorific deficiency of the MeOH and also lessens the tendency to self-ignition. E. J. Mahler 4 5

Engine fuel testing and proposals for its further development. A. v. Philippovich. *Natl. Petroleum News* **31**, R-526–40(1939).—The disadvantages of present octane no. detns. include (1) the conditions are set to give a mean value applicable to road tests, (2) use of a single air-fuel ratio and mixt. temp., and (3) defects in the bouncing-pin method. A new knock-indicating instrument should be developed. C. H. Brooks 6

Use of gum inhibitors in refining of motor fuels. W. W. Scheumann. *Oil Gas J.* **38**, No. 25, 41, 42; *Refiner Natural Gasoline Mfr.* **18**, 518–20(1939).—A review, giving reasons for use, types, requirement, cost data and a typical flow sheet. W. Andrew Wright 7

Determination of richness of fuel by exhaust-gas analysis. H. Moynot. *IIme Congr. mondiale pétrole* **3**, Sect. 4, 599–603(1937)(in French).—Based on the relationship between the H and CH_4 content of exhaust gases and the richness of the gasoline mixt. an assumption is made that an analysis of the exhaust gases is the key to an indication of the richness of the gasoline mixt. and a measure of control of the richness of different gasoline mixts. Examples are given of calcns. showing the amt. of gasoline converted to methane for rich and lean mixts. E. J. Mahler 8

Wood waste for fuel. I. Preparation of hog fuel. J. E. Hyler. *Southern Power and Ind.* **58**, No. 1, 57–9(1940).—When a market is available for sawdust, it is preferable to reduce the wood waste to that form. If not, wood waste can be satisfactorily fired alone, or in combination with coal, but it is desirable to reduce the wood to a uniform size suitable for handling by a pneumatic conveyer or the so-called blower system. Heavy pieces tend to smother the fire. Refuse hogs are very rugged and modern forms stand up well, especially the swing-type with sharp pointed hammers. Difficulties are discussed as well as maintenance problems. R. W. Ryan 9

By-product fuels in the steel industry. E. G. Fox and W. B. Clemmitt. *Trans. Am. Soc. Mech. Engrs.* **61**, 665–72(1939).—Coke-oven gas, blast-furnace gas and their mixts. are used for underfiring coke ovens, and for blast-furnace stoves, open-hearth furnaces, soaking pits and heating furnaces, annealing and heat-treating furnaces, boilers and gas engines. The economics of the use of mixed gases is discussed. George Ayers 10

Mechanism of formation of oxides of nitrogen in the explosion of combustible fuel mixtures. A. G. El'kenbard, R. I. Genkina and M. V. Polyakov. *J. Phys. Chem.* (U. S. S. R.) **13**, 464–72(1939).—Mixts. of CH_4-N_2-O_2 and CO-N_2-O_2 were exploded in glass vessels and the gaseous products analyzed. The amts. of NO formed are shown in 7 figures as functions of the exptl. conditions. The max. amts. of NO are obtained for an O_2/CH_4 ratio of 3, and a diam. of 100 mm. For the CO combustion, the max. NO concn. is obtained for $O_2/CO = 1.5$ at 40 mm., 2.0 at 85, 2.3 at 105, and more than 3 at 142 mm. pressure. The max. amt. of NO obtained in any case was 1.6%. F. H. Rathmann

Catalytic dehydrogenation of gaseous paraffins. Aristid V. Grosse and V. N. Ipatieff. *Ind. Eng. Chem.* **32**, 268–72 (1940); cf. following abstr.—Catalysts for the rapid and highly selective dehydrogenation of ethane, propane and the butanes to the corresponding olefins are prepd., for example, by satn. of activated alumina with an aq. chromic soln. giving less than 10 mole percent CrO_3 after drying and heating. H. A. Beatty

The catalytic dehydrogenation process (gaseous paraffins to olefins). A. V. Grosse, V. N. Ipatieff, Gustav Egloff and J. C. Morrell. *Refiner Natural Gasoline Mfr.* **18**, 478–85(1939); *Natl. Petr. News* **31**, R-520–1(1939); cf. preceding abstr.—Cr_2O_3-on-Al_2O_3 catalyst is used selectively to dehydrogenate iso-C_4H_{10} or C_4H_{10} and their mixts. The catalyst is regenerated by controlled combustion. The process operates at 1050°F. and slight pressure. The products are sepd. by conventional fractionation. The concn. of olefin in the product gas is several times higher, and the capacity of the equipment many times greater, than for thermal dehydrogenation. 4 references. C. H. Brooks

Low-temperature carbonization. Narrow brick retorts at the Fuel Research Station. II. J. Fraser Shaw. *Dept. Sci. Ind. Research* (Brit.), *Fuel Research, Tech. Paper* No. 50, 29 pp.(1939); cf. *C. A.* **27**, 3313.—An account of the experience with, certain details of setting and operation, and some improvements in the design of vertical continuously operating retorts. Fifty-seven different coals, covering a wide range of caking properties, volatile matter and sizes of charging were carbonized. The following broad generalizations were derived: (1) Cokes derived from noncaking and medium-caking coals are more combustible than those from strongly caking coals. (2) The size of coal carbonized has a marked effect on the throughput (rate at which charge travels through retort) and on the yield and nature of the tar produced. Increase of particle size permits an increased throughput and is accompanied by increased yield of tar of lower sp. gr. Special studies were made on retort wall temps., preferential combustion processes, etc. The com. setting of several low-temp. brick retorts is described and the yields are discussed. I. Hartmann

Crystallite growth during carbonization. H. E. Blayden, H. L. Riley and A. Taylor. *J. Am. Chem. Soc.* **62**, 180–96(1940); cf. *C. A.* **33**, 7521[8].—The investigations of crystallite growth during carbonization in the

temp. range 400–1300° have been extended to include 1 American and 2 Welsh anthracites, lignin and an Irish peat, and carbonization temps. up to 2200°. The anthracite crystallites show a decrease in the *c* dimensions as the carbonization temp. is increased from 400 to 900°. This has been interpreted as due to disruption of the crystallites. The peat coke crystallites show a very rapid growth in the *c* direction between 700 and 1000° which is probably due to a catalytic effect. A. B. Garrett

Coal situation and outlook. Jesse V. Sullivan. *Mfrs. Record* **109**, No. 1, 36, 72(1940).—Descriptive. L. S.

The chemist in the coal bin. Charles M. Hackett. *Mining Congr. J.* **25**, No. 11, 22–4(1939).—A review of various developments in chem. research which hold promise of expanding the uses of coal as a raw material in such chem. industries as artificial rubber, coal-tar products, various "crudes" or intermediates, drugs and serums. Leopold Scheflan

A formula for calculation of the calorific value of coal from chemical analysis. László Simegi. *Magyar Mérnok Épitészegylet Kozlonye* **73**, 345–6(1939).—Recent coals contain more carboxyl and fewer carbonyl groups than do older ones. The new formula was developed on the assumption that half of the O contained by the coals is present as water of hydration and half as carbonyl. The formula for the upper calorific value is: 81 [C − (O/2) 0.75] + 345 [H − (O/2) 0.125] + 25 S. The lower calorific value is calcd. by: 81 [C − (O/2) 0.75] + 285 [H − (O/2) 0.125] + 25 S − $6H_2O$. In very recent coals (lignites) the formula, like all other formulas, does not give quite reliable data. S. S. de Finály

A study of the equilibration method of determining moisture in coal for classification by rank. O. W. Rees, F. H. Reed and G. W. Land. *Illinois State Geol. Survey, Rept. Investigations* No. **58**, 34 pp.(1939).—The equilibration method first proposed by Stansfield and Gilbart (*C. A.* **27**, 4373) attempts to det. the moisture in coal at 100% humidity, which is assumed to be the true bed moisture. In this paper are presented the results obtained by applying this procedure to 21 Illinois coals, ranging in moisture content from 4 to 18%, as well as data obtained by other procedures, with which comparisons are made. Six of the coals were tested by the procedure and equipment similar to that described by Stansfield and Gilbart; a large air oven to provide const. temp. was used. The discrepancies in the results indicated inadequate temp. control. Therefore a const.-temp. water bath was substituted for the air oven and equilibrations of 15 other coals were made. In addn., equilibration tests were made at 3 or 4 humidities on these 15 samples; a N atm. without evacuation of the desiccators was used. The study led to the following conclusions: (1) The equilibration procedure as applied to Illinois coals studied produces data which, when plotted, give irregular moisture-humidity curves. Satisfactory extrapolation of these curves to give 100% humidity-moisture values is impossible. (2) Low and medium humidity values do not appear to affect the slope of the extrapolated curves. (3) Other procedures which are much simpler, but may involve slight modification of the standard procedure for sampling, appear to produce results suitable for classification by rank. (4) The general equilibration method may be useful for studying the nature of the moisture in coal. The vapor pressures of the saturated salt solutions used in equilibration tests were detd. by the static method used by Frowein employing an oil-filled siphon manometer, and by the Rayleigh manometer method for the measurement of low pressures. The latter procedure with certain modifications was found satisfactory. I. Hartmann

Briquetting of Chelyabinsk and Moscow soft coals. N. P. Chizhevskiĭ and P. I. Neverov. *Sovet. Met.* **1938**, No. 3, 7–13; *Khim. Referat. Zhur.* **2**, No. 4, 112–13(1939).—The object of the expts. was to obtain soft-coal briquets suitable for the blast-furnace process and for gasification in powerful generators. Besides the Chelyabinsk and the Moscow coals, mixts. of the Chelyabinsk with the Kizelov coal and of the Moscow with the Don coal PZh were investigated. Pressure, moisture content in the initial mixts., and the temp. of the molds and of the coals were measured. The content of moisture, ash, S and volatile substances were also measured in coals and in coke-briquets. Compn. of gases (obtained during the coking of the briquets in Bauer's app.), abrasive properties, resistance to crushing and drop tests were studied. The Chelyabinsk coal did not produce satisfactory briquets. Addn. of 25–35% of Kizelov coals, heating the mixt. to 70–80° and the molds to 90–100°, a moisture content of 12–15% and a pressure not less than 1200 kg./sq. cm. produced briquets suitable for industrial purposes. Addn. of resin increased the resistance to moisture and to abrasion. The Moscow coal produced strong, but thermally unstable briquets, which were also unstable to the action of water. Good briquets were obtained by addn. of 15–20% of the PZh Don coal under a pressure of 900–1200 kg./sq. cm., with a moisture content of 10–15%, and the temp. of the mixt. of 70–80° and of the molds of 90–100°. An addn. of 2–3% of resin lowered the hygroscopicity. The content of the Don coal in the mixt. can be reduced to 15%. The briquets were suitable for gasification in powerful generators. W. R. Henn

Treatment of coal at medium temperatures. N. A. Nikol'skiĭ and M. A. Stepanenko. *Coke and Chem.* (U. S. S. R.) **1938**, No. 12, 11–12; *Khim. Referat. Zhur.* **2**, No. 4, 113–14(1939).—The mixt. (which is coked at 600–800°) contains 20–5% of volatile substances and 7% of ash. When a larger amt. of ash is present the coal is enriched by the wet method and dried. After its removal from the furnace the coke is mixed with water. The "fixed carbon" contains moisture 2%, volatile substances 8–12% and ash 9–10% and has a heat content of 7200–7300 cal. From the treatment of the coal a tar is obtained which contains 35–45% of phenols in oils from which C_6H_5OH and *o*-, *m*- and *p*-$CH_3C_6H_4OH$ can be obtained. Treatment of gas coals yields up to 8.5% of tar, of which 1.0–1.1% is motor fuel and 2% is Diesel engine fuel. W. R. Henn

The effect of preparation on ash fusibility as revealed by a study of selected Illinois coals. L. C. McCabe and O. W. Rees. *Trans. Am. Soc. Mech. Engrs.* **61**, 693–8(1939); *Illinois State Geol. Survey, Rept. Investigations* No. **55**, 31 pp.(1939).—Based on work with 10 coal samples from different counties in Illinois, sizing indicates 4 different groups within which the ash-fusion relationships are similar. No similar groupings can be made from results of cumulative sp. gr. sepns., with possible exception of coals from St. Clair and Marion counties. The effect of combining portions of narrow sp. gr. range is to lower high ash-softening temps. and to raise low ash-softening temps. of the component portions. The greatest difference in ash-softening temp. was obtained with sized coals of narrow sp. gr. ranges. George Ayers

Determination, causes and significance of the ion content of air in mines. Ludger Funder. *Gerlands Beitr. Geophys.* **54**, 370–449(1939).—The content of small and large ions in the air within mines (coal, potash and ore) was studied. The ion content of the coal mines of Westphalia and the potash mines of Hanover is about that of the free atm.; but in the Harz Pb-Zn mines it is 10–30 times higher. The ionizing action of the different types of rocks is described in detail. The age of the mine and depth of the rocks have no influence. In coal mines, because of the low elec. cond. of the air, high electrostatic charges may result on the conduits for compressed air, causing discharge sparks which may ignite choke damps. J. F. Schairer

The underground gasification of coal. A. B. Chernyshev. *Vestnik Akad. Nauk S. S. S. R.* **1938**, No. 9–10, 44–9; *Khim. Referat. Zhur.* **2**, No. 4, 113(1939).—Failure of the first expts. is attributed to improper preliminary crushing of the coal. The following method (the "current" method) was found to be very effective. Two sloping excavations are made around the coal deposit, parallel to each other and connected by means of a horizontal excavation (the "fire shaft"). Through one of the sloping excavations a blast is directed into the "fire shaft," while the gas formed escapes through the other. A no. of unsolved questions are discussed. W. R. Henn

Principles of underground gasification [of coal]. S. I. Buyalov. *Ugol* **1938**, No. 11, 17–24; *Khim. Referat. Zhur.* **2**, No. 4, 113(1939).—A short description of the principles of underground gasification of coal. The "current" generator method of gasification can be used for steep, small deposits which have a thermally stable roof. The interlayer "pit hole" method can be used for large deposits and for deposits which have a porous roof. In the "current" method the blast is directed through a shaft. Owing to the high temp. of the process (up to 2000°) the periodic blowing for coals having a low-melting ash (below 1300°) is impracticable because a closing up of the "fire shaft" by the formed slag is possible. The inter-layer gasification is obtained by drilling holes 100 mm. in diam. at the bottom of the deposit. The coal is electrically fired through the holes. A hermetically sealed system is necessary to ensure the success of the underground gasification. A gas of heating value 1100–1300 cal. per cu. m. was obtained, at a cost for the Donbass region of 0.15–0.4 kopeks/1000 cal. W. R. Henn

Underground gasification of coal in the Moscow region. N. V. Lavrov, I. L. Farberov and R. N. Pitin. *Vestnik Inzhenerov i Tekh.* **1939**, No. 10, 423–4.—A method is described for the underground gasification of coal deposits near Moscow. The coals have a higher activity and ignitability than anthracite coals. Upon being heated the coals do not pass through the plastic state but their porosity increases sharply. When gasification is conducted below the fusion point of the ash the latter forms a highly porous structure which retains approx. the original form of the coal. B. Z. Kamich

Production and use of montan wax from Ukrainian brown coals. I. A. Rapoport and I. E. Nefmark. *Koshevenno Obuvnaya Prom. S. S. S. R.* **1939**, No. 8, 17–20.—A review. At present the manuf. of crude montan wax is well under way. Lab. expts. on refining the crude wax have been satisfactory, the yields were as high as 45–55% and the quality of the wax is claimed to be as good as the imported carnauba wax. Twenty-eight references. B. Z. Kamich

Influence of richness of fuel on the energy balance of combustion engines. Louis Thaler. *IIme Congr. mondiale pétrole* **3**, Sect. 4, 604–10(1937)(in French).—Results of a study of the relationship between the energy release in combustion engines and the richness of the fuel mixt. are presented. Exhaust gases were analyzed to det. the amt. of waste energy. The energy balance is thus calcd. for a 4-cylinder automobile engine, an air-cooled aviation engine and a 2-cylinder Diesel motor. E. J. Mahler

Gasoline engine combustion. Hector Rabezzana, Stephen Kalmar and Alfred Candelise. *Automotive Ind.* 81, 534–42, 632–9(1939).—Small vol. increments burn at const. vol., then expand into both the previously burnt and the still unburnt portion of the mixt. until pressure equil. is reached. As the reaction progresses, each increment burns under different conditions of pressure, temp. and chamber vol. The time elapsed for a given linear flame displacement in space is detd. by the linear rate at which the flame travels with respect to the unburnt gas. A method for predetg. pressure-time characteristics of a chamber design is presented. The duration of the entire combustion cycle, depending chiefly on the reaction velocity, controls the peak pressure and also detonation. Consequently, for given fuel-air mixts. there is a definite relation between the max. pressure that can be obtained without detonation and the corresponding time elapsed from ignition. The initial stage of combustion is the most sensitive to the effect of the various factors governing the reaction velocity. Leopold Scheflan

Thermochemical conditions for the transformation of energy in combustion engines. Andre Mandel. *IIme Congr. mondiale pétrole* **3**, Sect. 4, 611–14(1937)(in French).—In a discussion of the factors governing the functioning of internal-combustion engine, and of the factors responsible for the conversion of the fuel elements into power, the heat and chem. changes are considered of paramount importance. The prepn. of the air and the fuel and its movement within the chamber are discussed as is the discharge of heat energy after combustion. E. J. Mahler

Combustion engine exhaust pressure. R. Guyot. *IIme Congr. mondiale pétrole* **3**, Sect. 4, 595–8(1937)(in French).—From a study of the relationship between exhaust pressures, temp. variations, inlet pressure and consumption of motor fuel in combustion engines, and with the aid of curves, G. proposes a method for the detn. of the correct air-fuel ratio for the optimum performance of a given engine under various atm. conditions. E. J. M.

Darkening (blackout) of gas and water works by the luminescent method. Nikolaus Riehl and Ernst A. Fick. *Gas- u. Wasserfach* **82**, 781–3(1939).—Paints and plastic strips capable of luminescence in ultraviolet light are affixed to valves, gages, stairs, pillars, etc., of gas and water works subject to air raids so as to facilitate operation without light visible to the fliers. These materials are illuminated by ultraviolet light from black or blue incandescent lamps of 80 or 120 w. size or by a recently developed low-current "blue-surface glow lamp." Both the ordinary incandescent lamp and the ultraviolet source are enclosed in gas-tight globes. The relatively small no. of gages and indicators in a gas or water works are easily fitted with special luminescent scales; the much larger no. of gages in an elec. plant must be removed and treated individually. The luminescent materials glow for a time after the ultraviolet source is shut off, giving a factor of safety. The operating facility of darkened plants using the luminescent materials has been much greater than anticipated, as the eye quickly adjusts itself to the low light intensity. R. W. Ryan

Standards for gas quality. F. Stief. *Gas- u. Wasserfach* **82**, 745(1939).—The following recommendations as to manufd. gas quality were made by the German Assocn. of Gas and Water Technologists: *Combustion characteristics.*—(1) The gross heat of combustion should be between 4200 and 4600 kg.-cal. per cu. m. (0°, 760 mm. Hg, dry) (corresponding to 440–482 B. t. u. per cu. ft.). The upper limit applies to coal (coke oven) gas and the lower to mixed coal and water gas. Variations in heating value at a given point should not exceed 1%, while a difference of not more than 50 kg.-cal. is permissible between the works and the consumer. (2) The density should be within the limits 0.4 to 0.5 (referred to air), the lower value applying to coal gas and the higher to mixed gas. Variations should not exceed ±3%. (3) Gas pressure should not be less than 60 mm. water column at any point. (4) Present methods of measuring ignition velocity do not give exact results but the flicker point on the Ott burner should be between 60 and 100, and on the "Test" burner, between 65 and 120, the lower limit applying to mixed gas and upper to coal gas. *Purity.*—The O content should be under 0.5%—preferably under 0.3% by vol. (2) H_2S should be under 2 g. per 100 cu. m. (the Pb acetate test is sensitive to 0.2 g. per 100 cu. m.). (3) NH_3 should be under 0.3 g. per 100 cu. m. (4) The permissible amt. of naphthalene varies with the temp. and can be calcd. by the formula: $\frac{5 \text{ to } 10}{p}$ = g. per 100 cu. m., in which p = pressure in atm. (5) Org. S should not exceed 25 g. per 100 cu. m.; cyanogen 15 g. per 100 cu. m. and NO around 0.2 cm. per cu. m. (6) The gas should be substantially free from tar. Various methods of "fine" purification are listed. R. W. R.

Discussion of standards for gas quality. Karl Bunte and Fritz Schuster. *Gas- u. Wasserfach* **82**, 745–8(1939).—The gas standards given in the preceding abstract are recommendations rather than legal standards. New developments have caused widening of permissible heating value limits. The reasons for establishing the various limits are given. As to purity, practical experience has indicated the practical possibility of reducing oxygen in the purified gas to 0.2 to 0.3%. The gas leaving the purifiers should be free from H_2S; the amount given in the standards takes into account the possibility of reforming H_2S in the distribution system. "Fine" purification methods offer the possibility of reducing organic S, H_2O, O

and NO considerably below the limits given. 16 references are given. R. W. Ryan

Combustion of gases. Karl Bunte, Horst Brückner and Gustav Choulat. *Gas- u. Wasserfach* 82, 763–5(1939).—An investigation of the compn. of the (intermediate) gas in the inner cone of the Bunsen burner showed that when the gas content was in excess of the theoretical amt. of O for complete combustion, the hydrocarbons were largely converted into CO and H, gases ready for combustion. However, traces of CH_4 are normally present in the intermediate gases from a normal manufd. gas, the fraction increasing with decreasing primary air in the fuel gas-air mixt. When gas from a detoxification plant, contg. all of the CO_2 formed, is burned in the same way, no CH_4 is found in the intermediate gas; this is attributed to the reaction of CO_2 and CH_4 to form CO and H. Hence the CO_2 favors hydrocarbon decompn. Only small amts. of O can exist along with combustibles in the intermediate gas; with an air-gas ratio of 1.03 combustion is complete. The CO content of the intermediate gas is less dependent on the initial CO content than on the total quantity of C-contg. gases. In CO-free gas, CO is formed in the inner cone by the water-gas equil. In the combustion of higher hydrocarbons, unsatd. hydrocarbons are found in the intermediate gas—when these unsatd. hydrocarbons are present in even very small amts. they assist in the formation of after-luminescence (aureole) of the flame. R. W. R.

Mixing gases in porous media. Richard Drucker and R. L. Huntington. *Oil Gas J.* 38, No. 34, 37–41(1940).—Gas recycling and pressure-maintenance are used in some producing fields to conserve gas, maintain reservoir conditions and improve production. The object of this paper is a study of the amt. and flow rate of dry gas necessary for optimum results. Lab. wells were used and data taken by analysis of gas and air mixts. Graphical data indicate that Fick's law of diffusion is not followed. Curves are given on single and three-dimensional flow. Until a mass of data has been taken on injection rates, well spacing, gas densities, permeability and porosity, an empirical attack is the only approach to a problem of such importance to field life from the viewpoint of dilu. of rich distillate gas with dry recycle gas. W. Andrew Wright

Secondary gas in the Donbass region. I. M. Pechuk. *Ugol* 1938, No. 11, 63–4; *Khim. Referat. Zhur.* 2, No. 4, 115(1939).—Cases of a violent escape of natural gas during drilling operations near the Kremennaya coal shaft in the Lisichansk region are described. In one case the initial yield of gas was 9000 cu. m./day with a pressure of 13 atm. The gas contained 96% of CH_4 and considerable He. The origin of the gas and of the salt solns. has not been detd., but it is not due to desorption of the coal of the Lisichansk region. W. R. Henn

Radiation of flue gases. A. Schack. *Arch. Eisenhüttenw.* 13, 241–8(1939).—In a specially developed app. the flue gas is passed through a cylindrical heat-resisting steel vessel which can be heated electrically. Formulas were derived of sufficient accuracy for the radiation above 450°. For CO_2, the formula is $q = 3.5\ (ps)^{1/3}(T/100)^{3.5}$ kg.-cal./m.² hr., for water vapor $q = 35\ p^{0.8}\ s^{0.6}(T/100)^3$ kg.-cal./m.² hr. T is abs. temp., p the partial pressure in atm. of the gas, s the thickness of the gas layer in m. The heat transmitted from or to the gas for CO_2 is $\alpha = S(ps)^{1/3}[0.0513(t_g + t_w) - 30.25]$ kg.-cal./m.² hr. degree, for water vapor $\alpha = Sp^{0.8}\ s^{0.6}[0.107(t_g + t_w) - 46.5]$ kg.-cal./m.² hr. degree, where p is partial pressure of radiating gas in atm., s as before, t_g gas temp., t_w temp. of area or surface radiated, S the degree of blackness of the radiated surface for infrared radiation (between 0 and 1; 1 = black body). The radiation of nonluminescent flames is the same as the radiation of CO_2 and H_2O, under same conditions, after completed reaction; the flame reaction does not increase the total radiation. Among other gases, hydrocarbons have a considerable radiation, CO has little, O and N have none. The heat transmission of a gas contg. little CO_2 and much H_2O is considerably better than that of a flue gas with much CO_2 and little H_2O. The radiation of gas bodies of different shapes (cylinder, between plates, sphere, etc.) is calcd.; the thickness of layer thus detd. can be used in the radiation formulas. M. Hartenheim

Determination of the yield of coke gas and of the amount of heat needed for coking. B. I. Kustov. *Coke and Chem.* (U. S. S. R.) 1938, No. 14, 38–40; *Khim. Referat. Zhur.* 2, No. 4, 114–15(1939).—Total amt. of gas used should be detd. by a measuring app. connected to the system after the benzene scrubbers. This permits control of the yield of the chem. products. The amt. of heat used in coking can be detd. from the formula adopted by the committee of the Essen Mining Industry. For the moist mixt. $q_b = V_0Q_H/G_b$, where V_0 is the amt. of gas in cu. m. which is supplied for the heating of the oven per unit of time, Q_H is the no. of cal./cu. m. of the gas, G_b is the charge of the moist mixt. for the same period of time. For the dry mixt. $q_c = (q_b - 12W)/(100 - W)$, where W is the percentage of moisture in the mixt.; 12 cal. is the approx. amt. of heat used for the evapn. of 1% of moisture in the mixt. W. R. Henn

Gas detoxification at Vienna-Leopoldau. H. C. Gerdes. *Gas- u. Wasserfach* 82, 774–5(1939).—Polemical with Marischka (cf. *C. A.* 33, 6563[1]). Steam requirements for the Bössner-Marischka process were calcd. as 0.13 kg. per cu. m. of the treated gas (0°, 760 mm. Hg., and dry) as compared with 0.49 kg. for the Ges. für Gasentgiftung (Hameln) process, both calcns. being made for the same initial gas with a final CO content of 1%. This is much lower than the ratio of 1:20 given by Marischka. Very large amts. of heat are required in the B.-M. process to drive off CO_2 from the catalyst; and if this is calcd. in terms of steam, total steam requirements would be 1.89 kg. as compared with 0.49 for the Hameln process. The price given for the ankerite catalyst is too low to include any prepn. cost. **Reply.** Carl Marischka. *Ibid.* 775–6.—The Bössner-Marischka process will give a gas of much lower than 1.0% CO content, and has a very large advantage in lower steam consumption as compared with the Hemeln process. The 1:20 ratio between the 2 processes was the result of actual calcns. This high steam cost is an important factor. Gerdes gives much too high figures for the heat required for regenerating the catalyst, and it should be possible to realize a much higher recovery. Furthermore, a continuous circulation of the catalyst through the gas and regeneration stages is used. The ankerite is used in the form in which it occurs naturally. **Reply.** Gerdes. *Ibid.* 776–8.—New calcns. have been made for the total steam requirements of the B.-M. and Hameln processes for final CO contents of 1% and lower, showing that this varies from approx. 2 for 1% CO to approx. 8 for gas with a final CO content of 0.1%. Calcns. as to heat requirements for catalyst regeneration were based on practical experience. The steam generated in the waste heat boiler would be in excess of total plant requirements. The low catalyst price would be more than offset by the addnl. heat required for catalyst regeneration. More exptl. data relative to the B.-M. process would be desirable. **Reply.** Marischka. *Ibid.* 778.—Owing to the pressure of other work it is impossible to make a thorough study of Gerdes' calcns. or publish addnl. exptl. results. The fact remains that the B.-M. process can give a nonpoisonous gas contg. only 0.3% CO. This has been proved in practice. R. W. Ryan

The mechanism of the synthesis of hydrocarbons from water gas. S. R. Craxford and Eric K. Rideal. *J. Chem. Soc.* 1939, 1604–14.—Expts. on the rates of formation and reduction of Co_2C on cobalt-thoria-kieselguhr catalysts under various conditions indicate that the first step in the Fischer-Tropsch synthesis of hydrocarbons from CO and H_2 is the reaction of these gases with the catalyst to give Co carbide. As indicated by the ortho-para hydrogen conversion, when the carbide is reduced only CH_4 is formed and no higher hydrocarbons. Reduction by H_2 leads to formation of oils. Curves are given for the rates of the reactions between Co and CO and between Co_2C and H_2 on the Fischer catalyst and also for the energies of activation of the reaction $Co_2C + 2H_2$ and for the total reaction $CO + 2H_2$. It is concluded that in order to obtain

oils the conditions of the synthesis have to be adjusted so that only very few chemisorbed H atoms are present on the catalyst surface. H. C. Thomas

Cost of hydrogen sulfide removal from refinery and sour natural gases. Basil Storrs. *Oil Gas J.* **38**, No. 23, 69, 70 (1939).—See *C. A.* **33**, 9594[8]. W. Andrew Wright

Improvements in the production of ammonia. Sh. M. Levin. *Coke and Chem.* (U. S. S. R.) **1938**, No. 11, 48; *Khim. Referat. Zhur.* **2**, No. 4, 116(1939).—The cost of steam is the main expense item in the production of concd. NH_4OH (30 tons of steam per ton of 100% NH_3). About $^1/_3$ of this amt. is used for the evapn. of the water. L. recommends increasing the no. of fixing plates without reducing the no. of the other plates. A saving of steam up to 5 tons per ton of NH_3 is possible. W. R. Henn

Production of two grades of crude benzene. G. N. Tyutyunnikov. *Coke and Chem.* (U. S. S. R.) **1938**, No. 10, 39–41; *Khim. Referat. Zhur.* **2**, No. 4, 115–16(1939).— On the basis of expts. performed under plant conditions T. recommends a no. of improvements in the production of benzene, mainly the construction of addnl. cooling app. and separators. Two grades of benzene can be successfully obtained. The amt. of the first grade can be increased to 50% of the total amt. of benzene distg. up to 180° if it is directly rectified after washing. The second grade is subjected to a preliminary rectification, then washed and again rectified. Such a system produces considerable saving in steam, decreases the loss of the product by 50% and makes the process more nearly continuous. By introducing only one powerful addnl. condenser in the Staro-Makeev plant the yield of first-grade benzene was increased to 38% (of the total amt. of crude benzene); it could be easily purified. W. R. Henn

Cleaning the benzene scrubbers with steam. A. S. Terent'ev and Ya. B. Chertkov. *Coke and Chem.* (U. S. S. R.) **1938**, No. 11, 47; *Khim. Referat. Zhur.* **2**, No. 4, 115(1939).—Results of cleaning the scrubbers with steam in the Staro-Makeev coke-chem. plant are given. Remove the oil from the scrubber, leave an opening of approx. 2 in. in the cover to create a partial vacuum, connect the scrubbers with a common collector for draining oil and condensate and force steam for 18–20 hrs. under a pressure of 5 atm. at 170° through 2-in. pipes. Up to 50 tons of steam is used per scrubber. The condensate seps. easily into layers without addnl. steam. The upper layer of oil is reused. Steaming is recommended twice a year. W. R. Henn

Errors in the method for the calculation of the yield of crude benzene to 180°. G. N. Tyutyunnikov and D. P. Dubrovskaya. *Coke and Chem.* (U. S. S. R.) **1938**, No. 11, 47–8; *Khim. Referat. Zhur.* **2**, No. 4, 115(1939).—The usual method for the calcn. of the yield of crude benzene by the lab. detn. of the amt. of the distillate to 180° gives high results, owing to the wrong recalcn. of the vol. units to the wt. units. Deviations from the true values amount to 3% when coal-tar oil is used, and to 0.5–1.0% with solar absorption oil. W. R. Henn

Extraction of fluorene from coal tar. P. P. Karpukhin and P. I. Mikhaĭlenko. *Trudy Khar'kov. Khim.-Tekhnol. Inst S. M. Kirova* **1**, 19–32(in English, 32–3)(1939).—Fluorene was extd. from coal-tar fractions 290–300°, 292–302°, 278–292° by use of the solvents ligroin, benzine, alc., and acetone. A yield of 67.5% pure fluorene was obtained from the fraction 290–300°, the solvents ligroin and benzine being about equally efficient. The fraction 292–300° yielded 53% pure fluorene after 3 crystns. from benzine. The fraction 278–292° contained large amts. of diphenylene oxide and was not suitable for fluorene extn. The results are tabulated. B. Z. Kamich

Adaptation of the periodic tar-distillation apparatus to the continuous process. A. G. Borts and G. G. Vodnev. *Coke and Chem.* (U. S. S. R.) **1938**, No. 11, 45–6; *Khim. Referat. Zhur.* **2**, No. 4, 114(1939).—At the Sergon coke plant, a tube still was constructed (replacing the individual stills) for the removal of water from tar. On passing from the storage tank through the tube still, the tar is heated to 170–80° and passed into the evaporator, where it loses water and the light-oil fractions. The mixt. of water vapor and oil is condensed and sepd. The dehydrated tar flows into a horizontal still which is under a pressure of 500–50 mm Hg, where it is distributed along 2 trays situated along the heated tubes. The vapors from the still pass through 3 dephlegmating columns. The pitch is removed from the vacuum still through an intermediate vessel connected with the still and with another vessel through which the pitch flows at the level of the heated tubes into the heat exchanger. Ways for improving this preliminary scheme of tar distn. are discussed. W. R. Henn

Electroplating with lead and chromium of metallic parts used in the coking industry. V. M. Kupchin. *Coke and Chem.* (U. S. S. R.) **1938**, No. 12, 46–8; *Khim. Referat. Zhur.* **2**, No. 4, 99–100(1939).—Electroplating with Pb and Cr to prevent corrosion was found effective. Fe parts were lead-plated from a soln. of Pb *m*-benzenedisulfonate (111 g./l.) and free *m*-benzenedisulfonic acid (30 g./l.) with a c.d. of 200–300 amp. per sq. m. The Pb-plated articles could be flattened, bent and sawed without sepg. the Pb coating. Under conditions of extreme corrosion (pipes in a condenser of NH_3 vapors) a protective layer of Pb 0.5–1.0 mm. thick is necessary. A 0.01–0.1-mm. layer of Pb is sufficient for atm. or gas corrosion. In their corrosion resistance the Pb-plated metal is equal to rolled and cast Pb and it is considerably more economical. The Cr platings are sufficiently resistant to corrosion in the atm. of the coke plants. Solid chromium surfacing is important for parts which are subjected to wear under conditions of little corrosion (rods of the hydraulic pump). W. R Henn

Ni steel and hydrogenation of fuels (Berthelot) 9. Ni alloys in mining and utilizing coal (Niwa) 9. Gas industry and Ni alloys (Tomita) 9.

Motor fuel. James W. Jean. U. S. 2,179,151, Nov. 7. A fuel is obtained by fermentation and distn. of various materials and contains BuOH 38, EtOH 10, acetone 30, turpentine 4 and benzene 18 parts.

Diesel fuel. Ernest F. Pevere and Wilfred N. Meyer (to The Texas Co.). U. S. 2,178,327, Oct. 31. About 1–5% of dipropionyl peroxide is added to improve the ignition characteristics of the fuel.

Binder for coal briquets. Lajos Kováts. Hung. 121,424, Sept. 1, 1939. Seeds of lupines or soybeans are steeped in an acid soln. for 8–12 hrs., sepd., disintegrated, partly freed (if desired) of their oil content, and added to powd. coal in ratios varying from 1.5 to 4%. Cf. *C. A.* **33**, 3117[6].

Separating fuels such as coal and coke from heavier materials such as slate or cinders. Charles E. Pool (50% to Harry E. Davisson). U. S. 2,178,456, Oct. 31. App. is described, and a method of treating and segregating fuel such as coal and coke from materials having greater sp. gr. which comprises sepg. the materials in a bath the sp. gr. of which is intermediate of the sp. grs. of the fuel and the foreign material, removing the fuel from the upper level of the bath, adding powd. coal to the bath to form a top layer of coal on the surface of the bath, and coating the fuel with powd. coal as it is being removed from the bath by withdrawing it through the added layer of powd. coal floating on the bath.

Vertical retort setting for carbonizing coal, etc. Frederick J. West and Ernest West (to West's Gas Improvement Co. Ltd.). U. S. 2,178,026, Oct. 31. Various structural and operative details.

Vertical gas producer. V. I. Zhunko, L. S. Zaglodin and L. E. Lazebnik. Russ. 51,891, Oct. 31, 1937. Construction details.

Fuel-gas generator. Pécsi Kőszén- és Kokszkereskedelmi R. T. Hung. 121,797, Oct. 16, 1939. Structural details.

Generator for brown-coal gas. János Volenik. Hung. 121,314, Aug. 16, 1939. Structural details.

Pressure-operated valve for controlling the flow of gas through pipes to points of use. Marvin H. Grove. U. S. 2,177,825, Oct. 31. Various structural and operative details.

Gas odorizer suitable for treating gas bypassed from gas mains. Charles E. Gill (to Sharples Solvents Corp.). U. S. 2,178,519, Oct. 31. Various details of app. suitable for bringing a gas into contact with a treating liquid.

Recovering ammonium chloride from coke-oven gas liquor. Charles H. Heimbach and Norman B. Thompson (to National Tube Co.). U. S. 2,179,183, Nov. 7. An arrangement of app. is described, and a process for recovering NH_4Cl from coke-oven-gas liquor also contg. NH_4Cl and free NH_3, which involves passing the liquor through a multiple-effect evaporator so that the vapor driven from the liquor in the first effect is carried into the heater of the second effect and condensed, and so that foam forming in the first effect and contg. NH_4Cl is carried over into the heater of the second effect with the vapor and there condensed with the latter, the condensate from the heater being repassed through the evaporator to effect recovery of the NH_4Cl initially lost in the first effect by formation of the foam and the heater being vented to remove NH_3 gas sepg. therein from the liquor. The gas is subsequently redissolved in the liquor so as to be repassed through the evaporator whereby to permit a closed circulating system, portions of the liquor in the second effect are removed as required to keep the concn. of impurities in the system sufficiently low to prevent their interfering with the operation of the process.

W. F. FARAGHER AND STEWART S. KURTZ, JR.

Petroleum-ization—1940. Hugh W. Field. *Refiner Natural Gasoline Mfr.* **18**, 450–5; *Natl. Petroleum News* **31**, R-522–4; *Oil Gas J.* **38**, No. 27, 110, 112, 115, 271(1939).—A discussion of the newer, chem. methods of refining. C. H. Brooks

Refining characteristics of Illinois Basin crude oil. Gustav Egloff, G. B. Zimmerman and J. C. Morrell. *Oil Gas J.* **38**, No. 24, 81–6(1939); cf. *C. A.* **33**, 3123[2].—Extensive tabular data for several crude oils and reduced crude oils from the Illinois Basin. W. Andrew Wright

Ultraviolet absorption spectra of synthetic mineral oils. Edmond Vellinger and Bernard Thomas. *Compt. rend.* **209**, 882–4(1939).—Comparison of the ultraviolet (λλ 2000–4000) absorption spectra of crude Pennsylvania oil with the same partially (with H_2SO_4) and completely (with oleum) refined, whereby the aromatic hydrocarbons were partly and completely removed, with various synthetic oils shows the latter to resemble the unpurified samples, though in some cases there is evidence that naphthalene or more condensed cyclic hydrocarbons were present in addn. to aromatic hydrocarbons proper. C. A. S.

Burning various types of oil-refinery fuels. A. L Wilson. *Trans. Am. Soc. Mech. Engrs.* **61**, 699–704 (1939).—See *C. A.* **33**, 4774[6], 8965[1]. George Ayers

The regeneration step in the Solutizer process for the extraction of mercaptans. D. L. Yabroff, E. R. White and A. V. Caselli. *Refiner Natural Gasoline Mfr.* **18**, 509–15(1939).—Values of the stripping const., K_s, were obtained for the aliphatic RSH compds. through C_7, when the Solutizer soln. is regenerated. Diln. of the soln. increases the value from 3 to 7 times. The value appears to pass through a max. with increasing no. of C atoms. The max. is displaced toward larger nos. of C atoms by diln. Examples of the calcn. of the steam requirement for stripping are given. C. H. Brooks

Reaction rates in cracking. W. L. Nelson. *Oil Gas J.* **38**, No. 24, 132(1939).—Graphical data are given for reaction consts. from 700 to 1900°F. for hydrocarbons ranging from lubricating oil to methane. To simplify the study, the reaction rates were considered as unimol. W. A. W.

Catalytic cracking of aliphatic hydrocarbons. Gustav Egloff, J. C. Morrell, Charles L. Thomas and Herman S. Bloch. *J. Am. Chem. Soc.* **61**, 3571–80(1939).—A no. of hydrocarbons cracked at atm. pressure in the presence of an activated SiO_2-Al_2O_3 catalyst showed the following behavior: A mixt. of butenes underwent extensive catalytic isomerization to isobutene in the temp. range 385–600°, accompanied by polymerization and cracking; between 450 and 600° the isobutene content of the C_4 product was 24.1 ± 1.5%. Pentenes showed reactions similar to those of the butenes, yielding 50% of isopentenes at 400°. A mixt. of octenes underwent both catalytic isomerization to isooctenes and catalytic cracking to gaseous products consisting principally of equal amts. of butene and isobutene. The results are consistent with the theory that isomerization precedes cracking. In the temp. range 375–400° the conversion was over 80%. The primary catalytic reactions of cetene (I) in the range 300–450° was isomerization to isohexadecenes; the secondary reaction was cracking to lower-boiling olefins, accompanied by isomerization of normal olefinic products to isoolefins. The isohexadecenes catalytically cracked approx. 3 times as rapidly as I itself. Octane catalytically cracked 7–8 times as rapidly as in thermal decompn., and the catalytic products contained more C_5-C_7 hydrocarbons and less CH_4, C_2H_6 and C_2H_4 than the pyrolytic products. The temp. required for the catalytic cracking of octane was 200° higher than that required for octenes. I was catalytically cracked largely to C_3, C_4 and C_5 hydrocarbons. The products in the gasoline-boiling range contained both branched-chain and straight-chain hydrocarbons, in contrast to the products of I cracking, which were essentially all branched-chain. Although the behavior in thermal cracking of cetane and I is quite similar, cetane is far more stable toward catalytic cracking than I. In both cases, the products of catalytic cracking are quite different from those of pyrolytic cracking. Results are given in tables and curves. C. J. West

Partial volumetric behavior of the lighter paraffin hydrocarbons in the gas phase. B. H. Sage and W. N. Lacey. *Refiner Natural Gasoline Mfr.* **18**, 466–73; *Oil Gas J.* **38**, No. 27, 189–92, 195–7(1939).—The residual partial specific vols. of both components have been detd. for CH_4-C_2H_6, CH_4-C_3H_8 and CH_4-C_4H_{10} mixts. These quantities have been used, in equations developed by S. and L., to predict the volumetric behavior of several gas mixts. up to 3000 lb. per sq. in. with an accuracy of 5% or better. 23 references. C. H. Brooks

High-octane aviation fuel by the sulfuric acid alkylation process. Anglo-Iranian Oil Co. Ltd., Humble Oil and Refining Co., Shell Development Co., Standard Oil Development Co. and Texas Co. *Oil Gas J.* **38**, No. 27, 104–8(1939).—A cooperative program has produced a method of converting C_3-C_5 olefins into aviation gasoline of high octane rating. The process involves the formation of alkyl esters from olefins and coupling these with H_2SO_4 (90% or higher) as the catalyst. Mercaptans, amines and dienes also react with the acid and lower its activity. Temps. above 70°F. decrease yields; the optimum is 32–50°F. A typical process has a contact time of 20–40 min.; 96–100% acid; an acid-hydrocarbon ratio of 1:1 and 8–14% of olefin concn. with a 5:1 isobutane-olefin feed ratio. Flow sheets, product analyses and lead susceptibilities are given. W. Andrew Wright

Catalytic desulfurization to improve aviation blending naphthas. Walter A. Schulze and R. C. Alden. *Refiner Natural Gasoline Mfr.* **18**, 474–7, 515; *Oil Gas J.* **38**, No. 27, 199, 200, 202–4(1939).—Aviation naphthas are passed over a bauxite catalyst at 700 to 750°F. The treated material is practically sulfur-free. C. H. Brooks

Pyrolytic and polymerization processes for the preparation of antiknock gasoline from hydrocarbon gases. M. Marder. *Chem. App.* **26**, 340–3, 355–60(1939).—A review of currently used processes. 18 references. G. W. S.

Addition of nonmetallic organic substances to increase the antidetonating (knock) properties of motor fuels. A. D. Petrov. *Uspekhi Khim.* **8**, 365–77(1939).—**P. gives data on the octane and cetene nos. of a large no. of satd.,**

unsatd. and aromatic hydrocarbons, alcs., ethers and ketones in their mixts. with gasoline, and discusses the effects of chain branching and ozonization on the knock properties of motor fuels. F. H. Rathmann

Internal corrosion of gasoline pipe lines. L. C. Morris and W. A. Schulze. *Oil Gas J.* **38**, No. 27, 205, 210, 212, 213(1939).—An extensive investigation has shown dissolved or entrained air and aq.-treating solns. to be the main factor. Studies were made on the vol. ratios of the 3 components, also on velocity, temp., solids, etc. Mercaptobenzothiazole at concn. of 1 to 2 lb. per 1000 bbl. of gasoline was found to be effective in reducing barnacle growth and pitting of the pipe. W. Andrew Wright

Gas recycling. I. Injection of gas into oil reservoirs. H. L. Baldwin. *Oil Gas J.* **38**, No. 21, 46, 48, 53(1939).—A general discussion on gas injection and pressure maintenance. **II. Testing and sampling methods used on condensate wells.** Geo. Weber. *Ibid.* No. 22, 48–50, 52, 53.—A description of various methods of sampling and testing. 27 references. **III. Phase retrograde phenomena of hydrocarbon mixtures in condensate production.** A. L. Vitter, Jr. *Ibid.* No. 23, 48–50, 60.—Retrograde condensation is discussed with the aid of phase diagrams and vaporization consts. of mixts. and the application of such data to reservoir conditions is considered. The advantages and present limitations of such a study are discussed. 31 references. **IV. Compression requirements for recycling.** F. W. Laverty. *Ibid.* No. 25, 32, 33, 54.—The economics of recycling depends on compression costs. Calcn. methods are demonstrated. 44 references. **V. The case of unitization in recycling.** Geo. Weber. *Ibid.* No. 26, 38–40, 42.—The condition of the field and its structure are considered. The practice is discussed from the basis of conservation and equity. Federal control and type of contract required receives attention. 76 references. W. Andrew Wright

Properties of lubricating oil for engine. Itiro Aoki. *J. Fuel Soc. Japan* **18**, 915–26(1939).—A discussion. F. I. Nakamura

Principles and methods of refining lubricating oils and paraffin wax. T. Brown. *Oil Gas J.* **38**, No. 33, 103–8 (1939). A study to ascertain the shape of a quaternary equil. surface and the significance of the quarternary tie lines, so that calcn. would give necessary plant-design data Preliminary study was on the system: acetone, chloroform, water and acetic acid. Examn. at 25° of a double-solvent dewaxing process was also made. The oil was a narrow refinery cut and the waxes m. 17, 23.6, and 56.86°. An attempt was made to apply phase-rule principles to wax sweating. The solvent refining of paraffin wax was studied. Relations between mol. wt. and m. p. of *n*-paraffins were found. Curves for odd and even nos. of C atoms converge above C_{22}. W. Andrew Wright

Power factor of insulating oil. H. W. Bousman. *Gen. Elec. Rev.* **42**, 409(1939).- The oil must be fluid at low temp., resistant to the effect of high elec. stress and resistant to chem. change. A simple cell for testing oils is described. C. G. F.

Viscosity index of lubricating oils. E. W. Dean, A. D. Bauer and J. H. Berglund. *Ind. Eng. Chem.* **32**, 102–7 (1940).—Previous viscosity index (V. I.) scales for petroleum oils have been based on Saybolt Universal viscosities and the consts. used in making the calcns. did not extend below 40 sec. Saybolt Universal viscosity at 210°F. The present paper reports the prepn. and availability of a table of kinematic consts. covering the range of 2.0–75.0 centistokes (equiv. to 32.8–349 Saybolt sec.) at 210°F. The low viscosity extension adopted here and covering the range below 4.20 centistokes (40 sec. Saybolt) at 210°F. is defined in the terms of the following equations: For 100 V. I.: $Y = 1.4825X + 0.91375X^2$; for 0 V. I.: $Y = 1.655X + 1.2625X^2$, where Y = kinematic viscosity at 100°F. and X = kinematic viscosity at 210°F. Saybolt Universal viscosities are not desirable for this low range, and the extension is in centistokes only. Although these equations extend to zero viscosity, they cannot be used in the range where the oils they represent have vapor pressures that are too high to permit accurate viscosity detns. at 210°F. The lower limit of the table that has been prepd. is 2.0 centistokes at 210°F. (32.8 sec. Saybolt). With this extension the V. I. scale now covers all ordinary lubricating oils. V. I. can be estd. conveniently by the use of nomographic charts of the type included in this article. Saverio Zuffanti

Practical methods of testing lubricants. J. H. Evans. *J. Inst. Petroleum* **25**, 729–50(1939).—A discussion of the testing of the following types of lubricants: lime-soap greases, soda-soap greases, mixed-base greases, Al stearate, mineral oils of varying degrees of refinement from light to heavy cylinder stock, Pb soap and extreme-pressure type oils and greases. A picture and specifications of the Karns Maag Consistometer are included. Specifications for the above lubricants are given. The use of fillers such as talc, graphite, waxes, rosin, clay or mica is not recommended in any greases intended for use with antifriction bearings, as they not only lap the components in, but continue wearing them away, causing frequent replacements. Tests on the consistency of the above greases at increasing temps. are included. The soda-soap greases examd. were grades universally recommended for the lubrication of antifriction bearings, and the expts. show them to thin down more quickly on heating than the lime-soap greases. Incidently these 2 types of greases account for about 95% of the grease-lubricated applications. The general softening range appears to lie between 140° and 160°F. and even though the m. ps. are so much higher than the lime-soap greases, they thin down between these temps. to such an extent that only very efficient enclosures could retain them. The lime-soap greases soften gradually, and are more viscous at the higher temps. The m. ps. of the greases above are given. Saverio Zuffanti

Behavior of various engine and gear lubricants in seizure tests. D. Clayton. *J. Inst. Petroleum* **25**, 709–28(1939). —An investigation of the effect of various lubricants on the seizure characteristics of hard steel in the 4-ball app. Ordinary lubricants, as well as extreme-pressure lubricants, give significant results. Two kinds of extreme-pressure lubricants were tested, early ones of the sulfurized-fatty oil type and more recent ones of the Pb soap-sulfur type. The former behave in a similar manner to the mineral and fatty oils, but with superior qualities. The latter are different, giving appreciable wear at the low loads, and slight rises of friction at moderate loads instead of a sudden rise to a high value at high loads; moreover, they take an enormously high load without welding occurring. Tests have been made of the effect on a mineral oil of the proportion of an extreme-pressure dope of the sulfurized-fatty oil kind, and it has been found that a range of qualities could be obtained. Kerosene and gasoline, although causing appreciable wear even at low loads, behave moderately throughout, the damage when "scuffing" occurs being less than with most mineral oils. There is some discussion of the applicability of the results to gear lubrication. Saverio Zuffanti

Tentative laboratory test for the ring-sticking properties of lubricants. J. C. McNicol, C. G. Williams and P. V. Lamarque. *J. Inst. Petroleum* **25**, 751–9(1939).—A simple lab. test for detg. the oxidation and ring-gumming properties of engine lubricants is described. The test, which consists principally in measuring the strength of a thin oxidized film of the lubricant, has been used for a preliminary study of the oxidation process over a range of temps. and exposure times with 1 lubricant, and at a fixed temp. with a no. of gasoline- and Diesel-engine lubricants of known service performance. Although the data obtained so far are not extensive, it is shown that, in lubricants which are prone to cause ring-sticking in Diesel engines, the strength of the oxidized film is much higher than with lubricants giving comparative freedom from ring-sticking. In addn., it is shown that high film strength is assocd. with high viscosity index of the lubricant. In a limited no. of gasoline-engine lubricants examd., volatility appeared to be a better criterion than the strength of the oxidized film. Saverio Zuffanti

Flow characteristics of lime-base greases. J. F. T. Blott and D. L. Samuel. *Ind. Eng. Chem.* **32**, 68–72

(1940).—By use of a capillary viscometer over a certain range of shearing stresses, the abs. viscosities at 25° of a no. of lime-base greases were detd. Some approx. yield values were measured in a concentric-cylinder torsion viscometer. Some empirical measurements were made on the flow of the greases under comparatively high shearing stresses. Math. expressions to the flow curves in the capillary viscometer were found which agree with the exptl. results except in the region of the yield values. These expts. suggest that the viscosity of the oil base is the main factor detg. the viscosity of the grease at shearing stresses well removed from the yield value and that the soap content probably controls the magnitude of the yield value.
Saverio Zuffanti

Routine method of analysis of bearing greases. G. W. Bond. *J. S. African Chem. Inst.* 22, 57-62(1939).—The method devised by B. (cf. *J. Assoc. of Certificated Engrs.* (S. A.) 9, 104(1935)) is compared with that of the S. A. Standards Institution (No. 10, (1935)). The definite advantages claimed for this method are greater rapidity and accuracy in the detns. The chief procedure employed is acetone extn. of the free fatty acids and free oils. The actual soap present is detd. by weighing. A. B. G.

Some physical constants of bitumen. P. C. Blokker, *et al. Angew. Chem.* 52, 643-8(1939).—A comprehensive treatise covering the following phys. properties: sp. gr., vol. coeff. of expansion, sp. heat, thermal cond., breakdown voltage, dielec. losses and consts., sp. elec. resistance, surface tension and total surface energy, and permeability to water vapor. Many data (including literature values) as well as analytical procedures and app. are given. 17 references. Karl Kaffmermeyer

Ni alloys in production, transportation, refining and combustion of oil (Rabbitt) 9. Aliphatic polyamines [for use as lubricants] (U. S. pat. 2,178,522) 13.

Trendelenburg, Reinhard: Das Holz als Rohstoff. Seine Entstehung, stoffliche Beschaffenheit und chemische Verwertung. Munich and Berlin: J. F. Lehmanns Verlag. 435 pp. M. 14.50. Reviewed in *Nature* 144, 924 (1939).

Resolving oil-water emulsions such as those of petroleum oil. Raymond B. Millard. U. S. 2,179,131, Nov. 7. App. is described and a method which involves heating emulsions to a resolving temp. while flowing in a confined stream through a heating zone immersed in a body of aq. liquid maintained in a sepg. zone, introducing the heated emulsion directly into the body of aq. liquid in the sepg. zone to heat the body of aq. liquid to a suitable sepg. temp., therein sepg. the emulsion into an aq. phase which merges in the body of aq. liquid and an oil phase which accumulates above the upper surface of the body of aq. liquid, and thermo-siphonically circulating a confined stream of aq. liquid from the body thereof through the heating zone to a point within the oil phase and then discharging the aq. liquid downwardly through the oil phase and in direct contact therewith into the body of aq. liquid to maintain the body of aq. liquid and the oil phase at the sepg. temp.

Refining oils such as petroleum distillates. Sumner E. Campbell. U. S. 2,179,008, Nov. 7. An arrangement of app. is described, and a process of treating oil with reagents which involves introducing independent streams of oil and reagent into the lower part of a reaction zone contg. contact material such as quartz or glass substantially submerged in the reagent, passing the streams upwardly through the reaction zone to cause independent contact of the oil and reagent, and then sepg. the oil and reagent.

Recovering pyridine in the solvent refining of oils. James W. Weir (to Edeleanu Ges. m. b. H.). U. S. 2,178,506, Oct. 31. An arrangement of app. is described, and a process of refining a wax-contg. mineral oil which comprises dewaxing by means of anhyd. tech. pyridine as the diluent and admixing the dewaxed oil-pyridine soln. thereby obtained with an aq. alk. soln. for the purpose of producing a raffinate phase and an ext. phase whereby both phases absorb water from the aq. alk. soln., and which involves distg. the water-contg. raffinate and ext. solns. separately, thereby obtaining a greater yield of anhyd. pyridine to be returned to the dewaxing process than is obtainable in the absence of ramnate oil or ext. oil in the distn. step.

Conversion of hydrocarbon oil. Joseph G. Alther (to Universal Oil Products Co.). U. S. 2,179,079, Nov. 7. An arrangement of app. is described, and a process of cracking and continuous coking which comprises quickly heating a residual oil to a temp. of about 480–525° by passing the same through a heating coil subjected to high rates of heating by direct radiation from flames and hot refractory surfaces in a furnace without allowing the oil sufficient time in the heating coil to cause substantial coke formation and deposition therein, simultaneously and separately heating a lower-boiling oil to a cracking temp. of about 510–565°, discharging resultant highly heated products of both heating steps onto the moving surface of a conveyer disposed within a coking zone and thereon effecting reduction of the high-boiling components of the heated products to coke without addnl. heating, removing the coke from the coking zone, separately removing vaporous hydrocarbons supplied to and evolved within the coking zone therefrom, fractionating the vapors to form a relatively clean condensate of lower-boiling characteristics than the first-mentioned oil, supplying the condensate as the lower-boiling oil to the second-mentioned heating step, subjecting resultant fractionated vapors of the desired end-b. p. to condensation and recovering and sepg. the resulting distillate and uncondensed gases.

Cracking hydrocarbon oils. Lyman C. Huff (to Universal Oil Products Co.). U. S. 2,177,829, Oct. 31. In the selective cracking of relatively low-boiling and high-boiling hydrocarbon oils by sep. treatment of streams of oil of different b.-p. ranges, mixing the cracking products and continuing the cracking of the mixt. and fractionating this product, the fractionated vapors of the desired end b. p. are further fractionated into gasoline vapors of the desired end b. p. and satisfactory antiknock value and a higher-boiling condensate including high-boiling gasoline fractions of unsatisfactory antiknock value. The desired gasoline vapors are condensed and recovered. The higher-boiling condensate is subjected to reforming conditions of cracking temp. and substantial superatm. pressure in another independently controlled cracking zone; regulated quantities of the highly heated products from the last-mentioned cracking zone are introduced into a coking zone. Vaporous products from the coking zone are supplied to another low-pressure sepg. zone, liquid components from the first fractionating zone for mixed conversion products are introduced into the low-pressure sepg. zone to which the vaporous products from the coking zone are supplied. Residual liquid from this low-pressure sepg. zone are quickly heated in another separately controlled cracking zone to a temp. sufficient to induce subsequent coking of the residual liquid. The heated products from the last-mentioned cracking zone are introduced into the coking zone, wherein their high-boiling components are converted to substantially dry coke. Vaporous products from the low-pressure sepg. zone are fractionated to form a reflux condensate, which is supplied to the first-mentioned fractionating zone. Fractionated vapors of the desired end b. p. and comprising materials within the boiling range of gasoline from the last-mentioned fractionating zone are condensed and recovered.

Cracking hydrocarbon oils. Le Roy G. Story (to The Texas Co.). U. S. 2,178,329, Oct. 31. An arrangement of app. is described, and a process for the manuf. of gasoline, which comprises subjecting higher-boiling oil in mixt. with a minor proportion of normally gaseous hydrocarbons and in the absence of gaseous products of combustion to cracking conditions of temp. and pressure whereby a substantial amt. of lower-boiling products contg. oil of the gasoline-boiling range is formed from the higher-boiling oil and gaseous hydrocarbons, sepg. the reaction products into a fraction heavier than gasoline, a gasoline fraction and nor-

mally gaseous hydrocarbons, fractionating the normally gaseous hydrocarbons to sep. a fraction predominating in C_3 and C_4 hydrocarbons, recycling the fraction of C_3 and bringing C_4 hydrocarbons to the cracking operation and the oil and gaseous hydrocarbons into contact while under cracking conditions with about 1/2 to 1% of O as a catalyst to accelerate the conversion of the oil and gases to gasoline hydrocarbons.

Cracking hydrocarbon oils. James W. Gray and Jesse S. Walton (to Gasoline Products Co.). U. S. 2,178,834, Nov. 7. An arrangement of app. is described, and a process for treating high-boiling hydrocarbons to produce low-boiling hydrocarbons, which comprises bringing vapors in a primary fractionating zone into contact with a relatively heavy oil and collecting unvaporized heavy oil therein, thereafter subjecting vapors from the primary fractionating zone to further fractionation in a secondary fractionating zone to sep. relatively high-boiling oil therefrom as reflux condensate, passing reflux condensate thus obtained as a stream through the first portion of a cracking zone maintained under high-temp. and high-pressure conditions to produce conversion of such reflux condensate into lower-boiling products, injecting unvaporized heavy oil from the primary fractionating zone into a portion of the stream of high-temp. cracked products leaving the first portion of the cracking zone, passing such combined stream through the latter portion of the cracking zone maintained at cracking temp., injecting another portion of the stream of high-temp. cracked products into the latter portion of the cracking zone at a point subsequent to the injection of such heavy oil to raise the temp. thereof and effect further cracking of the heavy oil, passing the resulting stream of cracked products leaving the latter portion of the cracking zone to a sepg. zone wherein vapors and cracked residue are sepd., and passing such vapors into the primary fractionating zone.

Cracking and coking heavy hydrocarbon oils such as residual oils. Joseph G. Alther (to Universal Oil Products Co.). U. S. 2,179,080, Nov. 7. App. is described, and a process for the cracking and coking of heavy hydrocarbon oils, which comprises quickly heating the oil to a high conversion temp. while passing the same in a continuous stream through a heating coil subjected to high rates of heating by heat radiated directly to its surface from materials undergoing combustion and the hot refractory confining walls, introducing the heated products into a sepg. zone wherein the resultant heavy pitch-like residue separates from their vaporous components. The vaporous components are removed from the sepg. zone, subjected to condensation and the resulting condensate and uncondensed gases are sepd. The pitch-like residue is discharged from the sepg. zone onto the moving surface of a continuous conveyor within a coking zone causing the pitch-like residue to spread out in a relatively thin layer over the upper surface of the conveyor and it is reduced thereon to a relatively thin mass of coke-like material by means of its contained heat and by means of heat radiated thereto from the relatively hot refractory walls which sep. the coking zone from the combustion chamber. The coke-like material is passed on the conveyor beneath the combustion chamber at which point coking and devolatilization of the coke to the desired degree are completed by heating the material on the conveyor to a high temp. by heat radiated directly to its upper surface from materials undergoing combustion in the combustion chamber and the hot refractory walls thereof, the resulting combustion gases are removed from the combustion chamber without permitting any appreciable quantity thereof to commingle with the hydrocarbon vapors and gases evolved within and separately removed from the coking zone outside the combustion chamber, and the deposited bed of coke is continuously removed from the conveyor and quenched and discharged from the system.

Distilling and cracking hydrocarbon oils. Wayne E. Kuhn (to Texas Co.). U. S. 2,178,838, Nov. 7. An arrangement of app. is described, and a method of treating hydrocarbon oils to form therefrom low-boiling hydrocarbons suitable for motor fuel which comprises distg. crude oil to sep. therefrom a reduced crude, a virgin gas-oil condensate and a naphtha condensate, separately subjecting reduced crude oil thus obtained to relatively mild cracking conditions to effect conversion thereof to lighter products including a substantial proportion of constituents above the gasoline-boiling range, sepg. the resultant cracked products into vapors and residue in a sepg. zone, separately subjecting virgin gas oil thus obtained to relatively more drastic cracking conditions to effect conversion into lighter products including gasoline constituents, separately subjecting naphtha thus obtained to cracking conditions of temp. and pressure adequate to effect reforming of the naphtha to improve the antiknock value thereof, introducing the resultant hot reformed products into the sepg. zone to aid in the vaporization of the cracked reduced crude products, passing the sepd. vapors from the sepg. zone to a fractionating zone, where the vapors are fractionated to form a heavy condensate and a lighter condensate, separately subjecting lighter condensate thus obtained to cracking conditions of temp. and pressure by passage as a stream through a heating zone of restricted cross-section to effect conversion into lighter products including gasoline constituents, introducing heavy condensate from the fractionating zone into an intermediate point of the last-mentioned heating zone to effect cracking of the heavy condensate, passing the resultant cracked products into a second sepg. zone wherein vapors sep. from residue, passing the sepd. vapors to a second fractionating zone wherein the vapors are fractionated to form reflux condensate and lighter distillate and directing reflux condensate from the second fractionating zone to the heating zone of restricted cross-section to effect cracking of the reflux condensate.

Gasolinic hydrocarbons. Vladimir N. Ipatieff and Herman Pines (to Universal Oil Products Co.). U. S. 2,170,306, Aug. 22. Isobutane is alkylated with butylenes in the presence of isobutylene and of $AlCl_3$ at temps. of 0° or below. Cf. *C. A.* 34, 255[4].

Gasoline from gaseous hydrocarbons. Harold V. Atwell (to Process Management Co.). U. S. 2,178,824, Nov. 7. An arrangement of app. is described, and a method of producing motor fuel of high antiknock value, which involves causing CO and H to react over a catalyst such as Co and thoria on kieselguhr at a temp. and pressure such that liquid hydrocarbons in the gasoline-boiling range are formed, sepg. normally gaseous hydrocarbon constituents of the reaction products contg. more than one C atom and heating them to effect substantial cracking, mixing with the resultant cracked product normally liquid constituents from the first-mentioned reaction mixt., and heating the resulting mixt. to effect conjoint conversion of normally liquid and polymerization of normally gaseous hydrocarbons in it.

Motor fuels. Irving E. Muskat (to Pittsburgh Plate Glass Co.). U. S. 2,178,403, Oct. 31. A gasoline which may comprise principally volatile hydrocarbons such as those of straight-run gasoline or cracked gasoline or their mixts. is given improved antiknock properties by incorporation of about 5% or more of unsatd. aliphatic alcs. and ethers such as allyl or diallyl alc. or diallyl ether.

Motor fuel. Euphime V. Bereslavsky. Can. 384,497, Oct. 10, 1939. The S content of a high-boiling petroleum hydrocarbon is decreased to less than 0.25% by wt. of the fuel and an ignition accelerator, e. g., neopentyl nitrate, is added, to produce a compression-ignition fuel.

Polymerization of olefins. Howard L. Gerhart and Carl M. Hull (to Standard Oil Co.). Can. 384,808, Oct. 24, 1939. Normally gaseous olefins are continuously polymerized to normally liquid products by contact of the liquefied olefins with gaseous BF_3 at about 50–200°F. The reaction products are passed to a second zone of higher temp. to liberate BF_3 gas, which is returned to the process. An app. is described.

Polymerization of olefins. Howard L. Gerhart and Maurice H. Arveson (to Standard Oil Co.). Can. 384,809, Oct. 24, 1939. Gaseous hydrocarbons contg. compds. such as butylene and propylene are brought at about 300–500°F. and a pressure of about 100–500 lb./sq. in., into

contact with a small amt. of BF_3. Heavy polymerization products are removed from the lower part of the contact chamber, BF_3 and gaseous products are passed into a low-temp. zone for further reaction to form BF_3-hydrocarbon complexes, which are returned to the high-temp. zone to recover BF_3 and the liquid products of the reaction are scrubbed to remove traces of BF_3 and fractionated to sep. components of the gasoline-boiling range from higher-boiling and lower-boiling components. An app. is described.

Polymerizing gaseous olefins. Arthur H. Boultbee (to Shell Development Co.). U. S. 2,171,207, Aug. 29. An arrangement of app. is described, and a process of polymerizing normally gaseous hydrocarbons of the type produced in cracking, comprising tertiary base and nontertiary base olefins to produce gasoline-type motor fuel. The hydrocarbon is sepd. into a light fraction consisting essentially of ethane and lighter gases, a middle fraction consisting essentially of propane and propylene, and a heavy fraction substantially free from propane and lighter hydrocarbons comprising tert. base and nontert. base olefins. The heavy fraction is brought into contact with a polymerization catalyst at an elevated temp. under conditions to polymerize predominantly the tert. base olefins while only partially polymerizing the less reactive nontertiary base olefins. The polymer is sepd. from the unchanged olefin-contg. fraction, the latter combined with the middle fraction, the mixt. subjected to a thermal noncatalytic polymerization to produce addnl. polymers, the polymers are sepd. from residual gaseous hydrocarbons, and the latter returned to the fractionating zone.

Reduction of the permeability of a porous formation in an oil or a gas well. John J. Grebe and Sylvania M. Stoesser (to Dow Chemical Co.). Can. 385,751, Dec. 19, 1939. A soln. or dispersion comprising a water-insol. viscid material and a water-sol. org. solvent, e. g., an acetone-sol. tar and acetone, is introduced into the well and then into the formation in the presence of water.

Laminated material suitable for oil containers. Robert E. Burk and Everett C. Hughes (to Standard Oil Co. of Ohio). U. S. 2,178,447, Oct. 31. Containers such as those for oil or grease are formed with a layer of cellulose material such as chip board or chestnut board and an oil-resistant exposed inner layer of water glass, the cellulose material being moisture-satd. and provided exteriorly with a layer such as an asphalt compn., to prevent loss of moisture.

Compounds of the perylene series for coloring hydrocarbon oils, waxes, fats, plastics, lacquers, etc. Heinrich Neresheimer and Anton Vilsmeier (to General Aniline Works). U. S. 2,178,521, Oct. 31. By heating, at 180–300°, a reaction product of a halide of an acid, such as benzoyl chloride, and a benzanthrone with a compd. contg. at least 6 C atoms, which may be an aliphatic or cycloaliphatic unsatd. hydrocarbon or alc., ester, mercaptan, ether or thioether, in the presence of an acid-condensing agent such as HCl and $ZnCl_2$, products are obtained which, generally, color paraffin oil yellow with an olive fluorescence. Various examples with details are given. Cf. *C. A.* **33**, 6480[3].

Oil filter suitable for use with internal-combustion engines. Harry D. Crawford. U. S. 2,178,930, Nov. 7. Various structural details.

Refining hydrocarbon oil. Leon W. Cook (to Texaco Development Corp.). Can. 385,496, Dec. 5, 1939. Residual lubricating oil contg. hard and soft asphalt, dark-colored constituents, and oil of low and high viscosity index is dild. with sufficient propane to ppt. hard asphaltic constituents, the partially deasphalted mixt. is extd. with a mixt. of furfural and mixed chlorophenols contg. about 60–70% of the para isomer, the amt. of chlorophenol being enough to dissolve the remaining asphaltic constituents without substantially increasing the solvent action of furfural upon constituents of high viscosity index, an ext. phase is formed comprising asphaltic and dark-colored constituents and substances of low viscosity index dissolved in the bulk of the solvent, and a raffinate phase comprising oil of high viscosity index mixed with some of the solvent.

Refining hydrocarbon oils such as California lubricating oils. Ernst Terres, Josef Moos and Erich Saegebarth (to Edeleanu G. m. b. H.). U. S. 2,178,515, Oct. 31. A mixt. contg. a preponderant proportion of acetanilide is used as a selective solvent for aromatic constituents, etc., in effecting their sepn. from paraffinic constituents, for increasing the viscosity index of the oil treated.

Device for removing paraffin from oil wells. Cuthbert A. Still and Lawrence M. Still (L. M. Still to Aldrich C. Still). U. S. 2,179,475, Nov. 7. Various structural details.

Dewaxing petroleum oils. Le Roy G. Story (to The Texas Co.). U. S. 2,178,328, Oct. 31. Dewaxing of an oil such as a petroleum lubricating stock is effected by heating the oil to about 82° in the presence of a soap such as Al stearate 0.1–0.3% which is substantially insol. in water and effectively modifies wax crystn., chilling the mixt. to ppt. wax, and sepg. the wax by filtration.

Dewaxing hydrocarbon oil. Leon W. Cook and Charles C. Towne (to Texaco Development Corp.). Can. 385,648, Dec. 12, 1939. Filtration of wax is improved by adding a small proportion of the reaction product of rubber with a Sn or B halide or halogen acid to a lubricating oil in the presence of a chem. agent capable of depolymerizing the rubber; e. g., the reaction product of rubber and $SnCl_4$ is added together with glacial AcOH, the oil chilled to ppt. wax and the mixt. filtered. Cf. *C. A.* **33**, 4014[1].

Dewaxing lubricating oils. Edward J. Martin (to Sinclair Refining Co.). U. S. 2,178,078, Oct. 31. Dewaxing of a lubricating oil stock is effected by use of a solvent mixt. which may include C_6H_6 or toluene, ethylene glycol monomethyl ether and $PhNO_2$ (suitably after a preliminary extn. of the stock with $PhNO_2$).

Lubricating oils. Paul L. Salzberg (to E. I. du Pont de Nemours & Co.). U. S. 2,178,610, Nov. 7. A small proportion of an ester of an acid of P contg. at least one naphthenyl radical, such as trinaphthenyl trithiophosphite, is added to a lubricating oil such as a paraffin oil to reduce corrosion under high pressures, etc.

Lubricating oils of high film strength. Bert H. Lincoln and Waldo L. Steiner (to Lubri-Zol Development Corp.). U. S. 2,178,534, Oct. 31. A lubricating oil is mixed with 0.02–10% of a chlorinated aliphatic compd. such as methyl chlorostearate and with 0.02–10% of an org. S compd. such as butyl sulfide, both of which added compds. are sol. in the oil and have a b. p. above 140°. Numerous examples are given.

Refining lubricating oils with selective solvents. Louis A. Clarke (to The Texas Co.). U. S. 2,178,321, Oct. 31. An arrangement of app. is described, and a method of solvent refining high-grade paraffin-base lubricating oil and low-grade naphthene-base lubricating oil derived from different crude sources which comprises extg. the paraffin-base lubricating oil stock with a selective solvent comprising a chlorophenol mixt. contg. about 15% phenol, 31% orthochlorophenol, 51% parachlorophenol, and 3% dichlorophenol, forming a primary raffinate phase comprising highly paraffinic oil and a primary ext. phase rich in solvent and relatively paraffinic constituents of the oil, sepg. the two phases, causing the primary ext. phase to flow through a sep. extn. zone countercurrently to the naphthene-base lubricating oil and in the presence of fresh solvent, forming a secondary ext. phase contg. low viscosity index oil, and a secondary raffinate phase comprising oil of relatively higher viscosity index, and sepg. the two phases.

Voltolized antioxidant blending agent for use in refined petroleum lubricating oils. Peter J. Wiezevich (name now changed to Peter J. Gaylor; to Standard Oil Development Co.). U. S. 2,178,769, Nov. 7. A process of prepg. an antioxidizing hydrocarbon compn. for use in lubricating oil involves treating crude petroleum oil with a selective solvent such as liquid SO_2 or phenol to remove the nonparaffinic components and subjecting the latter to silent elec. discharge polymerization.

Sulfurized sperm oils and the like suitable for use with mineral lubricating oils. Herschel G. Smith and Troy L.

Cantrell (to Gulf Oil Corp.). U. S. 2,179,063, Nov. 7. Fat acid monoester material such as sperm oil is sulfurized at temps. of about 180–230° to produce sulfurized esters contg. minor amts. of by-products deleterious in lubricating compns. and such by-products are subsequently removed by agitation with an acid-washed clay. U. S. 2,179,064 relates to a similar use of acid-washed clay for refining a mixt. of a mineral oil with sulfurized sperm oil or the like.

Sulfurized esters of fatty acids. Herschel G. Smith (to Gulf Oil Corp.). U. S. 2,179,065, Nov. 7. An unsatd. fatty aliphatic monoester having the general formula RC=O(O)R′ in which R and R′ represent straight-chain aliphatic groups, one of which is satd. and the other unsatd., is sulfurized, as by heating with S, to saturate the unsatd. group and produce a substantially neutral S compd., such as sulfurized decylene palmitate which is suitable for *use with lubricating oils*, etc. U. S. 2,179,066 relates to the sulfurization of sperm oil, etc.

Lubricant. Seymour W. Ferris (to Atlantic Refining Co.). Can. 384,094, Sept. 19, 1939. Operative details are described for production of a viscous mineral oil suitable for lubricating internal-combustion engines, the oil having a viscosity-gravity const. of 0.827–0.791, a Saybolt Universal viscosity at 210°F. of 60–160 sec., and being substantially free of mineral oil constituents having a viscosity-gravity const. 0.07 higher than the viscosity-gravity const. of the oil itself.

Mineral-oil lubricants. John M. Musselman (to Standard Oil Co. of Ohio). U. S. 2,178,455, Oct. 31. To render it stable at high temps., a mineral oil of lubricating viscosity is mixed with a small proportion (suitably about 1% or less) of *o*-nitroso-*m*-cresol, nitrosobenzene or other compd. of the general formula $C_6R.NO$ in which R represents H, or H_3CH_3OH or $H_2(CH_2)_2OH$.

Lubricants containing sulfohalogenated monoesters. Herschel G. Smith and Troy L. Cantrell (to Gulf Oil Corp.). U. S. 2,179,062, Nov. 7. A lubricant suitable for lubricating Cd-Ag and other special alloy bearings under relatively high bearing temps., pressure and speeds, without corroding the bearings, comprises a mineral oil mixed with 0.2–2.5% of a substantially neutral, sulfochlorinated monoester contg. S 2–6% and Cl 2–7% and which is an addition product of S chloride and sperm oil or other unsatd. aliphatic monoester of the general formula $Me(CH_2)_nCH{:}CH(CH_2)_nC(.O)OCH_2(CH_2)_nCH{:}CH(CH_2)_n$-Me wherein *n* is 1 to 9, the amount of the sulfochlorinated monoester dissolved in the oil being sufficient effectively and substantially to retard the destructive action on said alloy bearings which would normally occur in the absence of said sulfochlorinated monoester.

Lubricants suitable for transmission and differential gears, etc. Carl F. Prutton and Albert K. Smith (to Lubri-Zol Development Corp.). U. S. 2,178,513, Oct. 31. As a principal lubricant, use is made of a halogenated org. ring compd. such as a chlorinated diphenyl ether and S in soln. in active form (suitably in lard oil or fish oil). U. S. 2,178,514 relates to lubricating compns. suitable for use under extreme pressures, e. g., in die-drawing metals; they comprise a lubricating oil mixed with an addn. agent, such as S, Cl or H_2S, capable of reacting with the metallic surface being lubricated and with an org. phosphite or phosphate (such as triphenyl phosphite or phosphate) having a vapor pressure less than atm. at 140°, which serves to inhibit corrosion.

Stable and noncorrosive mineral-oil lubricants. Herschel G. Smith (to Gulf Oil Corp.). U. S. 2,179,060, Nov. 7. A mineral-oil lubricating base is mixed with sulfurized sperm oil. U. S. 2,179,061 relates to a uniform blend of a mineral-oil lubricating base with a minor proportion (suitably about 10–14%) of a sulfurized fatty monoester derived from an ester having the general formula RC=O(O)-R_1 in which R and R_1 represent aliphatic groups at least one of which is unsatd. prior to sulfurization, such as a sulfurized oleate of oleyl alc. or ethyl oleate.

Lowering the pour point and inhibiting the oxidation of hydrocarbon oils for use as lubricants, etc. Henry G. Berger, William H. James and Darwin E. Badertscher (to Socony-Vacuum Oil Co.). U. S. 2,177,923, Oct. 31. A mineral oil such as a motor or transformer oil is mixed with (suitably about 0.1–0.5%) a product obtained by reaction of di- or tetra-wax phenol with *o*-phosphitobenzoyl chloride at an elevated temp. until the evaluation of HCl has substantially ceased or with various products obtained by reaction of a phenol, 1-naphthol or 9-anthrol in which at least one H is substituted by a high-mol.-wt. aliphatic hydrocarbon radical, the remaining H being substituted or not by the groups consisting of hydroxyl, aryl, alkyl, aralkyl, aroxy and alkoxy radicals, with a compd. having the general formula: $O{:}POC{:}CR'.CR'{:}CR'.CR'{:}CCO$-Cl in which the R's are from the group consisting of H, alkyl, aryl and alkaryl radicals, the final product of reaction possessing the property of depressing the pour point and inhibiting oxidation of the oil. Various examples with details are given.

Sulfurized cutting oil. Wm. H. Kobbe (to The Texas Co.). U. S. 2,178,325, Oct. 31. A light lubricating oil is used with an admixt. of about 2–6% of the product obtained by treating a polymer of dihydronaphthalene of the formula $C_{40}H_{40}$ to temps. sufficiently high to form a homogeneous product at a temp. of at least about 140° and not greatly above 165°. Cf. *C. A.* **33**, 8986[2].

Engine oil mixture. Herschel G. Smith (to Gulf Oil Corp.). U. S. 2,179,067, Nov. 7. A lubricant suitable for use in the crankcases of internal-combustion engines operating at high pressures and high temps. comprises a petroleum lubricating oil mixed with refined sulfurized sperm oil and tritolyl phosphate, butylstearate, etc.

Asphalt from petroleum residuum. Robert E. Burk and Charles H. Whitacre (to Standard Oil Co. of Ohio). U. S. 2,179,208, Nov. 7. A petroleum residuum is air-blown for 1–30 hrs. or longer in the absence of an added catalyst at a temp. of about 150–260°, and then heated to at least about 150° with a small amt. of a polymerizing catalyst such as H_2SO_4, $FeCl_3$ or B fluoride. Cf. *C. A.* **33**, 4419[1].

Asphalt from oil shale. A. K. Mityurev. Russ. 51,958, Oct. 31, 1937. Asphalt is produced by heating shale with inorg. substances, e. g., sand, preliminarily brought to a temp. of 700–1000°.

Purifying wood creosote. Tsentral'nyi Nauchno-Issledovatel'skii Lesokhimicheskii Institut "Tsnilkhi" (inventors, V. P. Sumarokov and V. D. Ugryumov). Russ. 51,841, Sept. 30, 1937. Creosote is first treated with NaOH soln. in the amt. of 5–15% of that required for complete soln. of the creosote. The alk. soln. is sepd. and the creosote then treated with excess NaOH. The alk. solns. are separately treated with H_2SO_4 and extd. with Et_2O. The exts. are distilled. The product from the first alk. treatment is less dense and lower in MeO than the product of the second alkali treatment.

Separation of pyroligneous liquor. Jesse M. Coahran. Can. 385,531, Dec. 12, 1939. In scpg. constituents of pyroligneous liquor, by a preliminary distn. to remove tar followed by a fractional distn. to remove methanol and a subsequent cold extn. with a volatile solvent to remove acetic acid, the hot distillate is passed from the preliminary distn. into heat-exchange relation to the cooler acid soln. to drive off the solvent and cool and partially condense the distillate before fractional distn., while only a portion is in the vapor phase; thus the latent heat of vaporization of the portion is utilized in the fractional distn. An app. is described.

23—CELLULOSE AND PAPER

CARLETON E. CURRAN

Diameter variation in cellulose fibrils. A. J. Bailey and R. M. Brown. *Ind. Eng. Chem.* **32**, 57–63(1940).—Various plant fibers, including cotton, wood pulps and wood shavings, were disintegrated by mech. means alone and by beating after chem. treatments. Measurements of fibril diams. were made and analyzed statistically, and the results showed that cellulose fibrils exist as uniform and true morphological units with a more or less common and const. diam., 0.9-1.0 μ. This diam. is independent of origin, chem. treatment or mech. processing of the fibril. At least 2 phys. materials occur in the fiber wall: one a compact, dense, unit fibril incapable of being gelatinized in water by ordinary methods, and the other a substance forming a hydrogel in water. Fiber laminations have alternately strong and weak spots; the distance from center to center of either is about 1 μ. Anastomosing of fibrils appears to be extremely improbable, and zone markings on drastically swollen fibers are a doubtful basis from which to infer fibril dimensions. Freeness, viscosity and similar tests on pulps have only limited and empirical significance in following the course of beating. An explanation is given for the mechanisms of fibrillar reactions, fiber disintegration and the numerous phys. and chem. changes occurring during disintegration of fibers. By inference, true wall laminations would appear to be at least 1 μ thick, and thicker if heavily coated with gel. S. I. Aronovsky

The refractivity of cellulose as a function of the degree of swelling. P. H. Hermans and P. Platzek. *Rec. trav. chim.* **58**, 1001–7(1939)(in German).—The observation made by Meyer and Frey-Wyssling (*C. A.* **30**, 1555[8]) that the n of ramie fibers decreases on swelling in H_2O less than would be expected according to Wiener's theory of mixed substances is reaffirmed by measurements of isotropic fibers of regenerated cellulose for H_2O contents up to 24.4%. In agreement with M. and F.-W. it is concluded that the phys. assumptions of W.'s theory are not fulfilled under all circumstances in the system cellulose–H_2O. Possible explanations for this fact are discussed. With more swollen fibers with a H_2O content of 50% or more, the anomaly ceases, and for such fibers the Newton-Wiener mixt. formula is again valid. F. E. Brauns

Determination of cellulose in plants and bleaching cellulose materials. I. New method of cellulose estimation by bleaching powder. Sin-iti Honda. *J. Agr. Chem. Soc. Japan* **15**, 966–72; *Bull. Agr. Chem. Soc. Japan* **15**, 139–41(in English)(1939).—The wood of *Salix caprea* L. was extd. with alc. and C_6H_6. The residue was boiled with 2% Na_2SO_3 for 10 min., filtered and washed with hot H_2O. It was treated with 5 cc. of bleaching powder contg. 10% of available Cl for 10 min. After filtration and washing, it was again boiled with 2% Na_2SO_3 for 10 min. The chlorination was repeated and it was then treated with acid Na_2SO_3 soln. until the color reactions disappeared. Y. Kihara

Determinations of uronic acids in cellulosic materials. Roy L. Whistler, A. R. Martin and Milton Harris. *Textile Research* **10**, 109–19; *Am. Dyestuff Reptr.* **29**, 1–6; *J Research Natl. Bur. Standards* **24**, 13–25(1940).—Naturally occurring cellulosic fibers appear to be a more or less intimate assocn. of cellulose with other constituents, a portion of which appears to be composed of uronic acids, presumably contained in the pectic substance of the fibers. Treating pure uronic acid with a boiling soln. of HCl results in a steady evolution of CO_2 to completeness whereas pure carbohydrates show a much slower but const. evolution of CO_2 during the entire treatment. This difference in rate of evolution of CO_2 is the basis of a method of detg. uronic acid in the presence of cellulosic materials. The app. is described and illustrated and curves show the rates of evolution in mg. CO_2 per g. for periods up to 8 hrs. from galacturonic acid monohydrate, from glucose, from dewaxed cotton, from a mixt. of glucose and galacturonic acid, from a dewaxed and purified cotton. Tables show the evolution of CO_2 from galacturonic acid, glucose and a mixt. of both and the amt. of CO_2 evolved from the uronic acid groups of ramie and flax fibers. Twenty-one references. W. H. Boynton

Macromolecular compounds. CCXXVIII. The strength of fiber celluloses with different degrees of polymerization. H. Staudinger and J. Jurisch. *Zellwolle, Kunstseide, Seide* **44**, 375–6(1939); cf. *C. A.* **33**, 9291[8].—The relation of fiber strength to degree of polymerization cannot be compared for natural *vs.* artificial fibers, because the structure of the mols. in an artificial fiber varies with the spinning process. Thus a high-mol. cellulose of a mean degree of polymerization of 1000 and a highly degraded cellulose of a degree of 300 cannot be spun under the same conditions. A 0.5% xanthate soln. of the former is approx. as viscous as a 10% spinning soln. of the latter. Strength studies were made on material obtained by degrading, by acid treatment, the cellulose mols. of the natural fibers in the solid state. The strength increases rapidly with increasing degree of polymerization from 200 to 700; a further increase to 1000 increases the strength only slightly; a final increase of the degree of polymerization to 3000 produces practically no further change. Lowering the mean degree below 200 is accompanied by a rapid disintegration of the fiber. The decrease of strength is due to the increased number of intermolecular spaces (of 3-4 A.) in the fiber. To study the relation of mol. size to strength in oxycelluloses, the following natural fibers were oxidized for varying periods with 1% H_2O_2 in 2% NaOH at 50°: (*a*) unbleached ramie fibers that had been purified by extn. with 0.5 *N* NaOH in an atm. of N, (*b*) crude cotton which had been extd. with water, alc. benzene and acetone, (*c*) cotton which had been extd. as under (*b*) and which was purified further by boiling with 1% NaOH in an atm. of N, (*d*) cotton which had been treated as under (*c*) and which was mercerized with 20% NaOH for 20 min. at 20°, (*e*) bleached com. cotton yarn manufd. by Mez, A.-G. The mean degree of polymerization was detd. by viscosity measurements in Schweizer's reagent. Strength of the fiber decreases only slightly as the degree of polymerization decreases from 3000 to 1000; strength decreases rapidly on a further drop in polymerization to 200. If the degree of polymerization decreases below 200 the cellulose disintegrates; these results duplicate those obtained with hydrocelluloses. **CCXXIX. The strength of cellulose nitrate fibers of different degree of polymerization.** *Ibid.* 377–8.—Studies were made on the resistance to tearing in relationship to the degree of polymerization of nitrates of cotton celluloses obtained by oxidative degradation and extn. with org. solvents. The strength of the nitrate fibers decreases with decreasing degree of polymerization; the data are approx. the same as those obtained for the cellulose fibers. Nitration of viscose staple rayon and Cu rayon with a mixt. of HNO_3 and H_3PO_4 gave products of approx. the same strength as the original artificial fibers. L. Scheflan

The strength-stretch diagram of isotropic cellulose fibers in light of the theoretical relation between swelling isotropy, orientation and strength. I. Fibers in different degrees of swelling. P. H. Hermans. *Kolloid-Z.* **89**, 344–8(1939).—If one substitutes for the conventional experimentally detd. stretch value v, the calcd. "characteristic stretch value" v_t, the curves for strength of isotropic fibers of widely different degrees of swelling no longer cross each other aimlessly but form a rational family of curves. The course and position of these curves are satisfactorily explained on a previously developed theoretical relation between swelling anisotropy and strength having also in view the empirically known relation between swelling anisotropy and v_t. The curves are of common significance and have as a parameter the strength at the yield point. **II. Fibers produced by different methods.** P. H. Hermans and P. Platzek. *Ibid.* 349–54.—Expts. were made with three viscoses (figures show %): (1) alkali 5, cellulose 8, normally ripened; (2) alkali 4.5, cellulose 4, ripened less; (3) alkali 4.5, cellulose 2, un-

ripened. From these viscoses isotropic fibers were spun, the conditions of spinning (sol.-gel. transformation) detg. the special form of the characteristic Q-v_i curve, where Q is the swelling anisotropy indicative of orientation. There is impressed upon the gel at the time of its formation a certain deformation behavior, which persists throughout its subsequent swelling history. The course of the empirically detd. strength-stretch curves correspond quantitatively to those theoretically calcd. Cellulose fibers are described, swollen to less than 3% dry substance, which are still stretchable and capable of manipulation, while with certain cellulose hydrate fibers a stretching of 220% was observed. Jerome Alexander 1

The quantitative interpretation of force-extension diagrams of isotropic cellulose threads on the basis of a rational theory of the relation between degree of orientation and force (preliminary communication). P. H. Hermans. *Proc. Acad. Sci. Amsterdam* **42**, 798–807 (1939); cf. *C. A.* **33**, 9626⁴.—It is shown that the force-extension diagrams for swollen cellulose threads bear a direct and unequivocal relationship to the micellar orientation during elongation, as detd. by measurement of swelling anisotropy. By means of the theory previously developed from the microscopic structure of hydrate cellulose gels giving a relationship between degree of orientation, swelling anisotropy and tensile strength, it is even possible to construct theoretically force-extension diagrams of all isotropic threads so far investigated which are in satisfactory agreement with the exptl. diagrams. The conclusion that the force increases in inverse proportion to the square of the sine of the av. micellar angle of orientation is independent of the special assumptions made in developing the above theory. The relation between the swelling anisotropy and the characteristic degree of elongation (based on the dry state) for each existing spinned thread and which relation is independent of the degree of swelling during elongation leads to the conclusion that at the moment of coagulation (sol-gel transition) a definite structure is formed whose characteristic elements responsible for the course of orientation as a function of the elongation remain unaltered during all subsequent swelling and contracting processes. The typical course of orientation for any gel may, however, change with the conditions during gel formation. Mark Plunguian 2 3 4 5 6

Lignin from sorgo residue as a source of plastic material. Ippolito Sorgato. *Ind. saccar. ital.* **32**, 529–34(1939); cf. *C. A.* **33**, 9480¹.—On acidifying the spent alk. lye obtained in the manuf. of cellulose from sorgo bagasse by the soda process lignin is pptd. in a yield of 15% on dry substance. The lignin contains 12% of methoxyl; the yield of lignin can be increased by employing a coagulant, but in that case the content of methoxyl is slightly decreased. Various objects can be molded from the product. O. W. Willcox 7

Pulp man's paradise. Donald D. Bode. *Mfrs. Record* **109**, No. 1, 38, 62(1940).—A description of the use of the Australian pine as a raw material for the manuf. of wood pulp, paper, cellulose plastics, etc. Leopold Scheflan

Wood pulp. C. J. Friedlander. *Wood* **4**, 449(1939).—A brief outline of the processes followed in the production of wood pulp, its uses and the vol. of the production in various countries. Leopold Scheflan 8

Hemicellulose extract of various rayon wood pulps. G. A. Richter, C. H. Goldsmith and K. E. Glidden. *Rayon Textile Monthly* **21**, 26–7(1940).—Hemicellulose ext. as detd. in the viscose rayon industry is a more direct measure of the yield of cellulose, inasmuch as the β-cellulose that is retained undergoes xanthation and appears later as "regenerated" cellulose. Extn. procedure and the analytical method are outlined and results tabulated. Results are summed up as follows: (1) under normal steeping conditions, the hemicellulose ext. of various rayon sulfite pulps was approx. equal to the γ-cellulose content, (2) lower than normal steeping temp. and NaOH concn. increased the ext., (3) under steeping conditions of 18% NaOH soln. and 20° the hemicellulose ext. of various pulps increased in the following order (*a*) high α wood pulp from softwood, (*b*) hardwood sulfite and (*c*) several domestic and foreign softwood sulfites. W. H. B. 9

Burning pulp-mill waste from sulfite mill. Grover Keeth. *Trans. Am. Soc. Mech. Engrs.* **61**, 679–83(1939).—Waste sulfite liquor, contg. approx. as much dissolved org. material as pulp produced, when treated with lime reagent by the three-stage Howard pptn. process, yields (1) from the 1st settling tank an inorg. sludge product contg. Ca sulfite, (2) from the 2nd settling tank a lignin fuel product representing approx. 50% of the solids in the waste sulfite liquor and (3) from the 3rd settling tank a mixt. of org. material and unconsumed lime reagent. The lignin fuel product, as obtained from an Oliver type of rotary vacuum filter, contains 68–70% moisture and is essentially a basic Ca ligninsulfonate. After the moisture content had been reduced to approx. 50% on a special press, the lignin fuel was burned in admixt. with coal (85:15). On the dry basis, the lignin fuel contained C 46.68, H 4.11, O 23.28, S 4.12, N 0.53, ash 21.28% and had a heat value of 8103 B. t. u./lb. George Ayers

Cellophane (Waterfield) **13**. Effect of water-sol. salts on elec. properties of paper boards (Koritskii) **13**. Structure of cellulose (Haworth) **10**. Treatment of waste materials contg. paper (Belg. pat. 432,217) **9**. Printing on pellicles of hydrophilic colloid [cellulose hydrate] (Can. pat. 384,909) **26**.

Cellulose. József Kovách and Sándor Kasser. Hung. 122,064, Nov. 15, 1939. The disintegrated cellulosic substance is treated with 1–8% HNO_3 at not higher than 80° in a closed container under pressure. The fibers are washed and treated in the same app. with a 0.5–4.0% soln. of alkali or alk. earth hydroxides or hypochlorites at 20–100° to dissolve the incrusting substances. The acid and alkaline solns. are led back to the app. as pretreating mediums.

Working up cellulose fibers. Lajos Töreky. Hung. 121,871, Nov. 2, 1939. The disintegrated fibers are mechanically cleaned by air currents, washed with a soln. of NaOH or Na_2CO_3, boiled under 1–3 atm. pressure for 1–1.5 hrs. at 100–120° in solns. contg. either $Ca(HSO_4)_2$, $Ca(HSO_3)_2$ or NaOH. They may also be treated with cold HNO_3.

Cellulose solutions. Charles Graenacher and Richard Sallmann (to Soc. pour l'ind. chim. à Bâle). U. S. 2,179,181, Nov. 7. Oxides of tertiary amines, such as triethylamine oxide, are used in forming solns. of cellulose such as cotton linters which are suitable for prepg. pptd. cellulose.

Regenerated cellulose products such as those from cellulose xanthate. Johann Eggert and Walter Gellendien (to Deutsche Hydrierwerke A.-G.). U. S. 2,179,449, Nov. 7. Regenerated cellulose is used with a strengthening agent such as 2-furaldehyde, methyl-2-furaldehyde, furfuryl alc., methylfurfuryl alc., furfuryl acetate, methylfurfuryl adipic acid ester, furfuryl butyl ether, methylfurfuryl oleyl ether, or methylfurfuryl monoglycerol ether and naphthol, a naphtholsulfonic acid salt or cresol.

Treatment of organic derivatives of cellulose. George Schneider (to Camille Dreyfus). Can. 384,914, Oct. 31, 1939. To reduce its corrosive action and otherwise improve it, an org. deriv. of cellulose is treated while in the secondary soln. with a soln. capable of liberating Cl. E. g., cellulose acetate is treated with 5% of a 12.1% soln. of Ca hypochlorite.

Purifying cellulose ethers. Alexander S. Finlayson (to Hercules Powder Co.). U. S. 2,178,630, Nov. 7. A process for purifying substantially water-insol. cellulose ethers such as cellulose ethyl ether involves treatment in the solid form with an aq. soln. of a lower aliphatic acid such as formic acid contg. about 0.05–0.5% of the acid for a time sufficient to convert the insol. metallic constituents in the cellulose ether to compds. sol. in the dil. acid soln., and then washing with water.

Methyl ethers of cellulose. Robert R. H. Brown and Andrew J. Watters (to Canadian Industries Ltd.). Can. 385,198, Nov. 21, 1939. With cellulose in the presence of

aq. caustic alkali is incorporated an amt. of Me_2SO_4 not more than sufficient to form a methylcellulose contg. about 4–10% methoxyl groups per glucose unit of the cellulose, and the product is treated with a suitable proportion of a lower alkyl chloride.

Cellulose ether carboxylic acids. Julius Voss (to Kalle & Co. A.-G.). U. S. 2,179,457, Nov. 7. One mol. of cellulose such as alkali cellulose is caused to react with about 1–1.5 mols. of a halogenated fatty acid such as monochloracetic acid in the presence of about 3 4 mols. of NaOH and of a chemically indifferent Na salt such as NaCl (suitably at 35–40°) to obtain a product which on acidification with HCl yields pptd. cellulose glycolic acid.

Stabilizing cellulose esters such as cellulose acetate against acid fading when dyed. Herbert E. Martin (to Celanese Corp. of America). U. S. 2,177,903, Oct. 31. For stabilization, an ester such as a cellulose acetate dissolved in the org. acid soln. in which it is formed and which contains S compds., is mixed with Mg acetate, the mixt. is allowed to stand for 3–16 hrs. at 22°, and a diluent such as water is then added and stirred with the mixt. to effect pptn. of the cellulose ester in the presence of the Mg acetate used.

Cellulose esters. Howard S. Gardner, Jr. (to Canadian Kodak Co., Ltd.). Can. 385,316, Nov. 28, 1939. Cellulose is pretreated, without a catalyst, with the acylating acid contg. 5–20% of water, and then esterified.

Noncorrosive cellulose esters. George Schneider (to Camille Dreyfus). Can. 384,915, Oct. 31, 1939. An equal wt. of a weak org. acid is added to a ripened soln. of cellulose ester, the resulting soln. treated with Cl or hypochlorites in an amt. equiv. to 0.02–1% of free Cl based on the wt. of the cellulose ester, and the product treated with an antichlor.

Cellulose acetate pellicles. Ambrose W. Staudt (to E. I. du Pont de Nemours & Co.). Can. 384,434, Oct. 3, 1939. A pellicle is cast from a flowable cellulose acetate compn. contg. a solvent, a moistureproofing agent, a plasticizer and a blending agent comprising at least one of the class consisting of hydrogenated resin, gum elemi, sulfonamide-aldehyde resin, ethylene dibenzoylbenzoate, and lactic acid condensation resin. The greater part of the solvent is evapd. by circulating air at 70° or higher; the film is stripped from the casting surface, and the remainder of the solvent evapd. by circulating air at 80° or higher. An app. is described.

Extrusion apparatus suitable for the manufacture of multi-colored celluloid rods, etc. Camillo Orsini (to Nixon Nitration Works). U. S. 2,171,095, Aug. 29. Various structural details.

Cellulose acetate rayon and other products. Wm. A. Dickie and Percy F. C. Sowter (to Celanese Corp. of America). U. S. 2,178,741, Nov. 7. A process for the manuf. of artificial filaments, threads, yarns, ribbons, etc., comprises extruding a soln. of an org. deriv. of cellulose such as cellulose acetate in a solvent medium such as dioxane, glycol monoacetate or methyl glycol monoacetate through a shaping device into a coagulating liquid contg. a high concn. of the same solvent medium together with a nonsolvent such as water and subjecting the coagulated product to a drying operation (the solvent medium contg. a constituent which is less volatile at the drying temp. than is the nonsolvent mentioned).

Rayon from solutions such as those of viscose. James J. Polak and Johannes G. Weeldenburg (to American Enka Corp.). U. S. 2,179,195, Nov. 7. Filaments or the like are formed by extruding a soln. such as one of viscose through a minute orifice into a coagulating medium, the soln. contg. a dissolved cation-active NH_4 compd. having linked thereto an atomic grouping contg. benzene nuclei inducing cation-activity and an innocuous anion, such as toluene azophenyltrimethylammonium iodide which serves to lessen clogging. U. S. 2,179,196 relates to the manuf. of viscose yarn by extruding a viscose soln. through a minute orifice into a pptg. bath contg. a cation-active tetraalkylammonium salt such as dodecyltriethylammonium sulfate or the like and which serves to prevent or lessen clogging. Cf. *C. A.* **33**, 3588[1].

Sulfite digestion of cellulose. Torsten E. Waenerlund (to Mo och Domsjö Aktiebolag). U. S. reissue 21,251, Oct. 31. A reissue of original patent no. 1,809,499 (*C. A.* **25**, 4708).

Machine for defibering pulp. Joseph E. Bond. Can. 384,499, Oct. 10, 1939. Structural details.

Bleaching fibrous materials such as wood pulp or textile materials. Irving E. Muskat and George H. Cady (to Pittsburgh Plate Glass Co.). U. S. 2,178,696, Nov. 7. Bleaching is effected with a soln. of HOCl prepd. by treating water with Cl_2O which is substantially free of HCl, ClO_2 and oxides of N.

Bleaching wood pulp. John Schuber (to Solvay Process Co.). U. S. 2,178,649, Nov. 7. In treating an aq. pulp suspension with a Cl bleach soln., a pH of 8.3–10 is maintained during the treatment until the bleach has been substantially exhausted, and the alky. of the mixt. is then increased.

Treating sulfite pulp residual liquor. Geo. H. Tomlinson and Leslie S. Wilcoxson (Wilcoxson to Babcock & Wilcox Co.). U. S. 2,179,456, Nov. 7. App. is described, and a process of treating sulfite pulp residual liquor which involves burning it in a furnace under conditions yielding a dry noncombustible ash residue, removing substantially all of the ash produced from the furnace by flotation in the heating gases, and sepg. the ash from the gases after leaving the furnace.

Machine for refining paper pulp. Joseph E. Bond. Can. 384,500, Oct. 10, 1939. Structural details.

Semipulp from straw. Umberto Pomilio (to Pomilio Corp. Ltd.). U. S. 2,178,266, Oct. 31. An arrangement of app. is described, and a continuous process for the manuf. of semipulp from straw which consists in mixing the straw with an alkali soln. of 1% strength and in proportions of 1 part of straw to 3 parts of the soln., traversing the mixt. through a reaction tower raised to a temp. between 75° and 100° at such a rate that the material remains in the tower from 1 to 4 hrs., transferring the material to a vessel where it is washed with water, dewatering the material and introducing it with Cl dild. with air in proportions of 0.5 to 1 part by vol. of air to 1 part by vol. of Cl and in quantities such that there are 4 to 5 parts of Cl introduced to 100 parts of straw, traversing the material at such a rate that it remains in the reaction vessel 0.5–3 hrs., immersing the material, immediately after leaving the last vessel, in a cold water bath, transferring the material from the bath to another vessel and treating it with an alkali soln. of a strength of 0.1% and in quantities from 5 to 20 parts of soln. to 1 part of the vegetable material.

Recovery of lime sludge such as that from pulping wood. Herman L. Joachim. U. S. 2,178,586, Nov. 7. An arrangement of app. is described, and a process involving CaO production by calcining a wet $CaCO_3$ sludge contg. about 50% water, which involves adding about 10% of CaO to the wet sludge, to effect bulking and preheating by hydration of the CaO by the wet sludge.

Nitration of pulp sheets. Milton O. Schur (to Brown Co.). Can. 384,858, Oct. 31, 1939. Wood pulp for esterification is formed into lengths by chipping from a sheet of felted wood pulp, the lengths being thinner than the sheet from which they are chipped.

Paper. Joseph E. Plumstead (to Raffold Process Corp.). U. S. 2,178,606, Nov. 7. A process for the manuf. of paper having a carbonate filler such as $CaCO_3$ involves causing Cu sulfate, chloride, nitrate or acetate to react with a carbonate such as $CaCO_3$ and $MgCO_3$ in the presence of water and mixing the resulting product with fibrous material.

Paper. Kenneth W. Britt (to Scott Paper Co.). Can. 385,773, Dec. 19, 1939. The wet strength of paper is increased without materially affecting the normal physical characteristics of the sheet by introducing into the sheet in aq. soln. a synthetic resin in amt. not more than 5% by wt. of the fibers, drying the sheet at low temp. prior to conversion of the resin to the insol. state to a point where any residual liquid is confined substantially to the cellulosic structure of the fibers. Cf. *C. A.* **33**, 7567[1].

Self-cleaning screen plate for papermaking machine. Henry W. Downs, Jr. (to Union Screen Plate Co. of Canada, Ltd.). Can. 385,019, Nov. 7, 1939. Structural details.

Stock regulator for paper machines. Ernest Poirier. Can. 384,658, Oct. 17, 1939. A stream of paper stock is continuously flowed through a container under substantially const. head with resistance to flow opposed so that the stock level will drop with a rise in consistency and rise with a decrease in consistency, dilg. water is mixed with the stream of stock at a point immediately preceding the inlet to the container, and the hydrostatic head of stock in the container is caused to control the vol. of dilg. water added.

Screening mechanism for paper stock. Charles J. Lindequist (to Bird Machine Co.). Can. 385,314, Nov. 28, 1939. Structural details.

Stock-treating member for paper-stock machines. Harold D. Stuck (to John W. Bolton & Sons, Inc.). Can. 384,853, Oct. 31, 1939. The stock-treating member in a beater or a Jordan engine consists of a ferrous body with recesses in the upper parts of its front and back faces filled with a layer of nonferrous, acid-resisting metal hot-welded and compacted with the body to form an integral bar.

Drier felt for paper machines. William A. Barrell (to Lawrence Duck Co.). Can. 384,295, Sept. 26, 1939. Structural details.

Fourdrinier machine. Joseph H. Castonguay. Can. 384,361, Oct. 3, 1939. The delivery of stock onto the forming wire is controlled by directing compressed air against the stream of stock leaving the slice orifice to cause the stream to strike the wire at a tangent. An app. is described.

Steam-heated drier drums for use in paper manufacture, etc. Earl E. Berry and Lloyd Hornbostel (to Beloit Iron Works). U. S. 2,173,225, Sept. 19. Various structural and operative details involving cooling of the drum bearings by circulation of air.

Testing the folding endurance of paper and like materials. James d'A. Clark. U. S. 2,179,116, Nov. 7. App. is described, and a method of testing the folding endurance of a strip of material which consists in folding it double about a line across its width; squeezing the strip together at the folded edge; unfolding the strip and subjecting its ends to a predetermined tension, then folding the strip double in the reverse way to the previous fold about the same line, reapplying the squeezing pressure; unfolding the strip, reapplying the tension and continuing these steps successively until the strip breaks and recording the number of double folds so made before fracture.

24—EXPLOSIVES AND EXPLOSIONS

C. G. STORM

Recent developments in explosives. C. L. Barker. *Mines Mag.* (Colo. School of Mines) **29**, 611–12, 628, 632 (1939). Leopold Scheflan

Drying of Powder B. Influence of the surface film. R. Dalbert. *Mém. poudres* **29**, 69–75(1939).—Powders dried at 60 and 80° were removed at intervals of 14, 24, 48 and 72 hrs., the surface was filed off to a depth of 0.3–0.4 mm. and heating continued to det. the ratio of the rate of drying before and after scraping. Results showed that there was a marked difference in compn. of the internal and surface solvent. Et_2O does not diffuse through the grain or the surface film as rapidly as EtOH and is held back. H_2O is also held back in the residual EtOH. A. J. Phillips

Distribution of solvent through Powder B. H. Lacape and Ficheroulle. *Mém. poudres* **29**, 76–84(1939).—Three successively increasing thicknesses were removed from the periphery and ends of cylindrical grains of powder and the samples were exposed to various conditions of soaking and drying and tested for coeff. of elimination (loss of weight on heating for 4 hrs. at 108.5°) and coeff. of emission (loss of wt. after heating for 16 addnl. hrs. at 108.5°). The coeff. of elimination was highest for the central portion of the cylinders and it is indicated that there is less solvent in the external layer than in the center of the powder and that the external layers part with solvent less readily than the central portion. A. J. Phillips

Residual solvent of Powder B. H. Lacape and Ficheroulle. *Mém. poudres* **29**, 85–94(1939).—Powders contg. 1.15% of initial solvent of varying proportions of EtOH and Et_2O were dried at 45° in air of humidities varying from 0.4 to 0.9. Neither the hygroscopic condition of the air nor the compn. of the initial solvent influenced the rate of drying. Varying hygroscopicity had no influence on the compn. of the residual solvent, nor was evapn. retarded when drying was carried out in an atm. of EtOH. A. J. Phillips

Notes on the elimination of solvent from Powder B. L. Solier. *Mém. poudres* **29**, 49–68(1939).—Soaking of powders in satd. $CaCl_2$, C_6H_6, $LiCl_2$ and ligroin gave in the first two cases very translucent powders but in all cases the coeff. of emission was high owing to surface hardening of the powder by too rapid elimination of solvent. To reduce this effect, samples of BG_4 powder were soaked for 1–12 days in EtOH (80°, 60°, 40°, 20°) and then for 5, 12 and 20 days in H_2O at 30°. It was found that the coeff. of emission was not an accurate index of the residual solvent in the powder and the loss of weight in drying was due chiefly to EtOH. The heat test at 108.5° varied proportionally with the amt. of residual solvent. The percentage of residual solvent increases with decrease in the strength of alc., while the stronger the alc., the greater the opacity and the lower the stability. Steeping in H_2O without previous EtOH treatment showed poor elimination of Et_2O. Much better results with respect to coeff. of emission and stability were secured on high volatile powders when 1–10% Et_2O was added to the EtOH, followed by steeping in pure H_2O. Steeping in EtOH at 60° produced as rapid results as MeOH at 30°. Good results were secured with powders contg. centralite, while powders contg. diphenylamine turned blue. Soaking in hot H_2O resulted in a new hardening of the surface with retention of volatile solvent. A. J. Phillips

Gelatinization of nitrocellulose by mineral acid esters. L. Medard. *Mém. poudres* **29**, 10–11(1939).—Me_3BO_3, $PrNO_3$, $BuNO_3$ and $PrNO_3$ have no gelatinizing action on nitrocellulose. Me_2SO_4 and 80–20 $EtNO_3$-EtOH gelatinize collodion and pyrocotton but guncotton is incompletely affected. Nitroglycerin acts slowly in the cold but at 100° there was complete gelatinization in 4 hrs. Me_3PO_4 and Me_2SO_3 gelatinize the 3 different cottons, rapidly and completely. A. J. Phillips

Raman-effect investigations on oleums and sulfonitric acid mixtures. J. Chédin. *Mém. poudres* **28**, 7–42(1938).—From studies of individual constituents and mixts. of HNO_3, H_2SO_4, H_2O, P_2O_5 and N_2O_5, it is concluded that the amt. of HNO_3 in sulfonitric acid mixts. is the factor which dets. the degree of nitration of both cotton and toluene. Cf. Berl, Andress and Escales, *C. A.* **33**, 9069[4]. A. J. Phillips

Explosibility of aluminum powder-silica dust clouds. Ralph B. Mason and Cyril S. Taylor. *Ind. Eng. Chem.* **32**, 67–8(1940).—In connection with the use of Al powder as an agent for the prevention of silicosis (*C. A.* **31**, 6369[5]), the effect of silica dust on the explosibility of SiO_2-Al dust clouds in air was studied. The method of test and fineness of Al were the same as in a previous study of Al dust (*C. A.* **31**, 5582[2]). When the SiO_2 content was twice the concn. of the Al, no explosion resulted. The effect is similar to that of rock dust in preventing coal dust explosions. C. G. Storm

The prevention of anesthetic explosions. Warren P. Morrill. *Bull. Am. Assoc. Nurse Anesthetists* **7**, 308–9 (1939).—The causes for 102 fires and explosions with

gaseous anesthetics are analyzed and practical suggestions given for preventing these in the operating room. J. Pinchack

The proper control and best methods of venting dust explosions in industrial plants. Hylton R. Brown. *Fire Eng.* **92**, 534–7(1939); cf. *C. A.* **33**, 8655.—Observations made at industrial plants in the U. S. after dust explosions have indicated that it is impractical to build walls strong enough to withstand the pressures produced. The losses from dust explosions are heavy even in modern, well-equipped and efficiently operated industrial plants. Methods of preventing such explosions are described. Tables show the explosion pressure necessary to break different grades of glass. The Am. Standard safety code for the prevention of dust explosions in industry is given and the need for further studies is pointed out. L. S

Two illuminating-gas explosions. Holsten. *Feuerschutz* **19**, 135–9(1939).—The causes of gas explosions in an apartment house and in a factory building are discussed in detail and government regulations for preventing similar accidents are recommended. Leopold Scheflan

Cooling effect of the walls (of a closed bomb) in explosion of mixtures of (colloidal) powders. H. Muraour. *Mém. artillerie franç.* **17**, 835–7(1938); cf. *Ibid.* 381 (1930).—The area under the pressure-time curve, $\int p\,dt$, for thick powders of given compn. is independent of total time of combustion. For a mixt. of different-size grains this area is characteristic of the slower burning (thicker) granulation, but the quickness and temp. of explosion tend to characterize the faster granulation. Thus $\int p\,dt$ is proportional to the total no. of mol. impacts. But loss of heat to the walls of the bomb depends not only on no. of mol. impacts but also on the time factor. Various mixts. were fired in bombs of different sizes and surface areas, to study the relation between max. pressure and the ratio of surface to bomb vol. (S/V). The slopes of the resulting curves for the various mixts. differ only slightly—except that one curve (100% fast powder) has much less slope than the others. Here the shortened time minimizes the loss of heat to the walls. B. E. Anderson

The combustibility and smoldering property of artificial leather and shoe tip fabrics made from nitrocellulose. L. Metz and H. Hauske. *Feuerschutz* **19**, 120–3, 132–5 (1939).—The results of lab. and large-scale tests are described, the fire and explosion hazards are discussed and German government regulations on manufg. operations are given. Leopold Scheflan

How fires start and how they burn. David J. Price. *Fire Eng.* **93**, 8–11(1940).—A discussion of the principles of combustion and hazards from CO. Leopold Scheflan

---

pH and stability of colloidal powders (Rouvillois) 2. Lecture demonstrations [on fires, extinguishing of fire and on spontaneous combustion] (Greenwood) 2.

Explosives. Willard de C. Crater (to Hercules Powder Co.). U. S. 2,179,323, Nov. 7. By the nitration of a mixt. of a carbohydrate such as sugar, glycerol and α-methyl glycerol, an explosive is produced.

Explosives. Joseph Simon (50% to Daniel Hewitt). U. S. 2,179,434, Nov. 7. An incompletely charred cotton treated with HNO_3 and H_2SO_4 to effect nitration is used with other materials such as KNO_3, $NaNO_3$ and S to form explosives.

Explosive. Harrison H. Holmes (to E. I. du Pont de Nemours & Co.). Can. 384,570, Oct. 10, 1939. A deflagrating explosive in pellet form consists of a mixt. of 15–45% NH_4NO_3 with black powder and at least one finely divided metal, e. g., Al, capable of undergoing rapid combustion at temps. normally occurring during the combustion of black powder.

Smokeless powder. Ellsworth S. Goodyear (to Hercules Powder Co.). U. S. 2,179,330, Nov. 7. A method of prepn. of progressive-burning, double-base smokeless powder, producing breech pressures when fired at sub-zero temps. which are not substantially greater than those produced when fired at ordinary temps., involves coating double-base smokeless powder grains at a temp. less than about 55° (suitably about 10–50°) with an admixt. of a nonvolatile, nonexplosive org. material such as butyl-acetyl ricinoleate which is a nonsolvent for the nitrocellulose but compatible therewith, and a solvent for the nitrocellulose, such as ethyl *o*-benzoylbenzoate, and rosin. Cf. *C. A.* **33**, 4040[4].

Progressive-burning smokeless powder. Elton R. Allison (to Hercules Powder Co.). U. S. 2,179,312, Nov. 7. Smokeless powder grains are coated with a lower alkyl ester, such as the methyl ester, of *o*-benzoylbenzoic acid m. 35–110°. U. S. 2,179,313 relates to the like use of coatings of similar m. p. range and comprising phenyl benzoate or other aryl ester of benzoic acid, or of a lower fatty acid such as β-naphthyl acetate. U. S. 2,179,314 relates to like use of coumarin as a coating. U. S. 2,179,315 relates to coatings of progressive-burning powder comprising a petroleum hydrocarbon-insol. resin derived from pine wood.

Match composition. János Pfeiffer and Gyula Büti. Hung. 122,094, Nov. 15, 1939. Ferrous lactate and $FeSO_4$, are dissolved in water, filtered, cooled and $KClO_3$ is added. Dextrose charred by heating to 150–200° added to the soln. Finally the mixt. is made up to a pulp with glue and starch.

Treating aluminum foil sheets for photoflash lamps. Harry W. Highriter (to Westinghouse Elec. & Mfg. Co.). U. S. 2,177,108, Oct. 24. Uniformity of the rate of combustion is improved by heating the foil to 150–500° for about an hr. or less (the time varying in inverse relation to the temp.).

25—DYES AND TEXTILE CHEMISTRY

L. A. OLNEY

The use of semiwool metachrome dyes. Richard Kahl. *Monatschr. Textil-Ind.* **54**, 234–6(1939).—Chem. and mech. treatments are discussed in detail and four samples of dyed fabrics are shown. Leopold Scheflan

Black dye of the Navajos. Daniel T. O'Connell. *Science* **90**, 272(1939).—Carnotite is roasted in a pan over an open fire until its color changes from yellow to black. In a similar manner the pitch from pinyon trees (stunted pines) is heated until it becomes brittle and breaks into a black powder. The 2 powders are mixed and stirred into a soln. formed by boiling the entire plant of the squawberry bush (*Rhus trilobata*) in H_2O until the liquid assumes the color of tea. In a Navajo rug black-dyed wool was used in combination with wool colored with dyes prepd. from the roots of various plants. L. Wilson Greene

Use of alginic acid in the manufacture of printing colors. V. I. Butin and V. V. Tavrovskaya. *Khlopchato-Bumashnaya Prom.* **1939**, No. 6, 48–9.—Expts. have shown that alginic acid can be used partly or completely as a substitute for gum and tragacanth in the prepn. of printing colors. The acid can also be used partly as a substitute for starch except in cases where a color of special density is desired. The characteristics of various colors prepd. with alginic acid are described. B. Z. Kamich

Matching colors. C. H. S. Tupholme. *Textile J. Australia* **14**, 173–4(1939).—A description of the use of a color comparator for the measurement of colors in the textile industry. Leopold Scheflan

Scientific management and the dyehouse. John P. Redston. *Can. Textile J.* **56**, No. 22, 33–5(1939). Leopold Scheflan

Temperature control in the dyehouse. Frank S. Ward. *Can. Textile J.* **56**, No. 24, 39–42(1939).—An illustrated discussion of the importance of controlling related processes and applications in woolen and worsted manuf. Leopold Scheflan

The protection of the textile fiber during dyeing and dye stripping. W. Pflumm. *Spinner u. Weber* 57, No. 43, 70, 72(1939).—A discussion of appropriate chem. treatments. Leopold Scheflan

The dyeing of wool and of a mixture of wool and staple rayon with Naphthol AS dyes. H. Rath and P. Kubitzky. *Klepzig's Textil-Z.* 42, 632–4(1939).—To decrease the hazard of alk. damage during dyeing, an attempt was made to increase the water soly. of Naphthol AS by introducing a hydroxymethyl group into the α-position next to the β-OH. If the dyeing conditions are observed properly this deriv. is absorbed evenly by the fiber and reacts with diazotized bases and dye salts. The effect produced with wool is usually more yellowish than that obtained with staple rayon. The resistance to scouring of the dyed textile is not very high. Leopold Scheflan

The vat dyeing of wool. Frische. *Deut. Wollen-Gewerbe* 71, 1234–6(1939).—A discussion of chem. and mech. treatments. Leopold Scheflan

The protection of wool during redyeing. W. Pflumm. *Klepzig's Textil-Z.* 42, 684–5(1939).—The removal of dyeings is discussed. Good protective agents are proteins related to those in wool (e. g., bone glue), protein degradation products, sulfite liquors of the type used in mordant treatments and Cr dyeings, and "Modinal." The latter product has good leveling and reviving properties and improves the phys. qualities of wool. Three photomicrographs are shown. Leopold Scheflan

Dyeing tropical suitings. N. E. Scafe. *Textile J. Australia* 14, 180(1939).—In many cases fading arises from the fact that unsuitable tinting colors are used for sightening purposes and since they are not removed during the processing of the cloth, a residue of fugitive color, which remains incorporated in the dyed shade, vitiates its fastness. The suitability of any form of coloring matter for tinting sightening yarns depends primarily on the ease of its removal from the cloth during the ordinary processes of dyeing and finishing. This removal may be brought about when the coloring matter (1) is simply washed out of the cloth by friction during the scouring of the pieces, (2) is destroyed or decolorized by the alky. of the scouring bath or (3) is partly removed by being dissolved out of the cloth by the acid used in dyeing. Leopold Scheflan

Certain difficulties in the weaving and dyeing of silk and acetate rayon. W. Weltzien. *Zellwolle, Kunstseide, Seide* 44, 378–81(1939).—A detailed discussion of processing difficulties in strand-dyed Organzin as well as in the degumming of silk in the presence of acetate rayon. Chem. and mech. methods of overcoming these difficulties are described. Leopold Scheflan

Review of the newest and most modern advancements in the dyeing of artificial and mixed fibers. Carl-Heinz Fischer. *Deut. Wollen-Gewerbe* 71, 1205–7(1939). Leopold Scheflan

The practice of the dyeing of staple rayon and staple rayon mixtures. Wilhelm Kegel. *Deut. Textilwirt.* 6, No. 21, 29(1939); cf. *C. A.* 33, 8691.—As it is necessary to know what grade of staple rayon is present in a given product previous to dyeing operations methods for making such detns. are explained. Leopold Scheflan

Dyeing and finishing staple rayon and mixture fabrics. Harold DeWitt Smith. *Can. Textile J.* 57, No. 2, 27–8, 38(1940).—An address. Leopold Scheflan

The cause of irregular and streaky dyeing in the use of naphthol AS on rayon, staple rayon and their mixtures with cotton as well as the prevention of such defects. Frische. *Deut. Wollen-Gewerbe* 71, 1374–5, 1412–13(1939).—The occurrence of unsatisfactory dyeings is due to improper procedures. Correct treatments are discussed in detail. Leopold Scheflan

Dyeings that rub off during wear; cause and prevention. G. Nitschke. *Monatschr. Textil-Ind.* 54, 217–18, 233 (1939).—Poor results are due to faulty treatments or the use of improper dyes or other chemicals. Various remedies are recommended. Leopold Scheflan

Machinery for dyeing cellulose fibers. I. Ormond W. Clark. *Can. Textile J.* 56, No. 26, 35–6(1939); *Textile Bull.* 57, No. 10, 16, 18, 38–9; No, 11, 5–6(1940).—A discussion of the factors influencing the design, selection, operation and maintenance of the machinery used in the application of fast dyes to cellulose fibers as applied to the dyeing of raw stock, skein yarn, package yarn and warp yarn. **II.** *Ibid.* 57, No. 2, 34–7(1940).—A description of features of the modern dye jig, the pad dyeing process, fundamentals of modern padder design, the use of stainless-steel dye tanks, the prevention of creasing of fabric during dyeing and examples of modern continuous dyeing. Leopold Scheflan

Stencils and lacquers in film printing operations. Albert Franken. *Klepzig's Textil-Z.* 42, 589–90(1939).—A description of applications in the textile industry. Leopold Scheflan

The printing of shirting and its development. F. Ettel. *Melliand Textilber.* 20, 811–12(1939).—The widespread success of printing in the manuf. of shirting is based on the use of very fast dyes (Indanthrene fastness) and various mech. devices and processes which are reviewed. J. W. Perry

Progress of the textile industry. A. Foulon. *Deut. Textilwirt.* 6, No. 18, 6, 8(1939).—A review of recent developments in the German textile industry. L. S.

Important chemical developments in the textile industry. E. W. K. Schwarz. *Am. Dyestuff Reptr.* 29, 6–8, 19–21 (1940).—A review emphasizing the important place synthetic fibers have taken in the immediate past. W. H. B.

The refinement of textiles in science and industry. A. Foulon. *Deut. Textilwirt.* 6, No. 20, 16(1939).—A brief survey covering various chem. treatments. L. S.

Nomograms for various plant and laboratory computations. Leonard Shapiro. *Am. Dyestuff Reptr.* 29, 14–18 (1940).—Seven nomograms are given, resp., for: (1) vol. of cylindrical tanks, (2) conversion of yds. per lb. to oz. per sq. yd., (3) correction of yarn or fabric strength to 7.5% regain, (4) correction of fabric strength to 7.5% regain, (5) interconversion of yarn nos., (6) conversion of yarn nos. to the denier system and (7) interconversion of d. scales. W. H. Boynton

The new fibers. F. Bonnet. *Can. Textile J.* 56, No. 24, 43–5(1939).—A survey of recent developments in the manuf. of strong rayon, staple fiber, casein, nylon and vinyon in the textile field. Leopold Scheflan

The chemical technology of the retting of jute. Bernhard Kneer. *Klepzig's Textil-Z.* 42, 643–6(1939).—A detailed description of chem. and mech. com. treatments. The retting bath contains usually mineral oil 10–12%, train oil 6–8%, soap 0.6–0.8%, soda 0.15% and water 79–82%. Leopold Scheflan

A simple scheme for the examination of textile fibers in finishing plants. W. Schönberger. *Klepzig's Textil-Z.* 42, 751–4(1939).—For the alk. plumbite test, heat 5 cc. of 10% Pb acetate soln. with 10 cc. of 5% NaOH until the mixt. is clear and dil. with distd. water to 150 cc.; place the sample for no more than 5 min. in the reagent (temp. 80–90°) and rinse with dil. NaOH, distd. water, dil. AcOH and again with water. For the Neocarmin W test, use the com. product manufd. by Felix Sager & Dr. Gossler G. m. b. H., Heidelberg; immerse the sample for 3–5 min. and rinse with water, very dil. NH_3 and again with water. With Neocarmin B of Felix Sager & Dr. Gossler G. m. b. H., dye cold for 10 min. and rinse thoroughly with water. With 0.2 g. Alizarin Saphirol B and 1 cc. concd. H_2SO_4 per l., dye in boiling soln. for 2 min. and rinse with water. With 0.2 g. Alizarin Saphirol B and 10 cc. concd. NH_4OH per l., dye in boiling soln. for 2 min. and rinse with water. For Millon's test dissolve 1 cc. Hg in 9 cc. HNO_3 (d. 1.5) and add 10 cc. of water; pour the reagent over the original sample and observe sample and soln. 1–2 hrs. later. In a soln. of 10 g. $CuSO_4$ per 100 cc. water, immerse the sample for 10 min. and rinse thoroughly with running water. In 10 g. of $K_4Fe(CN)_6$ per 100 cc. water, immerse the sample (pretreated with $CuSO_4$ soln. and rinsed with water) for 10 min. (*A*) On treatment with alk. plumbite soln. white or light brown shows wool absent; light brown indicates casein fiber or insufficiently desulfured viscose rayon. Use original samples for subsequent treatments as

given under *B* and *C*. Black or brownish black and white or light brown shows that wool and other fibers are present. Use only samples that had been pretreated with the alk. plumbite soln. for subsequent treatments as given under *B* and *C*. Black or brownish black shows pure wool. (*B*) On treatment with Neocarmin W, pure yellow shows casein fiber, yellow tinged with green shows acetate rayon, antique gold shows degummed natural silk, greenish black shows natural silk (not degummed), yellowish olive, greenish olive and green show rayon or staple rayon that had been crease-proofed with urea-HCHO, absence of dyeing shows artificial resin fibers, polystyrene or polyvinyl chloride fibers, blue and blue-violet show Cu (Bemberg) rayon, Lanusa, Schwarza staple rayon, cotton, linen or ramie ((*a*) treatment of original samples with Neocarmin B giving light reddish violet shows cotton, dirty, deep reddish violet shows hemp, clear deep violet shows ramie, deep blue to violet-blue shows linen, Cu (Bemberg) rayon, Lanusa, or Schwarza. Strength of the material when wet indicates linen; (*b*) treatment of fresh samples with $CuSO_4$, $K_4Fe(CN)_6$ giving colorless to faintly pink shows cotton, Cu (Bemberg) rayon, Lanusa or Schwarza, red to deep red shows ramie, linen, hemp), violet or red-violet with Neocarmin B indicates viscose rayon, staple rayon or acid-dyed animalized staple rayon of the viscose type, yellowish olive or dirty yellow indicates casein fiber, yellowish green shows acetate rayon, brown to violet-brown shows natural silk, degummed or not degummed. (*C*) On treatment of original samples with Alizarin Saphirol B and comparison with wool and cotton as indicators, little or no dyeing in ammoniacal or acid soln. shows pure cellulose fibers, more distinct dyeing in acid soln. than in alk. soln. shows animalized staple rayons, Cisalfa (dyed very much less than wool), Fibramin and Artilana (dyed somewhat less than wool) and Vistralan (dyed deeper than wool). (*D*) On treatment of original samples with Millon's reagent, a soln. colorless to faintly yellow and fiber clear pink in 1 min. show Cisalfa, soln. colorless to faintly yellow and fiber clear red in 1-2 min. show Fibramin, soln. reddish orange in 20 min., becoming reddish on standing, and fiber turning slowly brown to brownish red show Artilana, soln. and fiber turning rapidly deep yellow show Vistralan. (Special test for Vistralan: Treat with HNO_3 (d. 1.39) and water (1.1); fiber becomes green in 2 hrs.). Addnl. confirmatory tests are suggested. L. S.

The alkali-solubility of viscose fibers in relation to stretching. P. Eckert, H. Riedel and E. Eder. *Zellwolle u. Deut. Kunstseiden-Ztg.* **5**, 275–7(1939).—The soly. of the fibers in 10% NaOH by wt. decreases with increasing pre-ripeness (alkali cellulose) and increasing after-ripeness (viscose) and stretching. The strength is decreased by prolonged pre- and after-ripeness and is increased by suitable stretching. These relationships are the reverse for elongation. Leopold Scheflan

A simple, rapid method for the quantitative separation of artificial hydrocellulose fibers and native cellulose fibers. Karl Schwertassek. *Melliand Textilber.* **20**, 797–800 (1939).—See *C. A.* **34**, 1171[2]. J. W. Perry

The ratio acid fiber. Carl-Heinz Fischer. *Deut. Wollen-Gewerbe* **71**, 1270–1, 1294–6(1939).—The reaction mechanism occurring during acid treatments of wool and staple-rayon fibers is discussed. During the treatment of a mixt. of the 2 fibers, a certain portion of the acid is absorbed by the wool; this lessens the hazard to the staple rayon constituent. However, there is no definite safe ratio between acid and mixed fibers. In all cases the amt. of the wool constituent is the decisive factor; the abs. amt. of acid to be used in dyeing operations and the latter increases with increasing wool concn. in the mixt. For pure staple rayon there is likewise no definite fixed safe ratio between acid and textile and as long as any acid remains in this textile it may cause damage; this is also true for the staple-rayon constituent in mixts. It is concluded that after completed refinement all woolen goods contg. staple rayon must be freed from residual acids so that the dyed goods, after wetting, show no pH values below 7.0. Leopold Scheflan

The importance of iron soaps for the autoxidation of fatty acids on the (textile) fiber. Kehren. *Melliand Textilber.* **20**, 807–11(1939); cf. *C. A.* **33**, 6058[6], 7118[3].—Expts. with a Mackey tester operated at various temps. from 55° to 89° showed that Fe soaps catalyze the oxidation of oleins free from highly unsatd. fatty components only at temps. above 85°. Only slight temp. rise was observed within shoddy samples impregnated with such oleins contg. Fe soaps and stored in a thermostat kept at 50–52°. Evidently dangers due to the mere presence of Fe soaps in oleins not contg. highly unsatd. components has been greatly overestd. J. W. Perry

Tensile strength of yarns. P. Larose. *Can. Textile J.* **56**, No. 23, 31–3; No. 25, 34–5, 44(1939); cf. *C. A.* **33**, 6055[9].—A discussion of the utilization of fiber strength, friction related to strength, fiber length and diam., effect of increasing twist, increased strength through doubling, irregularity of fiber qualities and distribution, reduction of strength by irregularity of twist and factors which enter in the detn. of fiber strength. Leopold Scheflan

Twist determination in single yarns. H. R. Bellinson. *Textile Research* **10**, 120–6(1940).—Twist in single yarns is detd. by untwisting and retwisting to the same twist in the opposite direction. The instrument used with a twist counter, and indicating the end point by measuring length, consists of a pendulum operating in conjunction with a photronic cell with the end point signalized by a buzzer. W. H. Boynton

Textile fiber atlas. I. Wool. Werner Von Bergen. *Rayon Textile Monthly* **21**, 17–20(1940).—This, the 1st installment of a series covering the various textile fibers, outlines the structure and properties of wool. Several photomicrographs of different qualities and parts of the wool fiber are included. W. H. Boynton

Electrophoretic studies of wool. Arnold M. Sookne and Milton Harris. *J. Research Natl. Bur. Standards* **23**, 471–7(1939)(Research Paper No. 1245).—See *C. A.* **33**, 9654[2]. Milton Harris

The chlorination of wool. Hans J. Henk. *Deut. Wollen-Gewerbe* **71**, 1129, 1132(1939).—The chem. reactions taking place during the chlorination are reviewed and disadvantages of chlorinating with HClO are discussed. Bromination is less harmful to wool than chlorination but is not generally applicable, owing to the cost of Br. The bromoamines formed during bromination are more stable than the corresponding Cl compds. Brominated wool is softer than chlorinated wool and its soly. in dil. acids, alkalies and salt solns. is lower. Shrinking is minimized to the same extent with both halogens. The use of halogens can be avoided entirely by pptn. of $Al(OH)_3$, TiO_2 or gelatin tannate in the fiber or by treatment with HCHO, CH_3CHO or acrolein. However, these treatments have not yet been developed satisfactorily for use on a com. scale. L. S.

Carbonizing wool piece goods. Robert R. Sleeper. *Can. Textile J.* **56**, No. 26, 39–40(1939).—A discussion of the H_2SO_4, $AlCl_3$ and gaseous HCl processes. L. S.

Changes in wool-scouring practice. H. Robinson. *Textile Recorder* **57**, 25–6(Dec., 1939).—A tech. description of the mech. and phys. treatments involved and of the types and strengths of the scouring solns. used. W. H. Boynton

The use of fat solvents in the washing of wool. A. Foulon. *Monatschr. Textil-Ind.* **54**, 247–8(1939); cf. *C. A.* **33**, 9654[6].—The best com. product recommended by F. for this purpose is Sulfinol L. Its use is discussed in detail. Leopold Scheflan

The moisture regain of acetylated silk fibroin. Edward Carr. *Textile Research* **10**, 126–30(1940).—Moisture regain measurements made, at 25° and 79.3% relative humidity, on non-acetylated and on acetylated fibroin show that the equil. moisture content of acetylated fibroin is slightly lower than that of non-acetylated fibroin and varies with the degree of acetylation. In the case of fibers acetylated by means of Ac_2O the decrease in moisture content is not attributable to the action of liberated AcOH. W. H. Boynton

Fermentation degumming of waste silk. V. Useful thermophilic bacteria for fermentation degumming. Hideo Katagiri and Tosio Nakahama. *J. Agr. Chem. Soc.*

Japan **15**, 1042-4; *Bull. Agr. Chem. Soc. Japan* **15**, 144 (in English) (1939).—Twelve strains of thermophilic bacteria were isolated from the degumming liquid at 55°. An aerobic bacillus having a strong degumming action for raw silk was discovered. It may belong to *Bacillus robustus* Blau. Degummase was easily dissolved out into the culture soln. after fermentation for 5 days. Cf. *C. A.* **32**, 7272⁴. Y. K.

Survey of leading American rayon staple fibers. H. R. Mauersberger. *Rayon Textile Monthly* **21**, 29–30(1940). —American rayon staple fibers are tabulated by companies. W. H. Boynton

Supplement to the article: Review of modern refinement of rayon and staple rayon. Max Peter. *Klepzig's Textil-Z.* **42**, 651(1939); cf. *C. A.* **34**, 1182⁹. L. S.

Determination of viscose rayon. R. W. McKay. *Am. Dyestuff Reptr.* **29**, 25–8(1940).—The amt. of viscose rayon in mixts. of viscose with cotton, wool or silk is detd. by a method depending on the soly. of viscose rayon in cold NaOH solns. Exptl. data show the optimum conditions for this analysis. The fabric or yarn cut into pieces about 0.2 cm. in length and weighing approx. 0.2 g. is placed in large test tubes. Into each of a no. of test tubes 50 cc. of 2 *N* NaOH is measured. All the tubes are cooled to −3°. After 0.5 hr. the cold alkali is poured into the tubes contg. the fibers and maintained at −3° for 1 hr.; the tubes are shaken every 10 min. The mixt. is then filtered through a glass filtering crucible with suction, and rapidly rinsed with 25 cc. of 2 *N* NaOH (at −3°) followed by 50 cc. of distd. water. The residue is further rinsed with 200 cc. of 0.2 *N* HCl. The rate of filtering is slowed down by reducing the suction, to allow the acid to be in contact with the fibers for 15 min. The residue is then washed free from chlorides and dried to const. wt. at 105°. Cotton, considerably degraded by chem. attack, becomes more sol. in cold NaOH solns. Several curves and tables are included and their accuracy is indicated as within 1% of the wt. of any of the constituents of the mixt. W. H. Boynton

Processing filament rayon yarns. W. Tabor Robinson. *Textile Bull.* **57**, No. 5, 16–17, 38(1939); cf. *C. A.* **33**, 9655². Leopold Scheflan

The collaboration of the machine industry in the growth and development of the industry of the manufacture of staple rayon. E. A. Anke. *Zellwolle, Kunstseide, Seide* **44**, 383–4(1939).—A survey of old and new industrial processes and installations. A schematic drawing is shown for the continuous mercerization of cellulose on a com. scale. Leopold Scheflan

A testing device for the determination of the water absorption of loose staple rayon. H. Bundesmann. *Deut. Wollen-Gewerbe* **71**, 1208–10(1939); cf. *C. A.* **33**, 4042⁷.— An illustrated discussion. Leopold Scheflan

Printed fabrics from staple rayon. R. Hunlich. *Monatschr. Textil-Ind.* **54**, 208–9(1939).—A brief discussion. Varicolored samples of four fabrics are shown. L. S.

How should rayon wastes be bleached? K. Liebsch. *Monatschr. Textil-Ind.* **54**, 249–50(1939).—The wastes are first pretreated with Na perborate and Na silicate at 60–70° and then bleached with Ca hypochlorite. The procedure is described in detail. Leopold Scheflan

Water in the production of cotton goods. A. V. Boguslavskiĭ. *Khloprhato-Bumazhnaya Prom*, **1938**, No. 10, 41–5; *Khim. Referat. Zhur.* **2**, No. 4, 109(1939).—The requirements of water used in the various operations of the manuf. of cotton goods are given: its transparency, freedom from sediments and from Fe salts, and permissible limit of suspended substances, hardness, and carbonaceous and nitrogenous substances. The amts. of water required in bleaching, mercerization, dyeing, boiling and filling are given. W. R. Henn

Defects in the sizing of cotton warps and their elimination. Th. Schinkl. *Spinner u. Weber* **57**, No. 43, 41–2 (1939).—Breaking of the threads because of low moisture contents is avoided by the use of synthetic fats; excessively high concn. of the size with subsequent undesirable aftereffects is counterbalanced by the addn. of "Aktivin" and Na perborate. Various other defects are discussed with suitable remedies. Leopold Scheflan

Products of decomposition of hyposulfite and rongalite under conditions of their use in cotton mills. B. V. Ponomarenko and Yu. I. Mirtova. *Khlopchato-Bumazhnaya Prom.* **1939**, No. 1, 37–9.—Decompn. of hyposulfite is accompanied by the evolution of SO_2 and starts at ordinary temp. and increases with rising temp. Rongalite is more stable at ordinary temp. and shows its reducing properties at 70°, giving off volatile products. Upon acidification it gives off H_2S and HCHO, while in alk. soln. it is more stable and decomps. only at high temps. B. Z. K.

Textile agents. C. J. T. Cronshaw. *J. Roy. Soc. Arts* **88**, 135–52(1939).—A review. E. H.

Leveling chemicals and procedures. G. Nitschke. *Deut. Textilwirt.* **6**, No. 17, 11–12, 14(1939).—A discussion of latest developments. 6 references. L. S.

Steaming and crabbing. G. L. Atkinson. *Can. Textile J.* **56**, No. 22, 36–7(1939).—A discussion of selecting goods for special treatment, varying widths and reactions to temp., preventing the "cockling" of piece goods, and faults due to excessive tension. Leopold Scheflan

Practical hints on the manufacture of crepe fabrics. M. Gerards. *Deut. Wollen-Gewerbe* **71**, 1264–5(1939).—Various suggestions on dyeing are given. L. S.

The utilization of Tiolan spun goods for woven textile products. R. Hünlich. *Deut. Textilwirt.* **6**, No. 18, 8, 12(1939); cf. *C. A.* **34**, 1180¹.—A description of chem. and phys. treatments. Various recipes are given in detail. Leopold Scheflan

A new process for increasing the wearability of fabrics. A. Hilbring. *Klepzig's Textil-Z.* **42**, 719–20(1939).—Fabrics which are brittle and lack fats are treated by machine with fats, oil or glycerol. The machine can be regulated so that 100 kg. of the fabric is treated with 200–2000 g. of glycerol, fat or oil. The feel of the goods is improved simultaneously. Leopold Scheflan

Is there any generally applicable assistant for the refining of textiles? W. Pflumm. *Deut. Wollen-Gewerbe* **71**, 1210–12(1939).—A discussion of the uses of the textile assistant Modinal in cleaning and dyeing operations. Leopold Scheflan

Normal finishing or superrefining for fabrics for work clothing. Karl Walter. *Deut. Wollen-Gewerbe* **71**, 1201–5 (1939).—A discussion of pretreatments, dyeing, shrinking, washproofing and finishing. Six samples of dyed fabrics are shown in different stages of finishing. L. S.

Practical hints on the finishing of better fabrics for men's coats. Herberger. *Deut. Wollen-Gewerbe* **71**, 1472–4(1939).—A discussion of chem. and mech. treatments. Leopold Scheflan

Estimation of the quality and wearability of worsted yarn fabrics. M. Dubrau. *Deut. Wollen-Gewerbe* **71**, 1166, 1168, 1170, 1172, 1174–6, 1178, 1180, 1182–4(1939). —An illustrated discussion of methods of measurement. Leopold Scheflan

Surface-active agents; their applications in the wet-processing of textiles. Andrew J. Kelly. *Cotton* (Atlanta) **103**, 51–3, 57(Nov., 1939).—An explanation of the properties of the surface-active agents. Methods of evaluation are outlined. Sulfonated oils or low-titer soaps are the principal bases with pine oil, tetralin, trichloroethylene, ethylene dichloride, certain alcs. and cresols as the more common solvents. *Ibid.* 61–3, 108(Dec., 1939).—"Synthetic surface-active agents" are here referred to as those products which are not simple alkali salts or fatty acids or sulfated fatty acids. Included in this are alkyl naphthalenesulfonic acids, sulfated fatty alcs., sulfated esters of polybasic acids, fatty acid condensation products, sulfated aromatic hydrocarbons, sulfated aliphatic hydrocarbons, quaternary aliphatic hydrocarbons, sulfonium and phosphonium groups, mineral oil sulfonates and combinations and variations. The requirements of a wet processing aid, the textile applications, the need for simpler tests for detergency, etc., are discussed. *Ibid.* **104**, 53–5(Jan., 1940).—Wet-processing for Sanforizing and the newer cation-active finishing agents are discussed. Sanforizing or pre-shrinking requires, along with good

penetration, the ability of the material to be easily re-wet after drying. It must be highly absorbent so that shrinking can be expected rapidly, uniformly and completely. Cationic compds. are strongly adsorbed by textile fibers; they also increase the fastness of certain dyes. Characteristics of "natural" and synthetic agents are listed.
W. H. Boynton

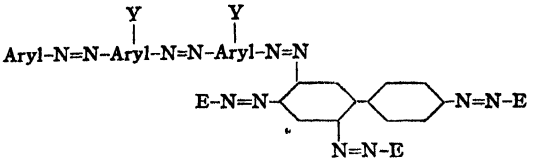
Spots occurring after boiling or alkaline treatments. Asu Vendor. *Monatschr. Textil-Ind.* **54**, 248–9(1939).— Such brown, greasy spots are caused by the pptn. of waxy, fatty, pectin, Fe or Cl ammino compds. as well as ordinary dust following the refinement of cotton. They can be removed by treatment with cold 2–4 °Bé. H_2SO_4. L. S.

Theory and practice of the drying of textiles. Martin Berg. *Spinner u. Weber* **57**, No. 41, 6–8; No. 42, 4, 6; No. 43, 42–6, 48(1939).—Descriptive. L. S.

The filtration of air. Otto Th. Koritnig. *Zellwolle u. Deut. Kunstseiden-Ztg.* **5**, 277–9(1939).— Air-conditioning treatments and devices for textile plants are described.
Leopold Scheflan

The supervision of air humidity and temperature in textile plants. Werner Wilk. *Deut. Wollen-Gewerbe* **71**, 1212–14(1939).—An illustrated discussion of various devices. Leopold Scheflan

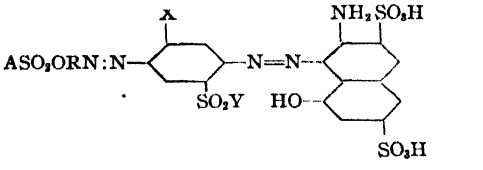
Preservatives in the textile industry. Fritz Ohl. *Monatsh. Seide Kunstseide Zellwolle* **44**, 231–4(1939).— A discussion of the application and detn. of the efficiency of chlorothymol, chlorocresol and phenol salts, salts of *N*-chlorotoluenesulfonamide, halogenated alkyl phenols, chloroxylenol, hexylresorcinol, Me *p*-hydroxybenzoate, etc.
Leopold Scheflan



Textile mildews, their prevention and control. Eric Hardy. *Can. Textile J.* **56**, No. 23, 34(1939).—The occurrence of mildew in yarn or cloth is encouraged by farinaceous sizes, excessive alk. treatment, strong chlorination and nitrogenous decompn. of wool under harsh treatment. Cellulose provides nutrient for certain fungi, while silk gum and raw cotton contain enough albumin for others. An *Aspergillus* mold can grow in an acid condition after wool has been dyed. Phenols and dibromophenol destroy molds but their odors are irritating. Formalin is good except on gelatin sizes. Borax and salicylic acid are useful on all sizes. Hygroscopic $ZnCl_2$ maintains the elasticity of the fiber, but unless it is washed out from the cloth before singeing there may be some tendering of the fabric. Na_2SiF_6 in amts. of 1 part per 400 parts of fabric by wt. provides complete immunization. The nontoxic higher tertiary-alkyl phenol and salicylanilides are improved agents for this purpose. Leopold Scheflan

Scouring action of soap and modern sulfonated textile auxiliaries (Davidsohn, Davidsohn) **13**. Methods of conditioning of water in staple-rayon industry (Castner) **14**. Significance and production of suitable water for use in textile industry (Kehren) **14**. Supervision of water supply [in textile industry] (Boye) **14**. Stereoisomerism of org. dyes and its relation to constitution and properties of reversible polymeric dyes (Scheibe) **10**. Alkyl hydroxy aromatic compds. [intermediates for azo dyes] (U. S. pat. 2,178,571) **13**. Fireproofing cellulose materials [cotton fabrics] (U. S. pat. 2,178,625) **20**. Photographic emulsions on textiles (Dutch pat. 46,703) **5**.

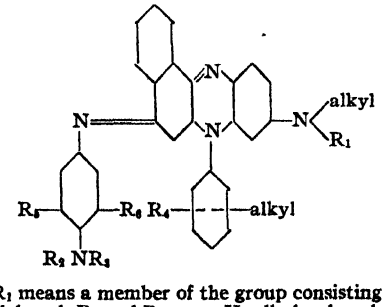
Azo dyes. Fritz Straub and Willi Widmer (to Soc. pour l'ind. chim. à Bâle). U. S. 2,178,054, Oct. 31. From components such as 4-nitro-2-amino-1-phenol-6-sulfonic acid and 5,8-dichloro-1-hydroxynaphthalene and the like, dyes are obtained which dye blue and olive shades when after-chromed and which have the general formula



HOC:Cy.Cy:Cx.CH:CN:NROH in which *x* stands for Me or NO_2, one *y* stands for a sulfonic acid group and the other *y* stands for hydrogen, and R stands for a naphthalene radical which carries the OH group in 1-position and the azo group in 2-position and wherein two H atoms are replaced by halogen.

Azo dyes. Henry Jordan and Swanie S. Rossander (to E. I. du Pont de Nemours & Co.). U. S. 2,178,757, Nov. 7. Dyes which dye cotton fast brown shades have the general formula

in which Y is one or more of the group consisting of H, halogen, alkyl, alkoxy, carboxy, and sulfonic acid, the end Aryl has a single nucleus from the class consisting of benzene, naphthalene, biphenyl, and phenylalkylpyrazolone, the middle components have each a single nucleus from the class consisting of benzene, naphthalene, biphenyl and E is an azo dye coupling component having a single nucleus from the class consisting of benzene, naphthalene, biphenyl, phenylalkylpyrazolone and acetoacetanilide and the compd. has at least one water-solubilizing group.



Disazo dyes. Adolf Krebser (to J. R. Geigy A.G.) U. S. 2,179,190, Nov. 7. From components such as *p*-phenylenediamine-*o*-sulfonic acid-azo-2,8-aminonaphthol-3,6-disulfonic acid and *m*-cresol and the like, disazo dyes are produced of the general formula

wherein A represents an aromatic radical of the benzene series, R represents the radical of a phenol coupled in the *p*-position, X represents one member of the group consisting of H, MeO, EtO and Me, and Y is one member of the group consisting of the OH group, the amido, alkylamido and phenylamido group, an alkyl, the benzyl and an aryl radical of the benzene series, said dyes being dark powders, sol. in water with violet to reddish blue color, dyeing animal fibers in an acid bath violet to reddish blue shades of good fastness to light and fulling. Cf. *C. A.* **34**, 1189[8].

Anthraquinone acid wool dyes. David X. Klein (to E. I. du Pont de Nemours & Co.). U. S. 2,179,217, Nov. 7. Dyes giving level blue to greenish blue shades are prepd. from the 1-amino-4-bromo-5- or -6-hydroxy-contg. aliphatic ethers of 2-anthraquinonesulfonic acid by condensation with arylamines such as aniline, *p*-aminoacetanilide, and the like. Several examples with details are given. Cf. *C. A.* **34**, 1193[4].

Dyes of the naphthophenosafranine series. Eugen Huber (to General Aniline Works). U. S. 2,178,793, Nov. 7. Products which dye clear blue shades are produced by sulfonating a dye of the general formula

where R_1 means a member of the group consisting of alkyl and cyclohexyl, R_2 and R_3 mean H, alkyl or hexyl, and R_4, R_5 and R_6 mean H, alkyl, alkoxy or halogen, until a test portion is sol. in aq. NaOAc soln. Cf. *C. A.* **33**, 1511[5].

Dyeing. Casimir J. Munter (to Hall Laboratories, Inc.). Can. 384,996, Nov. 7, 1939. Textiles are treated in a dyeing bath contg. an alkali metal tripolyphosphate.

Dyeing woolen materials with acid dyes. Colver P. Dyer (to Monsanto Chemical Co.). U. S. 2,179,371, Nov. 7. A method of promoting uniform dye impregnation of woolen textile material with the acid dyes involves using in the dyeing bath a condensation product of naphthalenesulfonic acid and CH_2O which is semigelatinous when mixed with 8.4 parts of water per unit wt. of naphthalene in the condensation product and which serves to retard the fixation of the acid dye to the textile material.

Dyeing mixed textile materials. Geo. H. Ellis and Charles F. Topham (to Celanese Corp. of America). U. S. 2,178,744, Nov. 7. A process for the coloration, with azo dyes, of mixed textile materials contg. filaments, yarns or the like of org. derivs. of cellulose such as cellulose acetate and cellulose filaments, yarns or the like such as those of a woven fabric involves impregnating the materials with the diazotizable base component and the coupling component of the dye for the org. deriv. of cellulose and with the diazotizable base component of the dye for the cellulose material, and then effecting diazotization of the diazotizable bases and coupling of the coupling component for the cellulose deriv. dye, and then coupling with a coupling component of the dye for the cellulose constituents.

Warp dyeing beam. Hubert M. Craig. U. S. 2,177,096, Oct. 24. Various structural details.

Apparatus for conditioning fibrous materials, as in treating cotton with atomized oil. Geo. Hill, Arthur G. Hill, Pearce H. Baker, Leon C. Mitchum and Edward A. Harper (to The Texas Co.). U. S. 2,178,539, Nov. 7. Various structural and operative details.

Treatment of artificial filaments, etc. Henry Dreyfus and Robert W. Moncrieff (to Celanese Corp. of America). U. S. 2,178,743, Nov. 7. App. is described, and a process of improving the tenacity, etc., of artificial filaments, foils, films, etc., of materials such as cellulose acetate which comprises stretching them during their travel from one point to another and while they are in actual contact with a liquid medium, such as water or an alc. or acetone soln., which is at a temp. above its b. p. at atm. pressure and is maintained in a closed vessel under a pressure greater than its vapor pressure at the temp. employed by means of a gas such as air.

Apparatus for handling rayon threads or the like, as in drying. Hayden B. Kline and Alden H. Burkholder (to Industrial Rayon Corp.). U. S. 2,178,104, Oct. 31. Various structural, mech. and operative details.

Insolubilizing organic cellulose derivatives. Walter Frey and Heinz Schwalenstöcker (to E. I. du Pont de Nemours & Co.). U. S. 2,170,017, Aug. 22. Threads, films, textiles or pressed masses comprising a sol. cellulose deriv. such as cellulose acetate or benzyl cellulose are treated with an acid halide of an org. acid which is at least dibasic, such as oxalyl chloride or succinyl chloride until the cellulose deriv. is rendered substantially insol. (suitably in CCl_4 or C_6H_6).

Processing of textile material. Charles N. Frey and Stephen Jozsa (to Standard Brands Inc.). Can. 384,728, Oct. 17, 1939. To desize and increase the wettability, textile materials are immersed in a heated bath contg. a diastatic enzyme and a 0.005–0.04% lecithin with a Lintner value of about 3° is prepd., withdrawn and kept hot until the contained starch has digested, and then rinsed and dried.

Treatment of cellulosic textiles. Joseph H. Shipp (to E. I. du Pont de Nemours & Co.). Can. 385,215, Nov. 21, 1939. Cellulosic fabric is immersed at 20° for 30 sec. in a soln. of 20 g. urea in 100 g. of 96% H_2SO_4, removed from the soln., washed with water and then with 3% NH_3 soln., and dried by ironing.

Treatment of rayon. George M. Allen, Herny J. McDermott and John W. Pedlow (to American Viscose Corp.). Can. 384,401, Oct. 3, 1939. Operative and structural details are described of an app. for the liquid treatment of rayon in coil form.

Knit goods of viscose rayon. Manfred Keller (to E. I. du Pont de Nemours & Co.). U. S. 2,178,759, Nov. 7. Circular knit goods such as underwear are formed of high tenacity rayon thread produced from viscose, having a denier of less than 65, a percentage elongation not in excess of 15, and a wet tenacity of at least 1.5 g. per denier, the thread comprising a plurality of fine filaments twisted together with about 6 turns per in.

Impregnation of silk, viscose rayon and cotton. Gyula Garai. Hung. 122,058, Nov. 15, 1939. Threads or fabrics are dried, treated with soaps of Fe, Al, Sb, Sn, etc., resins (e. g., copal) and other aromatic substances, or artificial resins. If artificial resins are used, the goods are aftertreated with CH_2O.

Fabric with an embossed pattern. Ernst Weiss (to Heberlein Patent Corp.). Can. 384,583, Oct. 10, 1939. A reserve is applied to selected areas of a cotton fabric to form a permanent part which will resist strong solns. of NaOH and repeated washings, and the fabric is treated with a soln. of NaOH (28–38°Bé.) under conditions to produce a strong shrinking action on the cotton fiber between the areas.

The bleaching and permanent azuring of tow, or long threads of flax or cotton. I. R. Maes. Belg. 432,640, March 31, 1939. The fibers are held in a stationary position in a vat, and there are forced through it successively: (1) a soln. contg. an oxidizing bleaching agent and a sulfuric ester of a dyestuff in order to obtain simultaneous bleaching and azuring; (2) slightly acidified water; (3) a soln. of Na acetate or carbonate and a reducing agent.

26—PAINTS, VARNISHES AND LACQUERS

A. H. SABIN AND CARLTON H. ROSE

Technique of the painting process in the rock-cut temples at Badami. S. Paramasivan. *Proc. Indian Acad. Sci.* **10A**, 145–9(1939).—The paintings on stucco in Cave IV (about 6th or 7th century) are in tempera on a carrier of hard, compact, nonporous sandstone, and show no efflorescence. The ground is a rough plaster 0.4 mm. to 0.6 mm. thick, consisting of fine grains 14 μ to 70 μ in diam., mostly of SiO_2 and Al_2O_3. The fine particles made the use of a fine plaster on top of the rough plaster unnecessary. The plaster was of clay contg. Fe and Ca in small amts. The binder was glue. Pigments identified were yellow ocher, red ocher, C, lime and terre verte.
Wm. E. Trout, Jr.

Chalking of titanium dioxide pigmented exterior finishes. D. H. Dawson and R. D. Nutting. *Ind. Eng. Chem.* **32**, 112–16(1940).—D. and N. report, after a study of the chalking of special TiO_2 pigments (*C. A.* **33**, 4136) in enamel vehicle systems, mainly of the alkyd type, that accelerated cabinet exposures show excellent correlation with Florida and Delaware exposures in rapidly chalking enamel films but poorer correlation in more chalk-resistant films and definitely misleading results with respect to films failing by checking. They emphasize the need for including control panels in every weathering series and the necessity for reporting chalking rates in relative rather than absolute terms, as well as the importance of reporting the time of the year at which normal weathering exposures are started. 2 references.

Toward a better understanding of dry colors. H. B. Kirkpatrick. *Am. Ink Maker* **17**, No. 9, 47–9, 53(1939). L. Wilson Greene 1

The dry color "big three." Thomas P. Brown. *Am. Ink Maker* **17**, No. 12, 23, 25–6, 43(1939).—B. suggests a new nomenclature for the different classes of Cr yellows, Fe blues and Cr greens based on their printing tones and tints or their depth of color. He advocates a reduction in the no. of color standards. The general processes for the manuf. of these synthetic colors are described, as well as their chem. compn. Henri Marc 2

The measurement of ink consistency. Robert F. Reed. *Am. Ink Maker* **17**, No. 12, 27, 29, 31, 33(1939).—R. describes the "Inkometer," an instrument of the dynamometer type with which the characteristics of the ink film are measured at printing speeds. Thickness of the ink film and its temp. are controlled and readings are taken in units of torque at 3 accurately controlled speeds. Henri Marc 3

The development of the chemistry and technology of driers in recent years. A review of the literature from 1933. Felix Wilborn. *Farben-Ztg.* **44**, 1050–1, 1067–8, 1082–3, 1099–1100(1939).—Over 90 references. J. W. Perry

Preparing stable naphthenate driers. A. Drinberg and A. Parfenova. *Maslobol'no Zhirovoe Delo* **15**, No. 3, 29–32 (1939).—Naphthenate driers, prepd. in the form of acid salts from naphthenic acids refined by distn. with superheated steam, are preferable to the neutral salts because of better soly. and stability. They are readily oil-sol., leaving no insol. residue if gently warmed. As a drier Co naphthenate is superior to the linoleate; it is also paler in color and has lower viscosity. For prepn. of the driers the 2-stage method is recommended for Mn, Co and Ca naphthenates, and the fusion method (120–125°) for Pb naphthenate. Linseed-oil paint films show about the same O absorption and hardness with naphthenate as with linoleate driers. Tabulated data and curves show the ash content and metal content of acid and neutral naphthenates of Mn, Co and Pb; max., optimum and min. drier concn. in paints (same naphthenates); and the rate of drying of paint films, in comparison with Co linoleate as drier. Julian F. Smith 4

Slow increase in tung oil production. W. E. MacKee. *Am. Paint J.* **24**, 14, 16, 18, 20 (Jan. 8, 1940); cf. *C. A.* **34**, 8978. W. H. Boynton 5

The catalysis of stand-oil formation by soluble heavy-metal compounds. Felix Wilborn. *Farben-Ztg.* **44**, 1011 (1939).—Various heavy metal resinates were effective in increasing the extent of viscosity rise observed with linseed oil when heated to 300° for 16 hrs. and then cooled to room temp. The order of decreasing effectiveness of the resinates at 2% concn. was: Th, Pb, Ni, Co, Fe, Ca, Mn, Ce, Cr and U. If the viscosity of the heat-treated oil was measured at 60°, then (*a*) the Pb resinate (I) appeared much more effective than the virtually ineffective Th resinate (II) and (*b*) I was increasingly effective on increasing its concn. from 0.5% to 4%, while II was virtually ineffective at concns. less than 8%. J. W. Perry 6

Some studies in the drying of raw soybean oil films. L. L. Carrick and A. A. Jigger. *Am. Paint J.* **24**, 7–9, 18–19(Jan. 1, 1940).—A study of the effect of drying upon the I no., sapon. no., acid no., thiocyanate no., acetone-insol., Ac no., peroxide no., wt. and combustion analysis of the films. The relation of the age of soybean oil films to the change in wt., to the percentage of O, to percentage of acetone-insol., and peroxide no. are shown in curves and combustion data are given for soybean-oil films from the day of application to 100 days of aging. *Ibid.* 43–6(Jan. 1, 1940).—Data show that between the 10th and the 15th day of drying there is a 100% increase in acetone-insol., between the 15th and 40th day a steady increase, and between the 40th and 100th day it remains const. No definite conclusion can be drawn from the data already collected until the analyses of the volatile products evolved during drying of these films at various stages of drying have been finished. Thirteen references. W. H. Boynton 7 8 9

Tungstate and molybdate toners. Production of phosphotungstic acid, phosphomolybdic acid and mixed complex acid toners by precipitation of basic dyes. Arthur Linz and L. W. Coffer. *Am. Ink Maker* **17**, No. 9, 39–42, 55, 57, 59, 61, 63, 65, 67; No. 10, 29, 31, 33, 35; No. 11, 27, 29, 31, 33, 45(1939); cf. *C. A.* **32**, 5045[3].—Seven toners from each of 10 different dyes were prepd. and tested under as nearly identical conditions as possible, with phosphotungstic (I), phosphomolybdic (II) and phosphotungsto-molybdic acids (III). The latter was employed in the following ratios: 90W-10Mo, 75W-25Mo, 50W-50Mo, 25W-75Mo, and 10W-90Mo. A stock soln. of the dye was prepd. and divided into several equal portions. Each portion was pptd. with a different complex acid. Stock solns. of I and II were adjusted to the same mol. concn. Stock solns. of III were used in the mol. ratios given above. The calcns. upon which the soln. concns. were based, and analytical data for resulting toners, are given in detail. The following properties of the toners were detd.: sp. gr., oil absorption, ease of grinding, rub-out, transparency, tinting strength, resistance to baking, resistance to light (full strength and tints), and bleeding tests (with litho varnish, linseed oil, rosin oil, mineral oil, petrolatum, butyric acid, oleic acid, CH_3COOH, H_2SO_4, soda ash, NaOH, soap, H_2O, denatured alc., lacquer solvent, C_6H_6, mineral spirits, turpentine and hot paraffin). The following dyes were used: Thioflavine TG, Auramine O, Rhodamine 6G, Rhodamine B, methyl violet, malachite green, Brilliant Green, Brilliant Blue 6G (Peacock Blue), methylene blue and Victoria Blue BO. The data on the pptn. of the 70 toners and the properties of each are presented in 20 tables. The research is discussed under the headings: color of the complex acids, complex acid required and cost, filtering of pptd. colors, maintaining pH during pptn., yield, percentage of ash left after ignition of toner, ratio of dye to complex, color and brilliancy, sp. gr., oil absorption, vol. of ink, tinting strength and light fastness. L. Wilson Greene 10

Litho varnishes. Joseph Mattiello. *Am. Ink Maker* **17**, No. 11, 23, 47(1939). L. Wilson Greene 11

How should "synthetic varnishes" be applied? Heinrich Wulf. *Farben-Ztg.* **44**, 1136–7(1939).—Important points in applying alkyd resin varnishes are (1) rapid application as a thin film, (2) proper surface prepn. and (3) use of the right type of thinner depending on conditions. J. W. Perry 12

Making a lacquer for tin cans. N. Rubinskii. *Maslobol'no Zhirovoe Delo* **15**, No. 2, 42(1939).—A satisfactory lacquer for *food* tins was obtained by blending 1 part Albertol resin with 1 part oxidized linseed oil in 2 to 2.2 parts turpentine. Viscosity of the oil (pipet viscometer) was 480–600 sec., and of the lacquer 100–105 sec. (raw linseed oil, 7 sec. in the same viscometer). Two coats on tinplate, baked 25 min. at 180°, gave a finish which was hard to the fingernail test and withstood stamping and other operations to which the tinplate was subjected. The lacquer was transparent, clear and practically free from heavy metals (Pb 0.0027, Cu 0.0032%). A Co drier was used. A test of its utility for food tins showed that the finish retained satisfactory hardness after boiling 2 hrs. in aq. solns. of HOAc (5%), NaCl (3%), tartaric acid (2%) and sugar (60%). Julian F. Smith 13

Nitrocellulose baking lacquers. II. A. Kraus. *Farben-Ztg.* **44**, 1150–1, 1166–7(1939); cf. *C. A.* **32**, 1496[8].—Formulation problems are discussed. The character of the alkyd resin used influences greatly the mech. properties of the final film, with alkyds having a low oil content producing the more brittle, less elastic films. Low viscosity varieties of nitrocellulose are recommended for use in the ratio of 1 part to 4–6 parts of alkyd resin. The baking period at any given temp., e. g., 120°, can be shortened (1) by selecting an alkyd resin having more pronounced drying properties, (2) by using metallic driers and (3) by formulating with limited amts. of non-drying resins, e. g., certain phthalate resins. Gloss can be improved by relatively small amts. of higher-boiling solvents or of plasticizers having solvent power for nitrocellulose. Weathering expts. in progress show that properly formulated films withstand exposure for 2 yrs. without signs of failure. J. W. Perry 14

Developments in lacquers and enamels for industrial finishing during 1939. G. Klinkenstein. *Products Finishing* 4, No. 4, 34–6(1940). Leopold Scheflan

Acid-hardening artificial resin lacquers. A. Greth. *Angew. Chem.* 52, 663–6(1939).—A summary. K. K.

Continual observation of changes in weight at oven temps. [drying and oxidation of oils] (Beckel, Sharp) 1. C blacks andlamp blacks [for use in paints and lacquers] (U. S. pat. 2,178,382) 18. Pitch compns. for use as a paint (U. S. pat. 2,178,770) 20. Compds. of the perylene series, for coloring lacquers (U. S. pat. 2,178,521) 22. Luminous and radioactive compns. for luminous paints (U. S. pat. 2,178,961) 3.

Alkyd resin paints. Friedrich Frick (to I. G. Farbenind. A.-G.). U. S. 2,178,474, Oct. 31. A color pigment is used with an aq. emulsion of a synthetic resin such as may be formed from a polyhydric alc., a polybasic acid, an unsatd. fatty acid of the drying type, and an emulsifying agent such as the NH_4 salt of diisopropylnaphthalene sulfonic acid. U. S. 2,178,475 relates to coating compns. suitable for use on wood, felt, artificial stone, etc., which contain a filler such as Fe_2O_3, ground slate and talcum together with an emulsion of generally similar character. An aq. ammoniacal soln. of casein may be used with the various other specified ingredients.

Composition for water paints. E. Goffart. Belg. 432,762, March 31, 1939. The basis of the material is a double Ca Al silicate contg. excess lime, mixed dry with colored pigments, a certain proportion of casein or Ca caseinate, and a small quantity of K Al sulfate or $Al_2(SO_4)_3$.

Metal-paste pigments. Edwin L. McMahan (to Aluminum Co. of America). U. S. 2,178,179, Oct. 31. A stabilized metal-paste pigment having good persistence of leafing power comprises flakes of metal such as Al, together with a leafing agent such as stearic acid, and a small proportion (suitably about 0.1% or less) of phenol, monobenzyl amino phenol, *p-tert*-amyl phenol, or guaiaphene. U. S. 2,178,180 involves the use together of metal flakes, a leafing agent, and α- or β-naphthol. U. S. 2,178,181 involves the use together of metal flakes, a leafing agent, and α- or β-naphthylamine, amylamine, diamylamine or triamylamine.

Titanium-containing lithopone. A. M. Brusilovskiĭ, S. F. Lukovskiĭ, V. V. Andreev, F. S. Sigal and B. E. Boguslavskiĭ. Russ. 51,751, Sept. 30, 1937. A soln. of $Ti(SO_4)_2$ is treated with a Zn-contg. material, e. g., $ZnCO_3$, boiled, the pptd. titanic acid filtered off, the filtrate again treated with Zn-contg. material, and freed from Fe and other salts of heavy metals in the usual way, the purified $ZnSO_4$ soln. mixed with the previously sepd. titanic acid, the mixt. treated with BaS, and the pptd. pigment sepd. and heated to incandescence.

Water-dispersing zinc sulfide pigment. James E. Booge (to E. I. du Pont de Nemours & Co.). U. S. 2,178,334, Oct. 31. A process for the production of a ZnS pigment having a water absorption less than 40 involves adding to a dry calcined ZnS-contg. pigment about 0.18–0.36% of Na pyrophosphate and uniformly mixing.

Pigment for nitrocellulose lacquers. Adolf Detre. Hung. 121,983, Nov. 2, 1939. The pigment is ground with a heavy-metal soap. The chief component of the base material is salep roots or similar mucilaginous substance made up with water to a sirup, treated with 4 times as much of a sirup of vegetable gums contg. little arabin and much cerasin and assorin. A neutral, acid- and alkali-resistant filler (e. g., powd. steatite, serpentine, or Al silicate) is added to give the desired plasticity. In lacquers to be applied on metal surfaces, 1–2% mineral acid is added. This base material has less tendency to crack off than have those contg. lime and chalk.

Drying oil. Izador J. Novak (to Raybestos-Manhattan, Inc.). U. S. 2,178,604, Nov. 7. A blown drying oil of the nonconjugated type having a conjugated system, insol. in EtOH, sol. in petroleum solvents, liquid at 25°, and suitable for use with a synthetic resin on clutch facings, etc., is produced by blowing an oil such as soybean, linseed or hemp seed oil at 25–70°, with an O-contg. gas.

Preparing mineral oils for use in paints. Allan B. Ruddle. U. S. 2,178,705, Nov. 7. The oil is mixed and heated with a soln. of an alkali metal silicate and an alkali metal fluosilicate, and an alum is then added.

Bronze powder-containing coating compositions. Joseph F. Hofmann (to Acme White Lead & Color Works). U. S. 2,178,018, Oct. 31. A nonleafing coating compn. is prepd. by grinding bronze powder in a highly volatile solvent such as a hydrogenated naphtha of low b. p. until the powder is reduced to a state of extreme fineness, then mixing it with a synthetic resin varnish to form a uniform dispersion of the powder in the varnish and solvent.

Printing on pellicles of hydrophilic colloid. Ralph T. K. Cornwell (to Sylvania Industrial Corp.). Can. 384,909, Oct. 31, 1939. A pellicle of hydrophilic colloid, e. g., cellulose hydrate, is impregnated with an org. water-miscible dye solvent that is a swelling agent for the colloid, and printed in the gel state with an ink contg. a substantive sol. in the solvent. An app. is described.

Rosin size. Benjamin H. Thurman (to Refining, Inc.). U. S. 2,178,532, Oct. 31. An arrangement of app. is described, and a process of producing rosin size and continuously recovering turpentine from resinous material (such as a pine gum) which liberates turpentine when heated, the process involves: continuously flowing into a reaction zone closed from the atm. a stream comprising proportioned quantities of the resinous material and an aq. alk. soln. such as one of Na_2CO_3, heating the material in the reaction zone to form turpentine vapor and rosin size in the reaction products; continuously moving the reaction products into a sepg. zone; continuously withdrawing the turpentine vapor from the sepg. zone; condensing the turpentine vapor; and removing the rosin size from the sepg. zone. Various similar processes are described.

27—FATS, FATTY OILS, WAXES AND SOAPS

E. SCHERUBEL

Hydrolysis of fats and fat acid esters. I. Saponification velocity of fats and fat acid esters. Toyoki Ono. *J. Agr. Chem. Soc. Japan* 15, 843–56; *Bull. Agr. Chem. Soc. Japan* 15, 131-2(in English)(1939).—The fats and oils were sapond. in the homogeneous medium consisting of C_6H_6 and KOH alc. soln. At lower temp., the fish oil was more easily sapond. than the vegetable oils. The sapon. of the solid fats was more rapid than that of the oily fats at 30°. The reaction velocity at 30° was large at the beginning of the sapon. and then diminished. The reaction was special and irregular. II. *Ibid.* 953–65.—When the amt. of the fat was larger than that of KOH used for the sapon., the reaction velocity diminished. The reaction velocity was also changed with the concn. of KOH. The castor oil and the perilla oil were sapond. by only alc. KOH with larger reaction velocity than the sardine oil, cacao butter and olive oil. It may be due to the soly. of the oils in alc. The reaction velocity of the fat acid esters decreased reciprocally with the mol. wt. Aromatic dicarboxylic acid esters were more easily sapond. than aromatic monocarboxylic acid esters. In the sapon. of glycerides of fat acids, the effect of the mol. wt. was not remarkable.

Y. Kihara

The solid acids of olive oil. René Marcille. *Compt. rend.* 209, 730-2(1939).—Different olive oils, e. g., from Northern Tunis, contain solid acids which sep. out in a variety of cryst. forms when the oils are cooled to 12–14° for 24 hrs. The Pb salts of solid fat acids from noncongealing oils are sol. in Et_2O, the acids show Bellier no. 25.75 (cf. *C. A.* 29, 6449⁴); the Pb salts of solid acids from

congealing oils are only partly sol. in Et_2O, the acids show m. p. 56.5°, Bellier no. 22.33. These differences indicate the presence of other solid acids besides palmitic acid (I). Sepn. of these acids through their K salts, or by differences in soly. in EtOH, could not be effected. By fractional addn. of LiOAc to the alc. soln. of 25 g. of the solid acids from noncongealing oils I (m. p. 59.5°, Bellier no. 18.75) was sepd. from the last 3 fractions as the Li salt. Three repetitions of this fractionation furnished 92 mg. of arachidic acid (II), characterized by its insoly. in EtOH, m. p. 73.5°, Bellier no. 60; 33 g. of solid acids from congealing olive oils rendered 42 mg. of less pure II. Abnormal Bellier nos. are obtained in the analysis of olive oils contg. II if only one-half of the usual vol. of EtOH is used in the fractional pptn. of the solid acids. The Hilditch-Schuster method gave no reliable results, even with very congealing oils; the solid lipides from such oils consist of oleodipalmitin. Alfred Burger

The Bellier number and its use in the detection of peanut oil in olive oil and various other applications. R. Marcille. *Ann. chim. anal. chim. appl.* **21**, 311-21(1939); cf. *C. A.* **29**, 6449⁴.—The test, while not very specific, is valuable for detecting of the adulteration of olive oil with peanut oil. Since the original publication is not easily accessible to many chemists, the present paper represents a complete review of the subject and, besides telling exactly how to carry out the work and interpret results, gives an account of some further expts. Fairly good results were obtained in estg. the quantity of peanut oil present and successful applications were the detection of peanut oil in canned sardines and in olive marc. The Bellier no. can also serve to establish the purity of various fat acids. W. T. H.

Cottonseed industry 1939. S. M. Harmon. *Mfrs. Record* **109**, No. 1, 46, 62(1940).—A survey. L. S.

Identification of commonly used waxes in admixture. Samuel Zweig and Abraham Taub. *Ind. Eng. Chem., Anal. Ed.* **12**, 9-14(1940).—The systematic identification of waxes is based on variation in proportion of acids, alcs. and hydrocarbons, differences in chain length of the two components of the ester, and the presence of addnl. distinctive components such as resin-like substances and ketones. The methods employed are based on the detn. of phys. and chem. consts. such as m. p., sapon. value, acid value, acetyl value and solution temp. Sapon. values below 50 indicate the presence of paraffin or ozocerite; low acid value below 3 or 4 excludes the presence of more than 10% beeswax, montan or candelilla wax and indicates the absence of rosin or stearic acid. Acid values greater than 20 suggest the presence of more than 10% stearic acid, or 13% rosin or montan wax. A m. p. above 75° indicates more than 10% carnauba wax in the mixt., and a high m. p., ozocerite and montan wax. Acetyl values above 21 indicate more than 38% carnauba or 11% cetyl alcohol; below 10, carnauba is absent or is present in less than 15%. For 0.25 g. in 10 cc. BuOH, pptn. temps. above 53° suggest carnauba more than 7-10% or ozocerite more than 5%; above 75° ozocerite more than 20% and below 50° carnauba or ozocerite less than 5%. Information to be obtained from soly. in hexane, EtOH and AmOH is described. The hydrocarbon fraction of the wax mixt. offers a means for detecting the presence of ozocerite or paraffin. The wax hydrocarbons are carbonized when heated to 110° with concd. H_2SO_4 while the paraffin hydrocarbons are not, and can be extd. from the dild. acid mixt. with ether or ligroin. A schematic outline for the identification of the various waxes and allied substances mentioned above and their semiquant. evaluation, graphs for pptn. temp. studies and phys. and chem. properties of fractions sepd. from wax as well as a compilation of the important distinguishing characteristics of each wax, are included. W. A. Cook

The trend of soap progress. H. L. Ramsey. *Soap* **16**, No. 1, 30-1, 69(1940).—Recent progress has been chiefly in the chemistry of fatty materials. The greatest improvement has been in soap powders whose properties have been enhanced by addns. of various chemicals such as phosphates. E. Scherubel

Laboratory boiling of soap in glass. Robert E. Divine. *Oil & Soap* **17**, 2-4(1940).—By using a cone-shaped Pyrex glass vessel of 1700-ml. capacity it is possible to carry out small-scale sapon. satisfactorily. The cone is supported by a flat ring of galvanized iron in a large beaker of boiling water. Steam for agitation is generated in a 1-l. Erlenmeyer flask. A glass tube conducts the steam to the bottom of the cone and the ascending bubbles of steam furnish the mixing required. The flask is also equipped with a short piece of rubber tubing and a screw clamp which serves as an air vent to safeguard against sucking the contents of the cone into the steam generator when heating is stopped. The use of this app. is said to permit plant operations to be duplicated in glass vessels as small as 750-ml. capacity. E. Scherubel

Effect of alkaline electrolytes on the foaming ability of soap solutions. G. L. Yukhnovskiĭ. *Trudy Khar'kov. Khim.-Tekhnol. Inst. S. M. Kirova* **1**, 98-107(1939).—Tabular and graphical results are given on the effect of soda on the foaming ability of various soap solns. The foaming ability of the soap solns. was detd. by titrating the soda with a 0.5% soap soln. until a foam was obtained which remained stable for three min. B. Z. Kamich

Detersive efficiency of tetrasodium pyrophosphate. I. W. W. Cobbs, J. C. Harris and J. R. Eck. *Oil & Soap* **17**, 4-21(1940).—Washing tests were conducted to det. the effect of single builders with soap to obtain data on the specific action of each alkali and the program was extended to include both binary and ternary combinations of alkalies. There are 63 graphs from which it is concluded that tetrasodium pyrophosphate has the ability to increase suds, detergency and also the amt. of builder without diminishing the cleansing efficiency of the soap. It also permits a low pH for use in household soaps. Its value in combination with other builders awaits completion of work on ternary and quaternary combinations. E. S.

Scouring action of soap and modern sulfonated textile auxiliaries (Davidsohn, Davidsohn) **13**. Changes in gossypol during ripening and storage of cottonseed (Podol'skaya) **11D**. Compds. of the perylene series for coloring waxes and fats (U. S. 2,178,521) **22**. Aliphatic polyamines [for emulsifying oils and fats] (U. S. pat. 2,178,522) **13**.

Treatment of fish oils. William Hassard. Can. 384,364, Oct. 3, 1939. Fish oils are treated with an emulsion of aq. $KMnO_4$ and Mg hydrosilicate, and the mixt. centrifuged.

Soap making and glycerol recovery. Benjamin H. Thurman (to Refining, Inc.). U. S. 2,179,001, Nov. 7. An arrangement of app. is described, and a method of making soap by the reaction between a saponifiable material and a saponifying material, which includes the steps of: saponifying a mixt. of the materials under heat while maintaining the temp. below that value at which discoloration owing to traces of unreacted saponifiable material will result, thus producing a soap mixt. contg. soap, glycerol and traces of unreacted saponifiable material; then processing the soap mixt. to saponify the traces of unreacted saponifiable material to produce a completely saponified soap product still contg. glycerol; then heating the soap product to a higher temp. and subjecting same to a vacuum the heating being sufficient to cause vaporation of glycerol under the vacuum conditions; sepg. glycerol vapor from the soap while maintaining the soap in molten, plastic or semiplastic condition while subjected to the vacuum conditions and promptly, substantially as soon as the soap has been deposited in the vacuum, removing the same without impairing the vacuum. Cf. *C. A.* **33**, 3620⁸.

Soap. Benjamin Clayton (to Refining, Inc.). U. S. 2,178,987, Nov. 7. An arrangement of app. is described, and a 2-step process for making soap which involves: continuously mixing in stream flow saponifiable and saponifying materials and effecting substantially complete sapon. while maintaining a temp. below the m. p. of the resultant soap when anhyd., thereafter transferring the resultant mixt. to a sep. and independent high-temp.

treating zone and there imparting a temp. substantially above the m. p. of the soap when anhyd., quickly removing a stream of the mixt. from the high-temp. zone and introducing the same into a vapor sepg. chamber, continuously removing the vaporized materials and removing the molten anhyd. soap from the vapor sepg. chamber. Cf. *C. A.* **33**, 1168[8]. U. S. 2,178,988 relates to app. for making soap by such a process.

28—SUGAR, STARCH AND GUMS

J. K. DALE

Standardization of the methods of sampling products preceding control analyses in sugar industry and refinery. Georges Capelle. *Sucr. belge* **59**, 81–7(1939).
W. W. Binkley

Classification of raw sugar for refining purposes. Walter Godchaux, Jr. *Sugar J.* **2**, No. 4, 14–15(1939).—A classification based on solid impurities, color and filtration no. is recommended. Colin W. Whittaker

Experiments conducted by the American Sugar Refining Co. on the keeping qualities of raw sugar. M. D. Scott. *Sugar J.* **2**, No. 5, 29–30(1939).—It is concluded from storage expts. that a humidity-controlled warehouse is advisable in semitropical climates. C. W. Whittaker

The "Fortier" (sugar) mill clarification process. W. A. Rolston. *Proc. 12th Ann. Conf., Asoc. tecnicos azucar., Cuba* **1938**, 202–10.—This process consists in separately collecting, heating and liming the juice of the 3rd mill and returning it for maceration between the 2nd and 3rd mills. A pos. increase in purity, more colloid elimination and a reduction of vol. of ppt. from the mixed juice are obtained. Application of the alk. maceration fluid reduces the acidity of the mixed juice and diminishes corrosion. O. W. Willcox

Notes on the mechanism of continuous clarification. Diaz Campain. *Proc. 12th Ann. Conf., Asoc. tecnicos azucar., Cuba* **1938**, 91–6.—Multiple-compartment sugar-juice clarifiers with peripheral feed (Diazco type) are compared with clarifiers of the central feed type; the former presents hydraulic conditions in which there is less turbulence. O. W. Willcox

Basic lead acetate, its composition and clarifying qualities. C. R. v. Stieglitz. *Dept. Agr. Brisbane, Queensland, Bur. Sugar Expt. Stas., Tech. Commun.* No. **10**, 173–6(1939).—Twenty-five samples of Horne's dry lead were obtained from different sources and compared. Substantial variations in compn. and moisture content were found. The clarifying efficiency varied chiefly with the state of subdivision of the product, but the polarization sugar values showed little difference. Small variations in Pb content are apparently without much significance, but close attention should be paid to the moisture content. O. W. Willcox

New viewpoints on juice purification. F. Tödt. *Centr. Zuckerind.* **47**, 886–7, 894–5(1939).—After thin juices were boiled 2 min. the CaO content was reduced to 0.0071 and 0.0041% by 0.01 and 0.02% soda; to 0.0037 and 0.0023% CaO by 0.01 and 0.02% KH_2PO_4; boiling 5 min. with 0.02% soda left 0.0029% CaO; 0.02% KH_2PO_4, 0.0012% CaO. Na_2HPO_4 delimed as effectively as KH_2PO_4. Soda treatment introduces 3 times as much alkali on a mol. basis as does treatment with KH_2PO_4. Phosphate deliming impedes color formation caused by invert sugar in the same manner as the sulfurization of beet chips. W. W. Binkley

Gas formation in diffusion batteries. Gottfried Mück. *Deut. Zuckerind.* **64**, 1002(1939).—Two theories prevail on gas formation in diffusion batteries: (1) the action of acidic juices on metal portions of the batteries, (2) the action of microörganisms on carbohydrates in the juices. The gases consisted of 1 part CO_2 and 4 parts H. W. Binkley

Nitrogen content of sugar-cane juices and color of cream jaggery. G. Ganapathi Ayyar and K. Bhushanam. *Madras Agr. J.* **27**, 161–6(1939).—A study was made of the inferior color of cream jaggeries sometimes developing during the later stage of the boiling of carbon-treated juices. No correlation was found between the sucrose or glucose contents and the discoloration, but a close relationship was found between the N content of the juices and the color produced. More than 80% of the N was present in sol. form and more than 50% was present as amino acids. The discoloration was produced experimentally by boiling jaggery with asparagine and it is concluded tentatively that the color production is due to interaction of amino acids and reducing sugars. Numerous detns. of color, glucose, sucrose, N and Brix of raw and filtered juices are reported. Colin W. Whittaker

Studies on beet cultivation and juice production by better-quality factories. T. Wintzell. *Centr. Zuckerind.* **47**, 933–5, 961–3, 977–9, 997–8, 1014–16, 1030–2, 1049–52 (1939).—18 references. W. W. Binkley

Prevention of deterioration of sugar in storage. W. S. Daubert. *Sugar J.* **2**, No. 5, 24–8(1939).—Precautions necessary to avoid deterioration of sugar in storage are reviewed, especially moisture content, particle size, freedom from bagacillo, cleanliness, etc. Colin W. Whittaker

Indeterminate losses in the production of sugar from sugar beets. H. Claassen. *Sucr. belge* **59**, 72–4, 87–92, 108–14(1939).—Indeterminate losses are due to the methods of weighing, sampling and analysis of beets; action of microörganisms during diffusion; action of elevated temps.; defecation and carbonation; passage of difficultly sol. sugar-lime compds.; evapn. and cooking. W. W. Binkley

Fiber content of commercial varieties of Louisiana sugar cane. M. A. McCalip. *Sugar J.* **2**, No. 4, 25–8, 31 (1939).—See *C. A.* **33**, 9700[5]. Colin W. Whittaker

Present state of the high-test molasses industry. Committee Report. *Proc. 12th Ann. Conf., Asoc. tecnicos azucar., Cuba* **1938**, 232–5.—Acid inversion of cane sirups with subsequent neutralization with lime has the disadvantage of much decompn. of sugars and incrustation of evaporators, which are avoided by invertase inversion according to the Guerrero process: juice from the last grinding mill, which is rich in proteins and amino acids, is pasteurized, cooled, treated with $(NH_4)_2SO_4$, phosphate and other yeast nutrients, and seeded with a special strain of yeast (No. 206 CC) which contains approx. 10 times as much invertase as bakers' yeast. After 10–12 hrs. the yeast suspension is centrifuged to 12% of its original vol. and fed continuously to the stream of sirup coming from the evaporators at 55 Brix, a pH of 6.0–6.5 and previously cooled below 60° at the rate of 4 vols. yeast suspension to 100 vols. sirup; 65% inversion is obtained in 10 hrs. or in 5 hrs. with 8 vols. of yeast; 67.67% inversion can be obtained in 30 hrs. with 1.25% yeast. Exts. indicate that by leaving the yeast in the sirup a product balanced in protein and carbohydrate is obtained which can compete with any other cattle feed. O. W. Willcox

Some physical properties of molasses. A. H. Praeger and J. L. Heron. *Dept. Agr. Brisbane, Queensland, Bur. Sugar Expt. Stas., Tech. Commun.* No. **9**, 149–70 (1939).—The Brix of final molasses depends on the compn. of the sample; the result is more accurate with the smaller dilns. No practical relationship is found between refractometric Brix, densimetric Brix and dry substance. For a given reduction in the supersatn. coeff. viscosity is reduced to a greater extent by heating than by diln. Molasses of high Brix values show anomalous viscosities, perhaps because of the formation of complex internal structures. No definite value for surface tension could be obtained, but it is perhaps of the order of 60 dynes/sq. cm. O. W. W.

Manufacture of high-test molasses. M. A. Mascaró. *Proc. 12th Ann. Conf., Asoc. tecnicos azucar., Cuba* **1938**, 199–201.—The concd. cane juice (40–42 Brix) is mixed with dild. acid and heated to 215–20°F. by pumping

through the 1st of 2 high-speed heaters; in the receiving tank the inversion is allowed to proceed until the temp. has fallen to 175°F., when the liquid is again passed through a similar heater to a 2nd tank where the purity is allowed to drop to the desired figure. This system advantageously replaces the ordinary "stationary" heating in a single tank, as there is less caramelization and decompn. O. W. Willcox

Molasses dilution tests. G. H. Jenkins. *Dept. Agr. Brisbane, Queensland, Bur. Sugar Expt. Stas., Tech. Commun.* No. 8, 137-48(1939).—Factory-scale expts. showed that dilg. massecuites with water gives a substantial improvement in the purity of centrifugal sugar, but in the app. used it was not practicable to reduce the supersatn. coeff. lower than 1.09 without appreciable resoln. of cryst. sugar. On the other hand, resoln. can definitely be avoided by heating at the satn. temp. of the molasses; the supersatn. can thus be reduced practically to 1.00 without resoln., with proportionate reduction of viscosity. Where the utmost reduction of viscosity is required diln. is definitely inferior to reheating. O. W. Willcox

Utilization of blackstrap molasses. Wm. L. Owen. *Proc. 12th Ann. Conf., Asoc. tecnicos azucar., Cuba* 1938, 227-31.—An outline of recent trends. O. W. W.

Spontaneous combustion of Egyptian sugar-cane molasses. C. A. Browne. *Ind. Eng. Chem., News Ed.* 17, 734-6(1939).—Summary of a report by H. Naus Bey. Molasses stored in tanks frequently undergoes spontaneous decompn., causing frothing and overflow. In open tanks, exposed to the sun, it may even completely carbonize. The most important factors in bringing about this condition are high concn. (over 42° Bé.) and high temp. in conveying and storing the molasses. Contributing factors of lesser importance are an alk. reaction of the molasses, and the use of SO_2 in the defecation process. The decompn. is not caused by microorganisms, but is due to the formation of highly labile unsatd. org. nonsugars of high C content, by progressive dehydroxylation. Mineral salts act as catalysts in this reaction. Illustrated. F. W. Zerban

Bagasse furnaces. E. W. Kerr. *Trans. Am. Soc. Mech. Engrs.* 61, 685-91(1939).—Bagasse, the woody fiber remaining after removal of the juice from sugar cane, makes up approx. 27.5% of the wt. of the cane (La), contains approx. 50% moisture, and is used as fuel in the generation of steam for the refinery. Practically all types of boilers are used for burning bagasse, water-tube boilers predominating. Types of bagasse furnaces are grate, hearth and combination grate and hearth; boiler and furnace efficiencies average 50%, with best installations averaging 55–60% (66% for a Ward furnace). Cuban bagasse contained H 5.8, C 46.31, O 45.82, N 0.26 and ash 1.81%. The calorific value of bagasse is 8000–8600 B. t. u./lb. on the dry basis. George Ayers

Modernization of the Maine potato starch industry. Charles A. Brautlecht. *Rept. New Engl. Assoc. Chem. Teachers* 41, 59–72(1939).—A survey. L. Scheflan

Use of the Kurnakov recording pyrometer in the study of changes in starch. V. I. Nazarov and A. V. Nikolaev. *Compt rend. acad. sci. U. R. S. S.* 24, 263–5(1939)(in English); cf. *C. A.* 33, 4072[8].– Heating curves for potato-starch suspensions in 1 *N* solns. of NaCl, KCl and KNO_3 show endothermal effects (during gelatinization) at 62.5°, 57.5° and 56°, resp., which are in approx. agreement with the values obtained by the Gorbachev method. When starch suspensions in 1 *N* solns of HCl and HNO_3, resp., are heated, both gelatinization and dextrinization show endothermal effects. Heating curve data for air-dried starch, com. sol. starch, and for starch in formamide are discussed. George Ayers

Behavior of topped beets remaining in the ground (Schneider) **11D.** Use of $CaCN_2$ [for sugar-cane cultivation] (Gordon) **15.** Statistical investigations on sugar-beet yields (Bruinsma) **15.** Importance of biol. research [for water that is used in sugar extn.] (Batta, *et al.*) **14.** Structure of cellulose and other polymers related to simple sugars (Haworth) **10.** Stock feeds [use of carbonation sediment from sugar manuf. and molasses or sirup from beet- or cane-sugar manuf.] (U. S. pat. 2,170,713) **12.**

Decolorizing sugar solutions. Hans O. Kauffmann (to Buffalo Electro-Chemical Co.). U. S. 2,178,587, Nov. 7. An aq. soln. of sugar of high sugar content is treated, at a moderately elevated temp. (suitably about 55–60°), with a hypochlorite and a precipitant agent such as mono-Ca phosphate, and subsequently treated with H_2O_2 in about 5 times the quantity required to dechlorinate the soln. for preventing return of color.

Separating sugar from mother liquor by centrifuging. Walter E. Smith. U. S. 2,179,436, Nov. 7. Centrifuging is effected in a separator sealed against the passage of air currents through it while the temp. of the sugar mass is raising by the operation of the separator at a speed necessary to cause a rise in the temp. sufficient to increase the fluidity of the molasses during the sepn. and maintaining the air in the separator in a satd. condition by the addn. of moisture.

Recovery of sucrose from sugar-beet molasses. Roy H. Cottrell and Vernal Jensen. Can. 384,347, Oct. 3, 1939. Lime is added to the molasses at a temp. below 17° to ppt. Ca sucrate, sludge obtained from a subsequent step in the process at about 80° and contg. hot Ca sucrate is added to the resulting mixt. of cold Ca sucrate and mother liquor, forming a filter-feed mixt. above 17°. The mixt. is filtered, the filtrate heated to ppt. hot Ca sucrate, the product sepd. into a sludge at about 80° and a substantially clear hot waste liquor, and the sludge added to the mixt. of cold Ca sucrate ppt. and mother liquor in a previous step of the process. An app. is described.

Crystallized glucose. Glucoseries réunies, Soc. anon. Belg. 431,954, Feb. 28, 1939. The crystals obtained from a first centrifuging are mixed with a solvent for the impurities in such proportion that the mixt. is sufficiently fluid to be centrifuged.

Treating sugar-bearing materials such as massecuite. Charles A. Olcott. U. S. 2,178,805, Nov. 7. App. is described, and various details of a method of heating sugar-bearing materials which comprises subjecting different portions of the material to the action of a heating device different portions of which are at different temps.

Dustless starch grits. Wm. J. Lauterbach (to Corn Products Refining Co.). U. S. 2,178,235, Oct. 31. Starch (preferably corn starch flushed from the tables) is heated in fluid suspension (preferably at a temp. of 65° for 10 min.) to effect requisite gelatinization and swelling without substantial cell disruption, the fluid is removed from the starch magma, the partially gelatinized starch is dried, and fines are screened out and are preferably returned to the gelatinizing tank for reprocessing. Cf. *C. A.* 33, 9702[8].

29—LEATHER AND GLUE

HENRY B. MERRILL

Recent investigations on unusual hide defects. W. Hausam, E. Liebscher and T. Schindler. *Collegium* 1939, 529–36.—A description with photographs is given of hard, flat deposits, 4–4.5 cm. wide, 8–9.5 cm. long and 1.5 mm. thick, found in a flesh split from an Argentina beef hide. The deposits were of ossified tissue similar to that often found in muscle but seldom in skin. Suc deposits are caused by various kinds of injuries. In the present instance the deposits were found to contain molds (*Aspergillus, Penicillium*) and this is suggested as the cause of their formation. Decompn. of bated beef hides at the level of the hair roots, resulting in splitting of the skin into

2 layers, was caused by infection from an old skin left for several days in the bate. The decompd. skin was slimy and foamy. A piece of good hide placed, under anaerobic conditions, on an infected hide was entirely destroyed in 24–48 hrs. A gas-forming anaerobe was isolated, which was similar to, but not identical with, the Fraenke gas bacillus. When injected into mice or guinea pigs, it did not cause hide infections or death of the animals. A mixed culture from the hide was much more active than pure cultures. There was a true symbiotic relation between the anaerobe, a coccus and *B. mycoides*. I. D. C.

Factory organization in tanning-extract manufacture. III. General organization. Josef A. Sagoschen. *Collegium* **1939**, 497–528, 536–43; cf. *C. A.* **33**, 7612[4].—Organization problems of the plant as a whole are discussed. These are divided into (1) factors affecting choice of a site for the plant, such as supply and source of raw materials, transportation, and waste disposal, (2) construction problems, including those of design, construction materials and safety, and (3) manufg. problems. I. D. Clarke

Characteristics of vegetable and synthetic tanning materials. XVI. The technological tanning properties of pine bark extracts. F. Stather, H. Herfeld and H. Schopel. *Collegium* **1939**, 561–81; cf. *C. A.* **34**, 281[8].—Dewaxing the bark before extn. did not influence the yield of tannin or case of filtration of the ext. The finer the bark was ground before extn the greater was the amt. and purity of the ext. As the extn. temp. increased, tannin and sugar in the ext. increased, but buffer capacity did not change. At 20° and 100° tannin values were 10.8 and 13.7%, resp., nontannin 8.6 and 9.9% and total sugar 1.6 and 3.2%. Fractional extn. gave fractions of about the same purity; succeeding exts. had somewhat lower buffer capacities but greater ease of salting out and combining power. Dialysis through parchment caused some improvement in purity and other properties of the ext. Sulfiting the ext. decreased insolubles, fixable tannin and ease of salting out but increased purity and amt. of tannin. Sulfited exts. gave a softer, more elastic leather. Best results for sulfiting were obtained by using 40% of a 1.1 sulfite-bisulfite mixt., based on the insolubles, and heating for 9 hrs. at 95–98°. Increasing the time of heating from 9 to 20 hrs. made little difference. At 70° sulfiting action was negligible. Use of 100% of sulfite or pressure at 125–130° gave an ext. of low purity which produced a dark, tinny leather. Sulfited exts. fermented only moderately and produced almost no acid. I. D. Clarke

Enzyme preparation from Aspergillus oryzae in the leather industry. B. G. Babakina and A. D. Zamyslov. *Biokhimiya* **4**, 316–26(1939).—Directions are given for the prepn. and use of a potent depilating enzyme from *Aspergillus oryzae*. H. Priestley

Softening of sheepskin with weak pickling solutions. V. Mikheev. *Kozhevenno-Obuvnaya Prom. S. S. S. R.* **1939**, No. 8, 28–9.—Both HOAc and weak H_2SO_4 increased the strength of the areolar tissue of sheepskin in comparison with the usual methods of treatment. The effect of HOAc was greater than that of H_2SO_4. The apparent sp. gr. decreased more with the weak H_2SO_4 than with the HOAc. The HOAc soln. contained 5 g./l. of 100% HOAc, 30 g./l. of salt, the liquid:pelt ratio being 1:4. The temp. of treatment was 35–37° and the pH was maintained automatically at 4–4.7. The H_2SO_4 soln. had 2 g./l. of 100% H_2SO_4, 5 g./l. of salt, and a liquid:pelt ratio of 1:4. The temp. was 35–37° and the pH was 3.5–4.0. The pelts which were thus softened and then chrome-tanned were lighter and had a larger tensile strength than those which were pickled by ordinary methods. B. Z. Kamich

Commercial practice and analytical methods in the production of gelatin and glue. F. W. Horst. *Gelatine, Leim, Klebstoffe* **7**, 147–57(1939).—Details of the commercial operation are discussed in relation to their effect on the quality of the product. Don Brouse

Tanning hides with iron compounds. Werner Huehn (to I. G. Farbenind. A.-G.). U. S. 2,178,102, Oct. 31. See Brit. 495,638 (*C. A.* **33**, 3628[2]).

Tanning materials. Laurence R. B. Hervey (to Arthur D. Little, Inc.). U. S. 2,178,874, Nov. 7. A sexivalent Cr compd. such as $Na_2Cr_2O_7$ is treated with an acid resistant to oxidation and of sufficient strength, such as H_2SO_4, to liberate free chromic acid and keep the trivalent Cr in soln., and the resulting product is treated with an unsatd. org. compd. such as oleic acid to produce a reaction product contg. a trivalent Cr salt.

Synthetic tanning agents. Friedrich W. Guthke (to I. G. Farbenind. A.-G.). U. S. 2,179,038, Nov. 7. Tanning agents are produced by a process which involves subjecting a water-sol. sulfonated condensation product derived from a phenol or naphthol and CH_2O or the like to an after-treatment with CH_2O or the like and a phenol or naphthol, and effecting reaction of urea and CH_2O or the like in the material. Several examples with details are given.

Synthetic tanning material. S. S. Vasserman and N. V. Otmennikov. Russ. 51,798, Sept. 30, 1937. The sulfonation product of a mixt. of crude anthracene and naphthalene is condensed with S.

Bleaching glue. Walter M. Urbain and Lloyd B. Jensen (to Industrial Patents Corp.). Can. 384,588, Oct. 10, 1939. A mixt. of KNO_3 1–2 and H_2O_2 about 0.6% based on the glue-liquor solids is agitated with the glue liquor, and then the glue liquor dried.

Unhairing hides and skins. Wm. H. Hill (to American Cyanamid Co.). U. S. 2,174,497, Sept. 26. Unhairing is effected by use of an alk. hydrolyzing agent such as $Ca(OH)_2$ or NaOH together with biguanide or guanylthiourea or other unhairing accelerator of the general formula $R'R''NC(:NH)NHC(R)NH_2$ in which either or both R′ and R″ are H or alkyl or aryl groups and R is a S atom or a NH group.

Disazo dyes for leather. Mordecai Mendoza (to Imperial Chemical Industries Ltd.). U. S. 2,177,371, Oct. 24. From components such as 4-amino-4′-nitrodiphenylamine-2′-sulfonic acid, a *m*-diamine of the benzene series, and 3-amino-5-sulfosalicylic acid, disazo dyes are produced which dye leather brown shades.

30—RUBBER AND ALLIED SUBSTANCES

DAVIS

Hevea latex of large particle size. J. McGavack. *Ind. Eng. Chem.* **31**, 1509–12(1939).—New exptl. data on the proportions of particles of various sizes in modified *Hevea* latexes are presented. Latexes were creamed, the creams were dild. to 2.5% solids, were added to gelatin soln. and then photomicrographs obtained. In some expts. the creaming and diln. were repeated several times to remove water-sol. substances as completely as possible. The smaller the proportion of creaming agent (NH_4 alginate), the larger was the av. diam. of the particles and the smaller was the amt. of rubber recoverable. Measurements of the no. of particles, total vol. and total diam. for various size intervals are tabulated and size-distribution curves given. The proportion of N retained by rubber particles in washed latexes was found to be approx. proportional to the surface area of the particles. Hence it is possible to fractionate latex into portions contg. different av. diams. of the particles and having different N values. A type of latex particularly suitable for waterproofing and insulating and which yields a highly purified rubber can thus be prepd. C. C. Davis

Tentative procedures for testing the variability of normal and concentrated latex. Crude Rubber Committee, Div. Rubber Chem., Am. Chem. Soc. *Ind. Eng. Chem., Anal. Ed.* **11**, 593–7(1939).—The procedures are offered as reliable methods of sampling; of detg. total solids, dry

rubber content, coagulum, alky., pH value, viscosity, yield point, Cu, Mn, water-sol. substances and acetone-sol. substances; and of prepg. films. The procedures do not include tolerances and are not actual specifications for purchasing and selling. C. C. Davis

Industrial sources of rubber in the U. S. S. R. A. A. Nichiporovich. *VNIIKiG and the Kauchukonos Trust. Sel'skokhozgiz* (Moscow) **1938**; *Khim. Referat. Zhur.* **2**, No. 1, 102–3 (1939).—Sources of rubber and the evaluation of different types of rubber and gutta-percha plants are described. The characteristics of the most important rubber plants, the physiology of the formation and accumulation of rubber in these plants, methods of discovery, and the detn. of rubber in the plants are given. Improved methods for different grades of rubber, and diseases are discussed. W. R. Henn

Plantation research. Herbert Ashplant. *India-Rubber J.* **98**, 585–7 (1939).—A review of recent work. C. C. Davis

German specifications for the testing of rubber. P. Kluckow. *Gummi-Ztg.* **53**, 1147–8 (1939).—A review and discussion of current approved methods. C. C. Davis

The measurement of the plasticity of rubber. Wm. M. Widenor. *India Rubber World* **101**, No. 2, 41–6 (1939).—An illustrated review of some of the important methods of measuring plasticity, with a bibliography. C. C. Davis

Application of the interferometer to the measurement of dimensional changes in rubber. Lawrence A. Wood, Norman Bekkedahl and Chauncey G. Peters. *J. Research Natl. Bur. Standards* **23**, 571–83 (1939) (Research Paper No. 1253).—The interferometer method for the measurement of small dimensional changes is adapted to soft rubber. A detailed description is given concerning the prepn. of specimens, app., procedure and calcns. Emphasis is placed on the measurement of thermal expansivity and the dimensional changes involved in transitions between different forms of rubber. The lower limit of temp. is set only by the refrigerating liquid, temps. as low as −185° being utilized. The upper limit of temp. is set only by the rubber itself. Results obtained in a study of the expansivity and transitions of "stark" (frozen) rubber are given as an illustration of the application of the method. Other possible applications are the measurement of the swelling of rubber by vapors and the detn. of stress-strain relations under compressive loads. The chief limitation of this method with rubber arises from the plastic flow of unvulcanized rubber at elevated temps. The method also has the inconvenience of requiring continuous observation. Compared with other methods of measuring small dimensional changes, the method is of advantage in its high sensitivity, the small size of the specimen required, the ease of obtaining temp. equil., the absence of a confining liquid and the simplicity of the calcns. N. B.

Dynamic fatigue life of rubber. S. M. Cadwell, R. A. Merrill, C. M. Sloman and F. L. Yost. *Ind. Eng. Chem., Anal. Ed.* **12**, 19–23 (1940).—The results of systematic and extensive expts. on the resistance of vulcanized rubber to oscillatory stresses are described, with pictures and diagrams of the equipment. For linear vibration, 4 conditions were studied: (1) compression cycles in which the max. lengths were less than the normal lengths; (2) compression-extension cycles, in which the ranges were from below to above the normal length; (3) extension cycles from normal back to normal length, and (4) extension cycles in which the min. lengths of the vibratory cycles were greater than the normal lengths. For a given length of vibratory travel, life was shortest under condition (3). For any particular min. length during vibration, the greater the vibratory travel, the shorter was the life. For given conditions of vibration, the harder the rubber the shorter in general was its life. Temp. affected the resistance to vibration, but its influence is not simple since at elevated temps. heat aging accelerates deterioration, and at subnormal temps. increased stiffness tends to shorten life. The dynamic fatigue life of rubber under a vibrational shearing stress was found to follow the same general principles found for rubber in linear vibration. C. C. Davis

Tensile properties of rubber compounds at high rates of stretch. Frank L. Roth and Wm. L. Holt. *J. Research Natl. Bur. Standards* **23**, 603–16 (1939) (Research Paper No. 1256).—The stress-strain relationships and work of extension of 4 vulcanizates were studied. The rates of stretch were great enough so that the conditions may be considered adiabatic. One mixt. was "pure gum"; the other 3 contained 25 vols. of channel black, soft black and clay, resp., per 100 vols. of rubber. The tensile properties of ring-specimens were detd. from a study of the position of the wt. as a function of time. The position of the wt. was recorded at equal intervals of time on a paper tape, 1 end of which was fixed to the wt. The tape was pulled through a spark gap as the wt. fell. The timing of the sparks was controlled by a tuning fork. Specimens were stretched to the point of rupture in about 0.5 to 0.75 sec. The work of extension was detd. as a function of the elongation of the specimen from the instantaneous positions and corresponding speeds of the wt., and from this the stress-strain relationships were obtained. A comparison of these data with similar data for a rate of stretch which lay in the range of speeds common to the usual routine tests failed to show that tensile properties measured at high rates of stretch offer any better indication of resistance to abrasive wear than the same properties measured at the usual rates. N. Bekkedahl

Rubber for pressing and forming of metals. Paul Grodzinski. *Rubber Age* (London) **20**, 269–70 (1939).—A discussion, with diagrams, of the applications of various types of rubber mixts. to various constructions. C. C. Davis

Heat formation in rubber—a method of measurement. N. N. Mikhailov and S. E. Polyak. *Caoutchouc and Rubber* (U. S. S. R.) **1939**, No. 4–5, 27–38.—The authors describe an original *app.* for measuring the amt. of heat evolved when a standard sample of rubber is subjected to a vibrational load. The app. consists of a stand with 2 columns supporting a loaded elastic beam motivated by an elec. motor through a roller-bearing eccentric. The vibrations of the beam are transferred through a ring-type dynamometer to a piston bearing on the sample. The sample is set into a cylindrical chamber in a brass block which can be raised or lowered by means of a screw for the insertion of the sample and varying of static load. Provisions are also made for heating and cooling the sample by means of a nichrome coil and copper coil for elec. current and liquid air, resp. The resonance of the system is regulated by varying the static load on the beam. The dynamometer mounts 2 mirrors, free to rotate through a small angle whose axes are at right angles. The mirrors reflect a ray of light, originating from a lantern with a very small aperture, into a recording camera. When a vibration load is applied, the light "spot" traces out an ellipse upon the photographic plate or opaque glass screen. The heat evolved by each cycle can be calcd. by measuring the area, height, breadth and distance of ellipse center from the vertical axis. Appropriate equations and formulas are given. Bernard Kilberg

Rubber and the brewing industry. J. P. Griffiths. *India-Rubber J.* **98**, 593–7, 619–24, 652–4 (1939).—An illustrated description, dealing with the various uses of rubber equipment, its maintenance (with particular reference to cleaning), specifications for quality, chem., phys. and mech. testing, etc. C. C. Davis

Sheeting; rubber. *Federal Specification* **ZZ-S-311a**, May 23, 1939. **Blankets; rubber.** *Ibid.* **ZZ-B-426**, May 23, 1939. Washington: Supt. of Documents, U. S. Govt. Printing Office, 5¢ each. L. Wilson Greene

The applications of high-frequency currents in the rubber industry. H. A. Leduc. *India-Rubber J.* **98**, 726–31 (1939).—See *C. A.* **32**, 5248[8], 6095[3]. C. C. Davis

Waste in the rubber industry. B. King. *Trans. Inst. Rubber Ind.* **15**, 125–30 (1939).—A discussion of various problems involving materials and processes. C. C. D.

Carbon-black adsorption and its effects. A review of the technical literature. Charles J. Glaser, Jr. *Rubber Age* (N. Y.) **46**, 101–2 (1939).—The conclusion is reached that the proportion of O adsorbed on C black in rubber plays

a very important part in the effect of the black on the rubber mixt. ZnO and stearic acid reduce or nullify the tendency of the adsorbed O to affect the rate of vulcanization. C. C. Davis

Pine tar as an ingredient for rubber mixtures. A. M. Ushakov. *Lesokhim. Prom*, 6, No. 1, 29–32(1938); *Khim. Referat. Zhur.* 2, No. 3, 125(1939); cf. *C. A.* 33, 4820⁷.—The moisture, ash, mech. impurities, water-sol. and volatile acids, acid no., η and flash temp. of pine tars were detd. The moisture content was detd. by settling; the upper layer of tar was analyzed for emulsified water, according to the method of Dean and Stark. The mech. impurities were found in the residue when the tar was dissolved in acetone. The ash was detd. in the residue of the volatile substances. The water-sol. acids were extd. with water by refluxing, followed by titration. The acid no. was detd. by titrating an alc.-C_6H_6 soln. of the tar (alkali blue as indicator). η was measured in a Hutchinson viscometer for dense glues. The flash temp. was detd. according to OST 7872. Investigations of different grades of crude tars in rubber showed that retort tars are superior to furnace tars and to birch dry-distn. tars. Cooked tars are better than crude tars. Increased cooking decreases moisture, water-sol. acids, volatile substances, acid no., plasticity and resistance to aging and to hardness, and increases the mech. properties. Preliminary expts. showed that the most suitable tar for tires contained: water up to 0.5%, ash up to 0.3%, volatile substances at 150° (without water) up to 5%, water-sol. acids up to 2 mg. per g. of KOH, acid no. 30–40 mg. per g. of KOH, mech. impurities 0.1–0.25%, η according to specifications. The expts. are only preliminary. W. R. Henn

Examination of a sample of sublimed litharge. J. R. Scott. *J. Rubber Research* 8, 125–9(1939).—Expts. showed that, in rubber-S-PbO mixts., sublimed PbO gave vulcanizates with mech. properties only slightly superior to those of corresponding vulcanizates prepd. with PbO made by the ordinary grinding process, and inferior to those of vulcanizates prepd. from dispersive PbO (Tegoglätte). PbO in general and sublimed PbO in particular tend to give property-time of vulcanization curves with 2 points of reversion. C. C. Davis

Effect of reclaimed rubber on temperature coefficient of vulcanization. W. S. Coe. *Ind. Eng. Chem.* 31, 1481–5 (1939).—The temp. coeffs. of vulcanization of 5 rubber mixts. contg., resp., no reclaimed rubber and 4 different types of reclaimed rubber (alkali, whole tire, acid whole tire, tread and red inner tube), were estd. on a basis of free S, T-50 test and stretch modulus data for the numerous cures for various lengths of time at different temps. The temp. coeffs. of the 4 mixts. contg. reclaimed rubber were considerably higher than the coeff. of the mixt. contg. no reclaimed rubber. The coeffs. estd. from the modulus data were lower than those estd. from free S data. The coeffs. estd. from the T-50 test data were intermediate between the values by the other 2 methods. The T-50 test method has the advantage over the other 2 methods in simplicity and rapidity and it is satisfactory for most practical purposes. The free-S method seems to be the most accurately reproducible method. Although favored by some investigators because of the greater practical significance of mech. properties, the modulus method involves considerable discretion in the establishment of proper exptl. conditions and thereby a reliable basis of comparison. C. C. Davis

Physicochemical constants of the hydrocarbon fraction used for regenerating rubber. K. Kuchinskaya and N. Panov. *Sbornik Trudov Opytnogo Zavoda im. Akad. S. V. Lebedeva* 1938, 50–2; *Khim. Referat. Zhur.* 2, No. 4, 24 (1939).—The hydrocarbon fraction, dried over $CaCl_2$ for 24 hrs. and filtered, gave d_{20} 0.8360, vapor pressure (by the dynamic method) $\log p = 7.88 - (2083.21/T)$, heat of vaporization (at 145°) 77.3 cal. per g., heat capacity at 20.5° to 150.5° $C = 0.3746 + 2 \times 0.000863t$, mol. wt. 130.06. W. R. Henn

Gutta-percha and balata. II. Collection and analysis. H. J. Stern. *Rubber Age* (London) 20, 277–80(1939); cf. *C. A.* 34, 659⁸.—Descriptive. C. C. Davis

Guayule. S. M. Mashtakov. *Caoutchouc and Rubber* (U. S. S. R.) 1939, No. 9, 36–40.—Data are given on the physicochem. characteristics of rubber extd. from 6 types of guayule. The rubber, tar and water-sol. material in the bark were 2.87–9.92, 10.74–15.31 and 21.94–27.82%, resp.; for the wood the resp. values were 0.05–2.71, 3.24–6.52 and 4.17–15.57%. The mol. wts. of the rubber varied from 21,900 to 44,000. The η of C_6H_6 solns. of the rubber decreased with decreasing concn. The tars had low acid nos. (9 to 14). B. Z. Kamich

The processing of Thiokol. O. Kölbl. *Gummi-Ztg.* 53, 1101–2, 1118, 1134–5(1939).—A discussion of mixing, calendering, extruding, bonding of Thiokol and rubber and vulcanizing in factory practice. Recipes for various types of articles made with Thiokol-A are included. C. C. D.

Determination of the heat capacities of the liquid products of synthetic-rubber production. N. Panov and I. Dadnikov. *Sbornik Trudov Opytnogo Zavoda im. Akad. S. V. Lebedeva* 1938, 36–40; *Khim. Referat. Zhur.* 2, No. 4, 24(1939).—The detns. were made by immersing a bulb contg. the substance (heated to a definite temp.) in a water calorimeter. The values obtained were: for piperylene (b. 41.6°) $C = 0.3747 + 2 \times 0.000986t + 3 \times 0.000010446t^2$; for primary BuOH (b. 116.6°) $C = 0.6053 + 2 \times 0.000488t + 3 \times 0.000002t^2$; for *sec*-BuOH (b. 110.2°) $C = 0.655 + 2 \times 0.00046t + 3 \times 0.000006124t^2$; for *sec*-AmOH (b. 138.1°) $C = 0.592 + 2 \times 0.00113t + 3 \times 0.00000042t^2$; for MeEtCO (b. 79.9°) $C = 0.4242 + 2 \times 0.00081t + 3 \times 0.00000346t^2$; for Bu_2O (b. 140.5°) $C = 0.217 + 2 \times 0.00466t + 3 \times 0.0000066t^2$. W. R. Henn

Theories of acceleration. L. B. Sebrell. *Ind. Eng. Chem.* 31, 1468–71(1939).—The various theories which have appeared during the last 31 years are reviewed (cf. *Chemistry and Technology of Rubber*, pp. 304–31; *C. A.* 31, 8993⁵).— Earlier theories attempted to explain acceleration on a purely chem. basis, whereas the trend is now toward a phys. or physicochem. basis. C. C. Davis

Temperature coefficient of vulcanization R. H. Gerke. *Ind. Eng. Chem.* 31, 1478–81(1939).—A survey of data on the temp. coeff. of vulcanization, published by various investigators, supports the view that the reaction involved in vulcanization is a chem. reaction. C. C. Davis

Low-temperature set as a measure of state of vulcanization. J. H. Fielding. *Ind. Eng. Chem., Anal. Ed.* 12, 4–9(1940).—A new method for measuring the tendency of rubber under tension to freeze is described. In its purpose it is analogous to the T-50 test of Gibbons, Gerke and Tingey (*C. A.* 27, 4438) but is simpler and more rapid, requires none of the usual scientific equipment and involves only linear measurements. Yet from a practical point of view it gives precise results. It is designated as *the 0° set test*. The sample is stretched to a predetd. elongation, is immersed in ice water for 2 min., released from tension, is held 1 min. longer in the ice water and its new length measured. The result is expressed as percentage set (based on the original length) or as fractional set (based on the initial elongation). Detailed data on representative vulcanizates are given, and the effects of various compounding ingredients are discussed. In all cases undercured samples showed relatively high sets; overcured samples showed low sets. The decrease in set was at first gradual, then rapid, then again gradual. The states of cure for which the change was rapid depended on the temp., but at 0° the rapid change was close to the so-called optimum cure (an exception was a vulcanizate contg. no S). This is fortunate from the point of view of the practical utility of the new test. There was no general and simple relation between 0° set and stretch modulus values, because the latter is influenced by many factors other than combined S. As a control test, the 0° set test should be used for the range of cure in which it is most sensitive, and actually this means over a substantial part of the curing range of the most important recipes of today. C. C. D.

Vulcanization of latex. C. E. Bradley. *Ind. Eng. Chem.* 31, 1485–8(1939).—A review of earlier and more recent developments, with particular emphasis on the practical aspects. C. C. Davis

Vulcanization from a thermodynamic viewpoint. Ira

Williams. *Ind. Eng. Chem.* **31**, 1464–8(1939).—Thermodynamic data on vulcanization have been concerned chiefly with the heat of reaction of rubber and S. A study of the change in free energy in the reaction: isoprene → natural rubber, indicates that this process is possible under suitable conditions, and an investigation of the thermodynamics of the most important side reactions might be of aid in establishing conditions for this synthesis. Furthermore a study of the free energy of the rubberlike polymer of isoprene should be of help in comparing this product with natural rubber. The properties which resemble those of vulcanized rubber which are imparted to raw rubber by the incorporation of a finely divided powder involve only a relatively small change in energy. Data on the reactions (1) chloroprene → vulcanized chloroprene polymer and (2) chloroprene → plastic polymer → vulcanized polymer, would probably throw light on the nature of the change from the plastic to the nonplastic state of this system. C. C. Davis

Effect of rubber variability on vulcanization. J. D. Hastings and Edgar Rhodes. *Ind. Eng. Chem.* **31**, 1455–60(1939).—The paper comprises a survey of past studies of the variability of plantation rubber and new expt. data on rubber tested comparatively by the old rubber-S (100·10) mixt. and by the new A. C. S. recipe (cf. Babcock, *et al.*, *C. A.* **30**, 8679[7]). The new data were obtained from 157 samples of No. 1 smoked sheet from various localities, but all were prepd. at the same time to eliminate seasonal effects. The variability of the rubber was judged by the tensile moduli of the vulcanizates. The 2 recipes gave results which are more in harmony than might be expected from criticisms of rubber-S mixts. by technologists in the past. Although perfect correlation was not found, there was in no case a reversal of the order of quality of any 2 samples when tested by the 2 recipes. Examples of variability resulting from uncontrollable causes, notably tapping systems, are shown, and the variations due to these causes are compared with those introduced by the producer during prepn., e. g., coagulant, rolling, washing, drying, smoking, etc. In conjunction with other work, the results indicate that differences in present-day methods of prepg. smoked sheet do not account for as much variability as supposed. Variability is largely a result of inherent variations in latex, including differences in the trees, soil and other environmental conditions and in estate methods. Sackett's conclusion (cf. *C. A.* **28**, 4267[5]) that the consumer must eliminate most of the variability by blending is still warranted. C. C. Davis

Control by individual incorporation of vulcanizing agents. D. F. Twiss. *Ind. Eng. Chem.* **31**, 1461–4 (1939).—The various methods of practical compounding whereby ingredients which play an active part in vulcanizing rubber are incorporated by diffusion are reviewed and discussed, with references to the journal and patent literature. The most promising method seems to be that in which a secondary amine is converted, in the presence of S and ZnO, to a dithiocarbamate ultra-accelerator, by diffusion treatment with CS_2, but which is modified by using, in place of the amine itself, a deriv. which is readily decompd. by CS_2 at room temp. within the rubber mixt. The vulcanizing activity of the accelerator formed *in situ* is increased by subsequent treatment with NH_3 or an amine or by the earlier incorporation of an org. base. These accessory compds. also accelerate the action of CS_2 on the aldehydeamine. C. C. Davis

X-ray structure of vulcanized rubber. Geo. L. Clark. *Ind. Eng. Chem.* **31**, 1397–1401(1939).—A crit. review and discussion of the work of various investigators since 1925 and of the part which x-ray data have played in studying the structure of rubber. C. C. Davis

Oxidation of vulcanized rubber. Effect of temperature, state of cure and thickness. A. R. Kemp, J. H. Ingmanson and G. S. Mueller. *Ind. Eng. Chem.* **31**, 1472–8 (1939).—Previous expts. on the rate of oxidation of vulcanized rubber at 60–80° were continued in the 100–10° range, and the results correlated with these earlier expts. (cf. I. and K., *C. A.* **32**, 9554[5]). Three mixts. were tested, contg., resp., smoked sheet 100, 100, 100; S 3, 3, 0; ZnO 20, 20, 20; di-*o*-tolylguanidine 0.75, 0.75, 0; phenyl-α-naphthylamine 0, 1, 0; tetramethylthiuram disulfide 0, 0, 3. Within the range where considerable loss of tensile strength took place, and in the temp. range 60–90°, the rate of oxidation was substantially a straight-line function of the time; at 100° and 110° this relation was no longer linear, and the rate decreased with increase in time. The higher the temp., the higher was the rate of oxidation, and at 60–110° the rate doubled with each 7.5° increase, a temp. coeff. of 2.5. The tensile strength decreased as a straight-line function of the time of aging and proportion of O consumed. The proportion of O consumed, judged by gain in wt. for 50% loss of tensile strength, depended on the temp., e. g., at 60° and at 110° the O requirements were 1.30 and 0.65%, resp., of the rubber hydrocarbon. When the vulcanizates were heated in CO_2 at 80° and 110° long enough to cause a 50% loss of tensile strength in O, the tensile strength increased, probably a result of further vulcanization. The higher the state of vulcanization the greater was the rate of oxidation, and the latter was apparently autocatalytic in overvulcanized rubber. The higher the state of vulcanization, the smaller was the proportion of O to lower the tensile strength a given amt. Variations in thickness of 0.43 1.90 mm. of vulcanizate (2) did not influence its rate of oxidation or rate of loss of tensile strength at 80° and 3.5 kg. per sq. cm. pressure of O. Vulcanizate (3) oxidized less rapidly than vulcanizates (1) and (2), but the mechanism of oxidation and deterioration was apparently the same. C. C. Davis

Cellophane [films from rubber hydrochloride] (Waterfield) **13**. C blacks and lampblacks [for use in rubber compns.] (U. S. pat. 2,178,382) **18**. Sand-blasting stencil sheet [contg. and coated with crepe rubber] (Can. pat. 385,085) **13**. Elec. cable insulation [use of rubber] (Russ. pat. 51,970) **13**.

Preserving rubber. Robert L. Sibley (to Monsanto Chemical Co.). U. S. 2,176,860, Oct. 17. Rubber is treated with about 1% of an aldehyde deriv., such as the butyl aldehyde deriv., of a ketone-phenol condensation product derived by use of acetone, Me Et ketone, cyclohexanone or Me- or Et-substituted cyclohexanone, where the ketonic O atom of the ketone is replaced by 2 *p*-hydroxy-substituted phenyl radicals.

Preserving rubber, etc. United States Rubber Products, Inc. Brit. 506,565, May 31, 1939. Rubber, unsatd. fatty oils, essential oils, petroleum oils and their derivs. such as gasolines, soaps, aldehydes, synthetic resins, etc., are preserved by incorporation of a small proportion, e. g., 0.1–5%, of an *N*-carbamyl deriv. of an amino-diarylamine of formula R′NHR″NHC(:X)NRR, wherein R′ is aryl, R″ is arylene, X is O, S or an imide radical and R is H or a hydrocarbon group. The compds. may be made, e. g., by the reaction of a carbamyl halide on a primary amino-substituted diarylamine. Among examples, (1) *p*-aminodiphenylamine is heated for 90 min. with an excess over the mol. equiv. of urea at 150° with evolution of NH_3, the molten mass is poured into H_2O with agitation and the ppt. is washed with hot H_2O and dried; the product is *p*-anilinophenylurea, and (2) *p*-aminophenyl-*p*-tolylamine is dissolved in C_6H_6 and phenyl mustard oil added; on standing, a gray powder seps. which may be washed with C_6H_6 and dried; the product is *p*-(*p*-tolylamino)diphenylthiourea. In Brit. 506,566, May 31, 1939, a carboxyalkylaminodiarylamine of formula R′NHR″-NHY, wherein R′ is aryl, R″ is arylene and Y is a carboxy-substituted alkyl group, is incorporated. The COOH group itself may be substituted. The compds. may be made, e. g., by the interaction of a primary amino-substituted diarylamine and a halo carboxylic acid or deriv. thereof. Thus, equimol. proportions of *p*-aminophenyl-*p*-tolylamine, monochloroacetic acid and anhyd. AcONa are heated together in alc. soln. for about 1 hr., the soln. then made alk. with dil. aq. NaOH and filtered, the filtrate acidified and the white ppt. formed filtered off, washed and dried.

CHEMICAL ABSTRACTS

Vol. 34 MARCH 20, 1940 No. 6

1—APPARATUS, PLANT EQUIPMENT AND UNIT OPERATIONS

W. L. BADGER

Laying out a modern industrial laboratory. Irving E. Muskat. *Chem. Industries* **45**, 531–3(1939). E. H.

Recent developments in laboratory apparatus. William 3 B. Warren and Howard Draving. *Chem. Industries* **45**, 669–73(1939). E. H.

Selection of safe metals for chemical equipment. Paul V. Faragher. *Chem. Industries* **45**, 682–4(1939). E. H.

Modification of the stirring device of the Hortvet cryoscope. W. J. Blackie and G. F. Flemons. *Analyst* **65**, 26–7(1940).—The stirring is accomplished with the aid of blowing by means of the ordinary copper water-blast 4 and filter pump and a modification of a vacuum operated wind-screen wiper. Full details are given for prepg. the app. which has been used successfully for 3 yrs. W. T. H.

A hot-wire cutter for glass tubing. A. A. Hirsch. *Ind. Eng. Chem., Anal. Ed.* **12**, 48(1940). G. G.

Removal of adhered rubber stoppers. A. J. Bailey. *Ind. Eng. Chem., Anal. Ed.* **12**, 52(1940). G. G.

Cleaning Jena glass filters. Herbert Hawley. *Analyst* **65**, 27(1940).—In the routine examn. of ghee at Guindy, Madrass, continued use of the filters with the phytosteryl, acetate test resulted in gradual clogging and the obstruction could not be removed by means of solvents. A few min. treatment with 4% HF followed by immediate washing cleared the obstruction and restored the original filtering speed. W. T. H.

Useful micro immersion filter. Christina C. Miller. 6 *J. Chem. Soc.* **1939**, 1962.—Details are given of the micro immersion filter which contains a disk 1.5 mm. thick cut from a Whatman ashless filtration accelerator; it is used in the detn. of SiO_2 and the mixed oxides of insol. silicates. C. J. West

Preparation of microscopic glass spheres. C. R. Bloomquist and A. Clark. *Ind. Eng. Chem., Anal. Ed.* **12**, 61–2(1940). G. G.

Evaporation and distillation processes in the chemical industry. B. A. Matthias. *Chem.-Ztg.* **64**, 12–14, 24–5(1940).—A review. E. H.

Distillation of nitroglycerin in vacuo. R. Vandoni and Tribot. *Mém. poudres* **29**, 206–10(1939).—For the prepn. of pure nitroglycerin for Raman spectrum study, doubly distd. glycerol was nitrated with distd. 100% HNO_3 and redistd. H_2SO_4, washed with cold H_2O, slightly ammoniacal H_2O and H_2O at 45° and vacuum dried over solid potash. Twenty-five g. of the product was distd. for 7 hrs. at 50°/0.003 mm., with a modification of the method of Chiaraviglio and Corbino (*C. A.* **8**, 2061). A. J. P.

Measurements on gases and liquids that are corrosive or difficult to handle. Fritz Kretzschmer. *Z. Ver. deut. Ing.* **84**, 25–33(1940).—A description of app. and methods for measuring pressure, content in a container, vol. of flow, and weight of corrosive, low-boiling or fermentable liquids, solns. or gases. E. H.

Conveying liquids and gases in the chemical industry. B. A. Matthias. *Chem.-Ztg.* **63**, 653–6(1939).—A review, dealing especially with pumps. 29 references. E. H.

Electrical equipment trends in the chemical industry. C. C. Levey. *Chem. Industries* **45**, 534–7(1939). E. H.

Some improvements on the apparatus of Holdheide, Huber and Stocker for determining carbon dioxide. H. Schanderl and G. Bosian. *Ber. deut. botan. Ges.* **57**, 75–83(1939); cf. *C. A.* **30**, 4195⁷. L. P. Miller

A fixed-path acoustic interferometer for the study of matter. J. C. Hubbard and I. F. Zartman. *Rev. Sci. Instruments* **10**, 382–6(1939). E. H.

Thermal manometer, a new device for recording low absolute pressures. R. S. Vincent and A. Simons. *Proc. Phys. Soc.* (London) **51**, 1003–9(1939); cf. Hickman, Hecker and Embree, *C. A.* **31**, 5642⁸.—Hg is kept boiling, by an external heater, in a Pyrex tube (76 × 2.8 cm.) connected to the system in which the pressure was to be measured and the condensation temp. of the vapor recorded by the use of a thermocouple. It is not satisfactory for following rapid fluctuations of pressure but is otherwise satisfactory in the range 0.1 to 100 mm. H. A. Frediani

An optical pyrometer for general use. J. G. Hagedoorn. *Physica* **6**, 1126–8(1939)(in English).—Details are given describing an optical pyrometer possessing a large 5 field of view, high magnification, and capacity for the measurement of the brightness of very small objects. Earl H. Brown

A new radiation pyrometer. John Strong. *J. Optical Soc. Am.* **29**, 520–30(1939).—The pyrometer described measures with a thermopile and galvanometer the emission of energy in an isolated narrow band of wave lengths centered at 8.8 μ. These radiations are isolated by successive reflections from quartz crystals. The instrument can be used to measure low as well as high temp. (0 ± 100°). John W. Knowlton

Potentiometer circuit for portable optical pyrometer. R. C. Machler. *Rev. Sci. Instruments* **10**, 386–8(1939). E. H.

Preparation of semipermeable tubes for determination of osmotic pressure. E. Blegen. *Skand. Arch. Physiol.* **81**, 8–10(1939).—A collodion tube is placed in 5% $CuSO_4$ and then in 5% $K_4Fe(CN)_6$, whereby $Cu_2Fe(CN)_6$ is pptd. These tubes may be used over a long period for osmotic-pressure detns. B. C. P. A.

Apparatus for measuring the moisture in powder by a method of entrainment. G. Fleury and H. Liegier. *Mém. poudres* **29**, 222–5(1939).—App. modification. Cf. *C. A.* **25**, 5991. A. J. Phillips

A cell adapted for conductivity measurements of protein solutions. Thomas J. Dietz. *J. Franklin Inst.* **229**, 260–3(1940).—A description of a cell, with sealed-in Pt disk electrodes of cross-sectional area equal to that of the cell, designed for use with small vols. of protein solns. and to avoid the trapping of air bubbles at the electrodes. Edward B. Sanigar

Electric temperature regulators. H. Hirst. *Elec. Engr. and Merchandiser* (Australia) **16**, 247–50(1939).—A review. Four types of regulators are considered and 9 discussed: Direct (metal) expansion regulators, resistance thermostats, contact regulators, potentiometric regulators. C. G. F.

Pressure-spring thermometers. Characteristics of the various types. L. G. Bean. *Instruments* **12**, 298–300 (1939).—A review. E. H.

Absorption refrigerators in the chemical industry. W. Niebergall. *Z. Ver. deut. Ing.* **84**, 41–7(1940).—A review with 17 references. E. H.

Milling Methods. Vol. 134. 1939. New York: Am. Inst. Mining and Metallurgical Engineers. 458 pp. 45s. Reviewed in *Chem. Eng. Mining Rev.* **32**, 128 (1939).

High-vacuum molecular distillation apparatus. Kenneth C. D. Hickman (to Distillation Products, Inc.). U. S. 2,180,050, Nov. 14. Various details of an app. with a revolving drum which may contain an electrically heated heating medium such as an animal, vegetable or mineral oil, a phthalic acid ester, molten Sn or a Bi alloy, etc. U. S. 2,180,053 relates to a vacuum distn. app. with juxtaposed vaporizing and condensing disks. U. S. 2,180,052 (Kenneth C. D. Hickman and John C. Hecker, joint inventors; to same assignee) also relates to a vacuum distn. app. with rotating vaporizing and condensing plates, etc.

Distilling liquids of high boiling point. Karl Sondermann (to American Lurgi Corp.). U. S. 2,179,833, Nov. 14. App. is described, and a method of distg. liquids having relatively high b. ps. including fatty acids and glycerol which comprises establishing a body of liquid to be distd. in a suitable vessel, heating the body of liquid to distn. temps., subjecting the liquid to agitation and vertical circulation, establishing a second body of liquid within the vessel from a portion of the agitated and vertically circulated liquid, subjecting the second body of liquid to heat to finish the distn thereof, collecting vapors from both bodies of liquid in a common vapor space, and withdrawing distn. residues from the second body of liquid.

Gas and liquid contact apparatus suitable for use in fractional distillations. Arthur J. V. Underwood. U. S. 2,180,888, Nov. 21. Various structural and operative details.

Balances for analytical work. Baird & Tatlock (London) Ltd. and Hans J. Fuchs. Brit. 506,747, June 2, 1939.

Pressure fillers for pipets. Harold W. Gardner. Brit. 506,779, June 5, 1939.

Mixing and beating apparatus for large batches of materials. Walter F. Dehuff (to American Machine & Foundry Co.). U. S. 2,181,078–9, Nov. 21. Various structural, mech. and operative details.

Apparatus suitable for control of mixing operations. Yves A. Bouget and John N. Selvig (to Western Elec. Co.). U. S. 2,180,393, Nov. 21. Various details of an app. suitable for use in mixing fibrous pulp material with water for insulating wire, etc.

Float-operated device for controlling the level of liquids such as those in tanks. Edward T. Dahl (to Mason-Neilan Regulator Co.). U. S. 2,180,844, Nov. 21. Various structural, mech. and operative details.

Extensometer. Jens Sivertsen (to Tinius Olsen Testing Machine Co.). U. S. 2,180,175, Nov. 14. Various details of app. suitable for measuring changes in the length of specimens such as those of steel.

Hydrometer. Charles Nurnberg. U. S. 2,180,995, Nov. 21. Various structural details.

Adsorption apparatus for recovering solvent vapors from air. Leonard A. Logan (to Carbide and Carbon Chemicals Corp.). U. S. 2,180,712, Nov. 21. Various structural and operative details of an app. suitable for use with granular activated carbon as an absorbent material. Cf. *C. A.* **34**, 663[3].

Apparatus for controlling the pressure of fluids such as steam or oil vapors. James Briscoe (to Manning, Maxwell & Moore Inc.). U. S. 2,180,395, Nov. 21. Various structural, mech. and operative details.

Tank, etc., suitable for use in shipping natural gas, hydrogen, helium, etc. Carleton O. Booth. U. S. 2,179,682, Nov. 14. Various structural features.

Adsorber apparatus for solvent-vapor recovery. Robert H. Osterloh and William L. Scarborough (to E. I. du Pont de Nemours & Co.). U. S. 2,180,119, Nov. 14. Various structural details.

Dispensing container for vaporizable materials such as insecticides. Harold T. Weiss. U. S. 2,180,752, Nov. 21. Various structural details.

Gas-analyzing apparatus. Philip T. Sprague, Charles A. Sprague and Arnold Soller. U. S. 2,179,867, Nov. 14. Various structural and operative details of an app. suitable for use with liquids for absorbing O, CO_2 or SO_2 from mixed gases.

Liquefaction and separation of gases such as those of the air. Adolf Messer. U. S. 2,180,715, Nov. 21. App. is described, and a method of reducing the starting time of an intermittently operated air-sepg. plant of the type which includes a rectification column, which comprises storing a portion of the liquid O formed by the plant during its normal operating period in a sep. storage tank, and permitting the liquid O to evap. in the rectification column during a normal shutdown period, to maintain the column cold.

Apparatus for handling and delivery of normally gaseous material such as liquefied oxygen. Wm. F. Mesinger (to Linde Air Products Co.). U. S. 2,180,090, Nov. 14. Various structural and operative details.

Device for delivering measured quantities of liquids such as oils, etc. Frederick W. Berwick and Albert G. Berwick (to De Laval Separator Co.). U. S. 2,180,702, Nov. 21. Various structural, mech. and operative details.

Apparatus for maintaining a constant hydrostatic pressure upon liquids such as those undergoing polymerization in molds. Charles M. Fields and Reuben T. Fields (to E. I. du Pont de Nemours & Co.). U. S. 2,180,818, Nov. 21. Various structural, mech. and operative details.

Tube thermometers containing fluids such as mercury. Charles R. Palmer (to The Palmer Co.). U. S. 2,180,285, Nov. 14. Various details of structure and color striping.

Glass-tube thermometer. Wm. M. Young (to Taylor Instrument Companies). U. S. 2,179,773, Nov. 14. Various structural details.

Thermocouple. Raymond R. Ridgway (to Norton Co.). Can. 386,183, Jan. 9, 1940. Structural details are described of a thermocouple having contact elements of B_4C and graphite.

Catalytic devices for gas burners. The Gas Light and Coke Co., John A. Brigg and Ernest W. Voice. Brit. 507,083, June 9, 1939. A substance, e. g., PbO_2, that removes oxides of S from air or gases coming into contact with the catalyst is provided in the neighborhood of the catalyst. A moisture-absorbing material, e. g., SiO_2-gel or Al_2O_3-gel, may also be provided.

Portable gas-testing device suitable for determining carbon dioxide in furnace gases. Frank W. Dwyer. U. S. 2,181,013, Nov. 21. A small portable gas-testing app. comprises a block of transparent material having a caustic soln. container therein, a pressure gage therein, means for placing the gage and receptacle in communication, means including a single sliding valve for admitting gas into and permitting its discharge from the receptacle, means for intermixing the gas and soln. and a graduated

scale for indicating the percentage of CO_2 in a given sample of gas introduced through the valve. 1

Tube and header heat-exchange apparatus suitable for heating or cooling air. Lawrence C. Soule (to Carrier Corp.). U. S. 2,180,854, Nov. 21. Various structural details.

Production and handling of liquefied carbon dioxide. Eric Geertz and Jesse E. Taylor (to Cardox Corp.). U. S. 2,180,231, Nov. 14. An arrangement of app. is described, and a method of handling a liquefied gas which must be maintained above 75 lb. per sq. in. pressure to maintain it as a liquid comprising passing the gas through a plurality of stages of compression, cooling the gas after each stage of compression to remove the heat absorbed by the gas, condensing the compressed gas to obtain liquid, lowering the temp. and pressure of the liquid to a predetd. selected sub-atm temp and its corresponding vapor pressure, which will be above 75 lb. per sq. in., and delivering the low-temp., low-pressure liquid without change in temp. and pressure to an insulated container charged with a fluid at a pressure which will prevent the pressure of the incoming liquid from dropping below 75 lb. per sq. in. 2 3

Refrigerating apparatus suitable for use with sulfur dioxide, etc. Frederick W. Binns (to Virginia Smelting Co.). U. S. 2,180,624, Nov. 21. Various structural and operative details of an app. in which a refrigerant such as SO_2 and a stable heat-exchange medium such as a salt brine are used.

Apparatus for generating acetylene from calcium carbide and water. Hermann Holler and Otto Mues (to I. G. Farbenind. A.-G.). U. S. 2,180,085, Nov. 14. An app. in which the quantity of water added is limited so that a pulverulent residue is obtained includes at least one revolving screen for the reception of the Ca carbide to be gasified, a water inlet pipe arranged above the axis of each revolving screen and having at least one exit opening so that only the carbide within this screen is moistened, at least one revolving plate mounted below the revolving screen and at least one means mounted above the plate for moving the reacting material over the plates and a casing enclosing all the aforesaid parts. 4

A solution supersaturated at its boiling point. Lawrence H. Amundsen. *Rept. New Engl. Assoc. Chem. Teachers* **41**, 73(1939).—A lecture demonstration. A soln. of 2,3-dihydro-5,6-diphenylpyrazine, supersatd. at its b. p., can be prepd. by boiling for 15 min. or longer a soln. of 100 g. benzil and 45 cc. of 68% ethylenediamine in 300 cc. of 95% EtOH. Crystn. is induced by adding a crystal of the compd. or by scratching the inside of the container. If the source of heat is removed and boiling allowed to cease before inducing crystn. the soln. boils again when crystn. takes place because of the heat evolved by the process. Leopold Scheflan

Some old chemistry books. Edward R. Atkinson. *Rept. New Engl. Assoc. Chem. Teachers* **41**, 84(1939).—The book *Coelum Philosophorum* by Philipp Ulstad (1527) is definitely alchem. in nature and deals with the prepn. of various medicinals. *A Comparative View of the Phlogistic and Antiphlogistic Theories* by William Higgins (1789) constitutes a vigorous expt. support of Lavoisier's principles and in it the at. hypothesis is arrived at following an understanding of what is now called the law of multiple proportions; this was 12 years prior to Dalton's earliest

work on this subject. *Experiments and Observations on the Atomic Theory* by William Higgins (1814) was written by the author to retain the credit due him as the first to apply the at. hypothesis to chemistry. L. S.

The physics and chemistry of estuarine waters in Chesapeake Bay. Curtis L. Newcombe, Wm. A. Horne and Boland B. Shepherd. *J. Marine Research, Sears Foundation Marine Research* 2, 87–116(1939); cf. *C. A.* 32, 8642[3]; 33, 9061[2].—The Chesapeake Bay waters in the region of Solomons Island, Md., were studied during June, 1936–June, 1938. The temps. in the summer, Oct., 1st week of Dec., Jan.-Feb. and middle of June are approx. 25, 15, 7, 3–4 and 20°, resp. The variation from surface to bottom rarely exceeds 4° and for long periods between Sept. and June it is only about 1–2°. In winter the temps. are often continuously lower at the surface than at the bottom. The hourly changes are usually less than 0.5°. The annual chlorinity at Station 1 (about 38° 18′ N. lat. and 76° 25′ W. long.) varied from 0.581 to 1.023% at the surface and from 0.886 to 1.250% at the bottom. During the summer, at about 10 or 14 m., there is usually an abrupt graduation from the less dense surface waters to the bottom stratum of heavier water possessing a relatively uniform chlorinity. The O satn. is as high as 150% in Jan., probably due to phytoplankton abundance, and as low as 33% in summer, perhaps due to the mixing of bottom with surface waters. The very low O concn. in the bottom waters over relatively large deep areas of the bay during June-Sept. is significant. Surface waters unusually low in O are considered to have their origin in the deeper areas of the bay. Secchi disk readings, though subject to error, reveal marked seasonal, as well as horizontal, variations from the bay up the Patuxent River. The extent of the seasonal variations in the bay is about 2.3 m. and the max. bay-river variations about 3.2 m. The phosphate content of the bay waters in summer is commonly as high as 0.23×10^{-3} mg. atoms P/l. at the surface and 1.0×10^{-3} mg. atoms in the bottom waters. The av. concn. is about 0.95×10^{-3} mg. atoms P/l. in the waters at the upper stations in the Patuxent River. Min. concns. occur during the winter when turbidity is min. and the abundance of phytoplankton organisms is max. The nitrite concn. varies from 0 to 0.6×10^{-3} mg. atoms NO_2-N/l. The bottom concns., occasionally as high as 1.1×10^{-3} mg. atoms/l., are higher than the surface values. Zero values are frequently found in the surface layers of the Chesapeake area in early summer. During the summer the NH_3-N varies from 0 to over 8.0×10^{-3} mg. atoms/l.; local variations are pronounced. Although the Chesapeake waters are apparently much richer in NH_3-N than ocean water, the local N cycles must be studied before definite conclusions can be reached. The waters in the upper reaches of the Patuxent River during the summer contain as much as $50–116 \times 10^{-3}$ mg. atoms Si/l. The concns. at the lower river stations and in the bay commonly range around $20–30 \times 10^{-3}$ mg. atoms Si/l.

Ruth Berggren

Chemical studies of the western Pacific Ocean. V. The vertical variation of minor constituents in the "Kurosio" region. 1. Yasuo Miyake. *Bull. Chem. Soc. Japan* 14, 461–6(1939); cf. *C. A.* 33, 8063[5].—Variation of temp., chlorinity, d., and dissolved O in the Japan Current followed in general its structure: (a) a homogeneous surface layer of 100 m. with temp. 18°, chlorinity 19.23, d. 1.0251 and 5 ml. of O/l.; (b) the main part of the "Kurosio" at about 100 to 150 m., with temp. 15.2°, chlorinity 19.15, d. 25.65 and 4.34 ml. O/l.; (c) the subarctic intermediate water between 150 m. and 700 m., with diminishing temp., chlorinity and O, but increasing d.; (d) the deep water (studied between 700 and 1000 m.), with decreasing temp. and O, and increasing chlorinity and d. The O min. reported elsewhere at 700 m. was not found here. The pH diminished gradually from 8.25 at the surface to 7.78 at 1000 m. **VI. The vertical variation of minor constituents of the "Kurosio" region. 2.** *Ibid.* 467–71.—Silicate content (as Si) varied with structure increasing from 0.2 mg./l. in the surface layer to 2.28 mg./l. at 1000 m. The low values, as compared with those of the California Current, are attributed to the vertical stability of the "Kurosio." Phosphate (as P) increased from 2.0 γ/l. at the surface to 11.7 γ/l. at 1000 m., following a staggered curve. The max. reported elsewhere at 700 m. was not found here. B content increased slightly from 4.61 mg./kg. at the surface to 5.44 mg./kg. at 1000 m. Cu content was shown to increase a hundredfold, but the possibility of contamination from the Nansen water bottles necessitates further study. No appreciable vertical variation of F was found.

Wm. E. Trout, Jr.

Aluminum reflectors. A. G. C. Gwyer and N. D. Pullen. *Metallurgia* 21, 57–60(1939); *Metal Ind.* (London) 56, No. 1, 7–10; No. 2, 33–5(1940).—In Al treated by the Brytal anodic process a min. in reflectivity occurs at 3 μ. This is at the wave length of max. absorption by water and suggests that the min. reflectivity of the treated Al is caused by absorption by water in the anodic film. When films were heated and waxed while hot or heated in oil the min. reflectivity at 3 μ did not occur and reflectivity was high for all wave lengths investigated.

J. L. Gregg

Isotopes as a tool in chemical research. Joseph Joffe. *Newark Eng. Notes* 3, No. 1, 10–11(1939).—A review.

Leopold Scheflan

Volta effect and the periodic system of the elements. O. Scarpa. *Atti accad. Lincei, Classe sci. fis., mat. nat.* 29, 273–6(1939).—The Volta effects referred to as contact potential and referred to brass in the *Critical Tables*, are detd. with reference to Pt. Values reported are K 2.84, Na 2.39, Hg 1.13, Mg 1.04, Al 1.01, Zn 0.95, Cd 0.91, Pb 0.74, Sn 0.66, Sb 0.49, Ni 0.43, Bi 0.41, Fe 0.38, Cu 0.19, Au 0.07, and Ag 0.04 volts. Plotted against at. nos., these values fall into periods corresponding to their positions in the Mendeleev system. A. W. C.

Chemical force as the action of a matter field. F. Hund. *Ann. Physik* 36, 319–27(1939).—Math. H. C. T.

The determination of internuclear distances and of dissociation energies from force constants. G. B. B. M. Sutherland. *J. Chem. Phys.* 8, 161–4(1940).—Math.-theoretical. G. M. Petty

Calculation of force constants in some methyl compounds. J. W. Linnett. *J. Chem. Phys.* 8, 91–8(1940).—Force-const. calcns. on C_2H_6, the Me halides, MeCN and MeNC are described. The potential function used is based on a valency type force field with the introduction of one cross term rendered likely by phys. considerations. The applicability of this function to the mols. under consideration is tested with C_2H_6. The C–C bond force const. in MeCN is considerably greater than in C_2H_6 indicating that the bond has some double-bond character in the cyanide, as has been suggested by Pauling, Springall and Palmer (*C. A.* 33, 4480[7]). The bending const. of the HCH angle remains const. in the 4 Me halides, there being changes, however, on passing to the other compds. Other variations in the force consts. of corresponding links, similar to these, are studied and their significance discussed. G. M. Petty

Directed valence. George E. Kimball. *J. Chem. Phys.* 8, 188–98(1940).—The problem is treated from a group-theory point of view. G. M. Petty

Magnitude of the coördination numbers and the chemical formulas of complex compounds. B. Ormont. *J. Phys. Chem.* (U. S. S. R.) 13, 646–50(1939); *Acta Physicochim. U. R. S. S.* 11, 87–96(1939)(in English).—Theoretical. The inadequacies of present theories of coördination nos. as regards the description of the formation of stable configurations and the actual structure in crystals are discussed and rules to correct these defects are suggested. F. H. Rathmann

Dimensions of the phosphine and arsine molecules and the possibility of optically active derivatives. G. B. B. M. Sutherland, E. Lee and Cheng-Kai Wu. *Trans. Faraday Soc.* 35, 1373–9(1939).—Assuming the valence force field to det. the apical angle from purely vibrational data, the following dimensions are given for PH_3 and AsH_3, resp.: XH band: 1.46 and 1.56 A.; XHX angle:

99° and 97°; the height of the pyramid: 0.67 and 0.75 A. The height of the barrier restricting the passage of the P atom through the plane of the H atoms is detd. to be about the same as in NH_3; the frequency is, however, roughly 1000 times less. From a study of PD_3 it is suggested that the substitution of large groups in place of the H atoms might produce a mol. for which the frequency of inversion is sufficiently slow to enable optically active isomers to be sepd. at low temps. Victor R. Deitz 1

Effect of the restriction of rotation and of anisotropy of the internal field on the polarization of liquids. A. Peterlin and H. A. Stuart. *Z. Physik* **113**, 663–96(1939).—The combined effects of restriction of rotation and anisotropy of the internal field on the polarization and artificial double refraction are calcd. for pure liquids with polar and non-polar mols. and dil. solns. Though the theory represents the exptl. results in some cases, in others (particularly those involving magnetic double refraction) the agreement is poor. Other factors than those considered here must be included. E. J. Rosenbaum 2

Physicochemical study of the ozonides of ethyl cinnamate and of styrene. Raman spectrum, ultraviolet absorption, heat of ozonization, dielectric constant and dipole moment. E. Briner, A. Gelbert and F. Perrottet. *Helv. Chim. Acta* **22**, 1491–6(1939) (in French); cf. *C. A.* **32**, 4419[7]; **33**, 8068[8].—The Raman spectrum of the ozonide of PhCH:$CHCO_2Et$ (I) presents lines peculiar to other ozonides, as well as an intense frequency characteristic of the double bond. The ultraviolet absorption of I is apparently not modified as much by ozonization as that of other compds. studied. The heat of ozonization of I, detd. by a direct method, is 94 Cal. Ozonization does not change perceptibly the dielec. const. and dipole moment of I; this indicates that the elec. symmetry of this substance is not notably affected by the fixation of 3 atoms of O. Because of its instability, measurements on the ozonide of PhCH:CH_2 did not give satisfactory results. Ruth Berggren 3

The magnetic susceptibility of silver subfluoride. Simon Freed, Nathan Sugarman and Richard P. Metcalf. *J. Chem. Phys.* **8**, 225–6(1940).—The molal susceptibility of Ag_2F is -64.3 ± 1.2 e. m. u. $\times 10^{-6}$ both at 24°C. and at 77°K. Conduction electrons contribute a considerable diamagnetism which is related to the anisotropy of the crystals. G. M. Petty 4

Magnetic susceptibility of nickel chloride. H. R. Nettleton and S. Sugden. *Proc. Roy. Soc.* (London) **A173**, 313–23(1939).—Since the susceptibility of $NiCl_2$ in aq. solns. is const. over a wide range of concns., and the Ni content of a soln. can be detd. accurately by well-known methods, this compd. is a suitable reference standard for susceptibility work. The Gouy method was used to det. with high precision the susceptibilities of 2 aq. solns. of $NiCl_2$ of different concns. The av. mol. susceptibility at 20° ($\times 10^6$) is 4436 ± 12. Full exptl. and theoretical details are given. W. W. Stifler 5

Magnetic susceptibilities of some cupric salts. James Reekie. *Proc. Roy. Soc.* (London) **A173**, 367–78(1939).—The Gouy method was used to measure the mass susceptibilities of powd. $CuSO_4.5H_2O$, $CuSO_4.K_2SO_4.6H_2O$, and $CuSO_4.(NH_4)_2SO_4.6H_2O$ from room temp. down to 1.6°K. Throughout this entire region $CuSO_4.5H_2O$ follows the Curie-Weiss law in the form $\chi_M'(T + 0.7) = 0.4595$. Both of the double sulfates follow the Curie-Weiss law in the form, $\chi_M'(T - 0.3) = \text{const.}$, down to 14°K., but in the liquid-He region they obey the simple Curie law. The satn. moments of the Cu^{++} ion in the 3 crystals are calcd. as 1.923, 1.917 and 1.907 Bohr magnetons, resp. The theoretical interpretation of these results is discussed and it is shown that while Jordahl's cryst. field theory (*C. A.* **28**, 3284[3]) accounts satisfactorily for the behavior of the double sulfates, it does not give an adequate explanation of the results for $CuSO_4.5H_2O$. Apparently either the system of energy levels of the Cu^{++} ion in the simple sulfate is quite different from that in the double sulfates or else the effects of magnetic interaction become appreciable at relatively high temps. W. W. Stifler 6

Magnetic studies of solid solutions. I. Methods of observations and preliminary results on the precipitation of iron from copper. F. Bitter and A. R. Kaufmann. *Phys. Rev.* **56**, 1044–51(1939).—One of the new Fe-free magnets in the magnetic laboratory at M. I. T. (*Rev. Sci. Instruments* **10**, 373–81(1939)) was used to study alloys of Cu, contg. up to 0.7% Fe, at temps. from 20° to 1000°. Magnetization curves for fields up to 40,000 gausses were obtained, chiefly by the Curie method, although the Gouy method was used in some cases. The Fe atoms in soln. seem to retain a permanent magnetic moment of approx. 3.5 Bohr magnetons. The Curie-Weiss law is followed at high temps. For an alloy contg. 0.7% Fe by weight, the Curie point is 150°K. The behavior of this soln. is sluggish and it can be supercooled by 100°. The manner of pptn. of the Fe from the soln. is complex. Apparently there is a rearrangement of the atoms in the soln., followed by a pptn. of a non-magnetic phase. By cold working this is converted into a ferromagnetic phase which can be made to grow thermally although it does not seem to grow readily of its own accord. Powder compacts did not give as satisfactory results as cast samples. The theory and methods of measurement are given in some detail. W. W. Stifler 7

Dependency on size of the diamagnetic susceptibility of quartz. Yosomatu Simizu and Noboru Takatori. *Science Repts. Tohoku Imp. Univ.*, K. Honda Anniversary Vol., First Ser., **1936**, 306–11; *Neues Jahrb. Mineral., Geol.* Ref. I, **1939**, 660.—The diamagnetic susceptibility of powd. quartz decreases appreciably with decreasing size of the grains. C. A. Silberrad 8

Paramagnetic dispersion in iron ammonium alum. P. Teunissen and C. J. Gorter. *Physica* **6**, 1113–22(1939) (in English); cf. *C. A.* **33**, 2005[2], 8460[9].—The app. previously used to study the paramagnetic dispersion in Fe NH_4 alum was modified so that the high-frequency coils were inside the Dewar flask, instead of surrounding it. This change made it possible to increase the range of frequencies from $0.2 - 3.8 \times 10^6$ cycles, previously used, to $0.095 - 7.0 \times 10^6$ cycles. The new results lead to a revision of some of the conclusions previously deduced, and now agree well with the equation based on the concept of spin temp. No pos. evidence of anisotropy in dispersion in the crystal was found. Apparently the concept of spin temp. is applicable to magnetic fields well above those provided for in the theory. A discussion of the dependence of the relaxation consts. on temp. shows that the description of the thermal motion of the crystal lattice by one Debye-temp. is too simple to account for the observed phenomena. W. W. Stifler 9

Paramagnetism of the rare earths. B. Cabrera. *J. chim. phys.* **36**, 237–55(1939).—The theory of the paramagnetism of the cations of the rare earths is outlined and the phys. interpretation of the consts. introduced in the various modifications of the simple Curie law is discussed. The results of many expts., extending over several years, on the oxides, anhyd. sulfates, and octahydrates of Gd, Tb, Dy, Ho and Er are summarized without details of the actual measurements. These cations all obey the Curie-Weiss law. The chief conclusions are given in the table 10

Cation	No. of expts.	Magnetic moment	No. of Weiss magnetons
Gd^{+++}	113	44,150	39.06
Dy^{+++}	121	58,980	52.19
Ho^{+++}	65	58,520	51.78
Er^{+++}	90	53,080	46.96
Tb^{+++}	36	?	?

The value of the Weiss magneton is taken as 1130.3. While some data are given for Tb, the results are not concordant. Since measurements of χ at different temps. were made without disturbing the specimen, the relative values of χ, which give the law of variation with temp., are probably 10 times as reliable as the abs. value. W. W. Stifler 11

The electric quadripole and magnetic dipole moments of Li^6 and N^{14}. M. E. Rose. *Phys. Rev.* **56**, 1064(1939).—Theoretical. G. M. Petty 12

Dipole-dipole resonance forces. G. W. King and J. H. Van Vleck. *Phys. Rev.* **55**, 1165–72(1939).—Math.-theoretical. The sign and size of the dipole-dipole resonance energy which obeys the inverse-cube law are detd. Sp. calcns. are made and curves of energy vs. distance are drawn for H, Na, Cd and Hg. G. M. Petty

The dipole moments and structures of chlorine compounds of germanium, chromium, selenium and tellurium. C. P. Smyth, A. J. Grossman and S. R. Ginsburg. *J. Am. Chem. Soc.* **62**, 192–5(1940).—The dipole moment of GeH_3Cl was measured in the vapor state and the moments of CrO_2Cl_2, Ph_2SeCl_2 and $TeCl_4$ were measured in soln. The ratio of the moment of GeH_3Cl to the previously published value of GeH_3Cl_2 (cf. *C. A.* **34**, 2974) shows that the large size of the Ge atom largely eliminates induction between 2 Cl atoms attached to it. The considerable value of the moment of the mol. shows that the Ge-Cl bond moment is about 2 or greater than this by the amount of the small Ge-H moment. The very small moment of CrO_2Cl_2 shows that the Cr-Cl bond is of the same magnitude as the more or less semipolar Cr-O moment and probably as large as 3. The large moments found for Ph_2SeCl_2 and $TeCl_4$ indicate unsym. tetrahedral structures for their mols. The Se-Cl and Te-Cl bond moments necessary to produce such moments are much larger than those calcd. as the electronegativity differences between the elements. A. B. Garrett

Frictional dispersion of the dielectric constants of organic liquids at very high frequencies ($\lambda = 15$ cm.). R. Odenwald. *Ann. Physik* **35**, 690–700(1939); cf. *C. A.* **33**, 1778, 9085, 32227.—Measurements of the dielec. consts. of $PhNO_2$ dissolved in Shell oil *K20* as a function of concn. and temp. are extended to higher frequencies ($\lambda = 14.86$ cm.). The results agree with the Debye dipole theory. E. O. Wrig

The effect of solvent on the internal rotation of carbonic ester. Masasi Yasumi. *J. Chem. Soc. Japan* **60**, 1208–14 (1939).—The dipole moments of dimethylcarbonate and diethylcarbonate were measured in the solvents benzene, hexane and butane in the temp. range −40° to +70°. The dipole moments increase with increase in temp. This phenomenon is considered theoretically. T. K.

Dielectric evidence of molecular rotation in the crystals of certain nonaromatic compounds. Addison H. White and W. S. Bishop. *J. Am. Chem. Soc.* **62**, 8–16(1940).—Dielec. const. data are given for 2 derivs. of C_2H_6, 1 deriv. of cyclopentane, 5 derivs. of cyclohexane, and 13 derivs. of camphane. In most of these solids the dielec. const. rises abruptly at a transition, as temp. is increased, to a value characteristic of polar compds. These and other data (cf. *C. A.* **31**, 6943[1]) constitute convincing evidence that extensive rotational motion of large org. mols. is much more commonly found in crystals than has been suspected. This is more frequently found among the derivs. of cyclic polymethylenes than among the generality of org. compds., whose polarizations have normally been found to be so low in the solid state as to be ascribed to distortional effects only. The most significant phys. characteristic of these crystals in which there is mol. rotation is their low heat of fusion. It appears likely that among these nonaromatic compds. very low heat of fusion is more immediately assocd. with the ability of a mol. to rotate in the crystal lattice than with its spherical shape. For rotation in the crystal to be possible, however, a certain degree of either spherical or circular geometrical symmetry obviously is required of the mol., and its center of figure should not be displaced too far from its center of gravity. A. B. Garrett

Dielectric evidence of molecular rotation in the crystals of certain benzene derivatives. Addison H. White, B. S. Biggs and S. O. Morgan. *J. Am. Chem. Soc.* **62**, 16–25 (1940).—These dielec.-const. measurements show that mol. rotation may occur in the cryst. form of benzene derivs. as well as in aliphatic compds., provided certain requirements of symmetry are met. These data represent an extension of the ideas of the importance of symmetry (cf. *C. A.* **31**, 6943[1]) to a new class of compds., substituted benzenes, which are geometrically sym. about one axis, but electrically assym. Two kinds of evidence of molecular rotation in certain aromatic crystals are obtained: (1) The dielec. const. behaves like that of the corresponding liquid, and (2) among these solids, ϵ may be correlated with the dipole moment of the mol. Although each of the mols. involved possesses considerable volumetric symmetry about one axis through its center of gravity, the less sym. of them cease rotating abruptly at transitions, while the more sym. exhibit reduced frequency of rotation but no transitions as the temp. declines. A. B. Garrett

Investigation of the dielectric losses in the mixtures nitrobenzene–benzene and ethyl alcohol–benzene. G. M. Panchenkov and O. K. Davtyan. *J. Phys. Chem.* (U. S. S. R.) **13**, 651–9(1939).—The tangent of the angle of dipolar loss of the systems EtOH–benzene (I) and $PhNO_2$–benzene (II) varies with concns. parallel with the change of mol. polarization; tan δ_{12} increases to a max. at 50% EtOH and 80% $PhNO_2$ in I and II, resp. The values of tan $\delta_2 \times 10^3$ for EtOH rise from 60 at 0%, to 81 at 40% and then fall to 40 at 100% EtOH; for $PhNO_2$ the value of tan $\delta_2 \times 10^3$ decreases continuously from 210 to 23. Values of the time of relaxation, τ, calcd. from the equation $\tau = 6\Delta\eta/-5kT$, as derived from the Einstein viscosity equation, are obtained from the viscosities of the mixts. and found to give values of the mol. radius half as great as obtained from the dielec. data. The discrepancy is explained as due to the rotation of the mols. contg. a terminal polar group. F. H. Rathmann

Polar structure of some benzein indicators. Myron A. Elliott and S. F. Acree. *J. Research Natl. Bur. Standards* **23**, 675–81(1939)(Research Paper No. 1263).—The dipole moments of α-naphtholbenzein and thymolbenzein in benzene soln. are 4.3×10^{-18} and 6.8×10^{-18} e. s. u., resp. The values are much lower than would be expected from the conventional static dipolar structure of mols. of the benzein type. It is suggested that there is resonance in the quinone-phenolate anion between at least 2 structures. One of these should have a dipole moment of about 3.9×10^{-18} e. s. u., and hence this type must predominate in the benzein derivs. studied. S. Glasstone

Note on the viscosity of gases and molecular mean free path. A. E. Schuil. *Phil. Mag.* **28**, 679–84(1939).—The viscosity data for a no. of gases are compiled and tabulated (54 references). From these values mean free paths and mol. diams. are calcd. E. J. Rosenbaum

Supersonic effects of water vapor in carbon dioxide and their relation to molecular vibrations. W. H. Pielemeier, H. L. Saxton and D. Telfair. *J. Chem. Phys.* **8**, 106–15 (1940). G. M. Petty

Virtual entropy of silicon tetrafluoride, calculated from the molecular constants. I. G. Ryss. *Compt. rend. acad. sci. U. R. S. S.* **24**, 568–9(1939)(in German).—Using the available electron diffraction, Raman and infrared data, the entropy (translational, rotational and vibrational) of gaseous SiF_4 was calcd. as follows (°K., entropy in cal./degree mol.): 298.2°, 67.439; 373.2°, 71.560; 400°, 72.876; 473.2°, 76.347; 500°, 77.476; and 573.2°, 80.494. In the above calcns., the Si-F distance was taken as 1.55 A. (cf. Braune and Pinnow, *C. A.* **31**, 4177[9]); if the distance is taken as 1.54 A. (cf. Brockway and Wall, *C. A.* **29**, 995[1]), the above entropy values must each be diminished by 0.039 cal./degree mol. The error in the calcd. entropy values is probably less than ±0.5 cal./degree mol. George Ayers

The entropy of long-chain compounds in the gaseous state. Maurice L. Huggins. *J. Chem. Phys.* **8**, 181–7 (1940); cf. *C. A.* **34**, 7071.—Equations are derived for the entropy of long-chain normal hydrocarbons in the gaseous state at 25°. (1) The translational entropy, computed classically, varies with chain length according to the relation $S_t = a + b \ln n$. (2) The entropy of rotation of the mol. as a whole, calcd. statistically, assuming either a ball-like mol. or absolutely random kinking, is also linear with respect to $\ln n$. (3) The entropy of internal vibrations, assumed (following Pitzer, *C. A.* **31**, 4863[9]) to be an additive function of contributions assocd. with the various types of bonds and bond angles present, obeys the equation $S_{iv} = a + bn$. (4) The entropy of internal randomness, for randomly kinked mols. with no rotation, with hindered

rotation, or with completely free rotation, is likewise linear in n. The equation deduced for long-chain paraffins, contg. but one adjustable const. (connected with the degree of hindrance of the rotation about the C-C bonds) agrees well with values deduced from sp. heat data for short-chain paraffins. G. M. Petty

Compressibilities and expansion coefficients of gases at low pressures, and their relation to molecular volume. J. B. M. Coppock. *Proc. Roy. Soc.* (London) **A173**, 201–11(1939).—A simple method is described for expressing compressibilities and related low-pressure data for non-polar gases in terms of their effective mol. vols. There is a linear relation between the compressibilities and expansion coeffs. and the corresponding mol. vols. for non-polar gases. The deviations of the polar gases from the linear relations of the non-polar gases when expressed in terms of the mol. vol. appear to be proportional to the dipole moment. R. F. D.

Thermodynamic properties from P-V-T data. Robert York, Jr. *Ind. Eng. Chem.* **32**, 54–6(1940).—A method of residuals is proposed which is especially useful for evaluating isothermal changes in thermodynamic properties from P-V-T data. In this advantage is taken of the fact that, along the isometric of the gas, approx. a linear relation exists between pressure and temp. This technique may be applied to evaluate isothermal changes in internal energy, enthalpy, entropy and free energy. Kenneth H. Slagle

Dissociation treatment of condensing systems. III. Properties of saturated vapors of H_2O, NH_3, CH_3Cl and CO_2. T. P. Tseng, S. K. Feng, C. Cheng and W. Band. *J. Chem. Phys.* **8**, 20–3(1940); cf. *C. A.* **33**, 9068[7].—The dissocn. treatment gives a satisfactory theory of the satd. vapor pressure curves in temp. ranges not too close to the crit. point. Curves are given for PV/NkT and for surface energy for H_2O, NH_3, MeCl and CO_2. There is a discrepancy in the energy curves for H_2O at low values of T/T_c; this may be removed by considering the small size of the clusters involved in the equil. between vapor and liquid (the surface energy in a cluster may differ from that for the liquid in bulk). A method of estg. mean cluster size leads to reasonable results. G. M. Petty

Volatility of technical p-nitroaniline with water vapors. A. V. Lebedev. *Khlopchato-Bumazhnaya Prom.* **1938**, No. 10, 33–5; *Khim. Referat. Zhur.* **2**, No. 4, 124(1939).—When diazo solns. are obtained from treatment of tech. p-nitroaniline (I) with hot water, vapors of light volatile substance (o-nitroaniline (II) and p-nitrochlorobenzene) and of water are given off. Lab. expts. (adsorption of the evolved vapors by a 0.5% soln. of H_2SO_4 after collecting them with an aspirator from above the vessel in which the diazo reaction has taken place) showed that the mixing, dissolving and diazotization of tech. I is accompanied by an evolution of nitro compds. (when mixing 0.17–0.25 g., dissolving 0.062 g. and diazotizing 0.055 g. per 38 g. of nitroaniline), whereas no volatile products are evolved from the purified nitroaniline (purified by a 4-fold treatment with hot water followed by filtration) under similar expti. conditions. It was shown (by prepg. mixts. of the purified I with II) that the volatility of the tech. solns. of I is caused by the presence of impurities of II.
W. R. Henn

Determination of the vapor pressure of aluminum chloride and its melts with sodium chloride at high temperatures. I. I. Naryshkin. *J. Phys. Chem.* (U. S. S. R.) **13**, 690–2(1939).—The values of A and B in the equation, $\log p = -(A/T) + B$, for $AlCl_3$-NaCl melts at 150–560° are: 100% $AlCl_3$, 4873, 13.602; 65.5%, 2004, 6.321; 59.4%, 2284, 5.416; and 51.8%, 4673, 7.181, resp. F. H. Rathmann

Density of molten antimony trichloride. D. I. Zhuravlev. *J. Phys. Chem.* (U. S. S. R.) **13**, 684–6(1939).—The d. of $SbCl_3$ is given by $d = 2.622 - 0.002268(t - 100) - 0.32 \times 10^{-5}(t - 100)^2 + 8.8 \times 10^{-12}(t - 100)^4 - 3.4 \times 10^{-14}(t - 100)^5$ from 73 to 505°. The vapor ds. in g./cc. are 0.028 at 324°; 0.123, 428°; 0.147, 442°; 0.171, 456.5°; 0.213, 470°. The crit. consts. are $T_k = 523°$; $d_k = 0.814$ g./cc., $p_k = 58.7$ phys. atm. F. H. R.

Determination of the surface tension by the Jaeger method when the specific gravity of the investigated liquid is not known. S. D. Gromakov. *J. Phys. Chem.* (U. S. S. R.) **13**, 551(1939); cf. *C. A.* **12**, 875.—The equation $P_1 = (2\sigma/r) + h_1 g[(P_2 - P_1)/(h_2 - h_1)]$, most applicable in the region $h_2 - h_1 = 30$–50 mm., is obtained.
F. H. Rathmann

Surface tension of water and heavy water. A. H. Cockett and Allan Ferguson. *Phil. Mag.* **28**, 685–93 (1939).—A micromethod was used to det. the surface tension of H_2O and D_2O in the temp. range 15–75°. For H_2O the values are represented by $\gamma_t = 75.23 - 0.06667t^{1.2}$; for D_2O, $\gamma_t = 74.64 - 0.1082t^{1.1}$. E. J. R.

The surface tension of 100% phosphoric acid and an interpretation of the structure of 100% phosphoric acid. Takesi Takeda. *J. Chem. Soc. Japan* **60**, 885–94(1939); cf. Shibata, *C. A.* **30**, 6667[8].—From the data of viscosity measurement and of Raman spectra, the stereochemistry of 100% phosphoric acid is discussed. T. Katsurai

Effect of carbon dioxide on the surface tension of mercury. R. C. L. Bosworth. *Trans. Faraday Soc.* **35**, 1353–4(1939).—The surface tension of Hg in the presence of air contaminated with various proportions of CO_2 was detd. by the max. bubble method, cf. *C. A.* **33**, 2383[7]. With increasing content of CO_2 the surface tension at first falls to a min. some 8% lower than the value in pure air at 3% CO_2, and thereafter rises very slowly with increasing CO_2 content, the value in pure CO_2 being about 1.5% lower than the value obtained in pure air.
Victor R. Deitz

Surface tensions of two-phase liquid systems containing benzene. J. W. Belton. *Trans. Faraday Soc.* **35**, 1354–61(1939); cf. *C. A.* **30**, 1285[6].—Two systems were investigated at 25°: (1) benzene–CS_2–water and (2) benzene–HOAc–water by a bubble-pressure method (cf. *C. A.* **30**, 669[9]). The adsorptions at the liquid-liquid interfaces were detd. from the Gibbs equation. The adsorption of HOAc at the aq. phase-vapor interface may be detd. by an indirect method; it is almost equal to that at the liquid-liquid interface. Victor R. Deitz

Pressure and temperature effects on the viscosity of liquids. David Frisch, Henry Eyring and John F. Kincaid. *J. Applied Phys.* **11**, 75–80(1940).—The free energy of activation for viscous flow is related to an entropy and energy of activation by the same equations as any equil. and is perfectly general and independent of the mechanism. The equations are developed for a bimol. flow process in which pairs of mols. lying in adjoining layers roll over each other. At low pressures the heat of activation for viscous flow is about $^1/_3$ the energy of vaporization, but as the pressure is raised it increases rapidly because of the work term PV/n'. Calcns. for n- and iso-C_5H_{12}, Et_2O, C_6H_6, H_2O and Hg over pressures ranging from one to 12,000 kg./sq. cm. and at ordinary temps. are found to agree satisfactorily with expti. values. The effect of pressure on viscosity can be calcd. with reasonable success from thermodynamic data only. S. L. Gerhard

The viscosities of chemically related liquids and their dependence on molecular weight and molecular volume. II. David T. Lewis and A. R. Morgan. *J. Chem. Soc.* **1939**, 1341–5; cf. *C. A.* **32**, 8229[6].—It is suggested that any equation representing the variation of viscosity of liquids must contain fundamental terms representing temp., mol. wt. and mol. vol. An equation is derived: $\log \eta = A(\log M)/T + x \log P + \log y$, in which M is the mol. wt., P the parachor, and A, x and y are consts. This equation holds for chemically related series, the generality being ascribed to similarity of cohesive pressures in such series. The fused salts AgCl, AgBr and AgI show indications of a similar relation, but lack of reliable parachor data prevents definite conclusions being drawn as to the effect of the mol. vol. Kenneth H. Slagle

Purification and criteria of purity for physicochemical organic standards. L. Gillo. *Ann. chim.* **12**, 281–347 (1939).—A crit. expti. study of the literature was made to ascertain the nature of the impurities, and their detn., commonly found in MeOH (I), $CHCl_3$ (II) and C_6H_6 (III), and the methods of purification of I, II and III. The article includes expti. procedures either adapted from

the literature or developed by G. The principal impurity common to I, II and III is H_2O which is usually of the order of 0.001%. After one distn. over Na, the H_2O content of I is 0.003%; after a second distn., 0.00005%. The concn. of CH_2O and Me_2CO is approx. 10^{-4}%. Me_2CO is difficultly removed from I by simple distn., and chem. means must be used. II is difficultly purified because of its instability and sensitivity to light and O. The concn. of $COCl_2$ in II cannot be reduced below 3×10^{-4}%. III can be prepd. anhyd. by distn. A procedure is given for the detn. of thiophene in III that is more sensitive than the colorimetric or chronometric methods. This consists in the combustion of a sample of III in a current of H and in the presence of a hydrogenation catalyst, e. g., Pt; S is converted to H_2S and the latter is detd. by reaction with dimethyl-*p*-phenylenediamine to yield methylene blue. In this manner an H_2S content of 2×10^{-6}% can be detd., corresponding to $10^{-6} - 10^{-5}$% thiophene. 154 references. David E. Adelson

Theory of the Clusius separation. P. Debye. *Ann. Physik* **36**, 284 94(1939).—The theory of the Clusius (*C. A.* **33**, 4748) sepn. as applied to liquids is developed for the case of two plates, where the concn. dependence of the diffusion consts. is neglected as is the temp. dependence of the viscosity. The equil. and the time course of the process are discussed. H. C. Thomas

Determination of the vapor pressure of solid salts. III. Vapor pressure of TlCl, TlBr, TlI, $PbCl_2$, $PbBr_2$, PbI_2, $ZnCl_2$, $ZnBr_2$, ZnI_2, $CdCl_2$, $CdBr_2$ and CdI_2, and their thermodynamic calculations. Kitizo Niwa, Munemitu Sato and Masao Yosiyama. *J. Chem. Soc. Japan* **60**, 918–28 (1939); cf. *C. A.* **33**, 4484[5].—The vapor pressures of these solids were measured and their heats of sublimation and at. energies were calcd. T. Katsurai

Comment on Born's thermodynamics of melting. Lewis Balamuth. *J. Chem. Phys.* **8**, 127 8(1940).—Born's theory (*C. A.* **33**, 8072[2]) ignores the departure of the lattice from long-range order before melting occurs. For this reason, no thermodynamic theory of a lattice under finite strain can be safely extrapolated to the m. p. The data of Siegel and Quimby (*C. A.* **32**, 6140[2]) on the temp. variation of a single Na crystal (90–210°K.) do not support the contentions of either Born or Brillouin (*Phys. Rev.* **54**, 916(1938)). G. M. Petty

Vitrification of water. B. J. Luyet. *Phys. Rev.* **56**, 1244(1939).—A procedure for obtaining amorphous water is described. A cylindrical stream of water flowed vertically. A brass disk, 12 mm. in diam. and 2 mm. thick, cooled in liquid air, was mounted 2 mm. behind the stream, with the plane of the disk parallel to the stream. Another brass disk of the same size, mounted on a rod, similarly cooled, was thrown against the first disk, using the spring of a toy pistol. The water between the disks was a film a few microns thick. Pieces of this film remained dark between crossed Nicol prisms for about 30 sec. As the temp. approached the m. p., crystals large enough to be observed with a microscope were seen. G. M. Petty

Diffusion of various metals in aluminum. A. Beerwald. *Z. Elektrochem.* **45**, 789–95(1939).—The diffusion consts. of Cu, Mg, Mn, Ag, Si and Zn in Al were measured. For D in sq. cm./day, the consts. A and Q of the formula $D = A \exp. (-Q/RT)$ are: Cu, 7250, 32,600; Mg, 10,230, 28,600; Ag, 95,400, 32,600; Zn 1,000,000, 27,800; Si, 77,800, 30,550, resp. No results could be obtained for Mn. Analyses were made spectroscopically. H. C. T.

The thermoelectric force of pure beryllium crystals and its change in the transverse magnetic field. E. Grüneisen and H.-D. Erfling. *Ann. Physik* **36**, 357–67(1939).—The thermoelec. force of hexagonal Be is strongly anisotropic: $e(\|/\perp)_{0°C.} = +13.7\ \mu$ v./deg. The decrease between +20° and −250° was measured for both principle directions against manganin. The change of the thermoelec. force of $Be_\|$ and $Be_\perp$ in a transverse magnetic field was detd. as a function of the field direction, field strength and temp. In all respects the behavior of Be is very similar to that of Bi (*C. A.* **30**, 7931[2]). H. C. Thomas

Photoelastic property of rock-salt crystals. Yōiti Kidani. *Mem. Ryojun Coll. Eng.* **12**, 101–14(1939); cf. *C. A.* **31**, 3844[4]; **33**, 9073[6].—The internal strain in natural and synthetic NaCl crystals, brought about by mech. pressure, is analyzed with monochromatic (5890 A.) polarized light. Standardization is made by means of flint glass, measured up to the load 60 g./sq. mm. yielding a relative coeff. of photoelasticity of 6.2×10^{-6} (g. cm.)$^{-1}$. For the elastic limit for natural and synthetic NaCl, the same value of 18–19 g./sq. mm. was obtained. Compared with the synthetic NaCl, the natural rock salt shows photoelastic properties. The math. side of the theory is extensively treated; a possibility of a quadratic relation for the ionic cryst. state and a linear relation for amorphous matter is described. Frederick C. Nachod

An introduction to crystal chemistry. Charles W. Stillwell. *Rept. New Engl. Assoc. Chem. Teachers* **41**, 79–83(1939).—An outline of the basic principles of crystal chemistry. Leopold Scheflan

Demonstration of the mathematical identity of the equations of Laue and Bragg. A. Cavinato. *Atti accad. Lincei, Classe sci. fis., mat. nat.* **29**, 319–21(1939).—The conditions for pos. interference of the space structure of crystals (Laue's equations) are shown to be mathematically identical to those of Bragg. A. W. Contieri

On phase changes in crystals arising from hindered molecular rotation. John G. Kirkwood. *J. Chem. Phys.* **8**, 205–12(1940).—Math.-theoretical. G. M. Petty

Surface reaction between oxonium ions and mica. R. Stevenson Bradley. *Trans. Faraday Soc.* **35**, 1361–6 (1939).—Sheets of mica, freshly cleaved muscovite, were immersed for short times in solns. of pH between 2.5 and 6 at 25°; they were then quickly withdrawn and plunged into KOH to check the reaction and then washed with distd. water. A drop of dil. NH_4I was allowed to dry slowly on the mica and the crystals formed differed from the oriented tetrahedral crystals found on untreated mica surfaces. A mixture of oriented tetrahedra and unoriented cubes occurs, the proportion of the latter increasing with the time of immersion in the acid soln. Log k, the velocity coeff. of the change, *vs.* the pH is a linear plot. The results are interpreted in terms of surface attack by oxonium ions, the surface concn. of which det. the reaction velocity. Victor R. Deitz

The growth, orientation and preparation of the surface of single crystals of copper. Allan T. Gwathmey and Arthur F. Benton. *J. Phys. Chem.* **44**, 35–42(1940).—A modification of the Bridgman method (*Proc. Am. Acad. Arts Sci.* **60**, 305(1925)) using the Quimby furnace was used for prepg. single crystals of Cu $^5/_8$ in. in diam. and 5 in. long. Identification and orientation of the single crystals was made by the action of various etching reagents and detn. of the reflection patterns. The electrolytic etching method gave a very bright and smooth finish. M. McMahon

Two graphical methods for the determination of the optical value of certain crystal faces. I. The representation of the relations between the position of the axis and the extinction position. H. Tertsch. *Mineralog. petrog. Mitt.* **51**, 163–71(1939).—By means of a Fresnel construction the optical vibration direction in a face of a biaxial mineral is detd. and a nomograph is offered relating the axial angle and extinction position for the 110 and 010 faces of *hornblende*. J. F. Schairer

Mechanism of transformation of face-centered cubic into hexagonal close-packed lattice. Z. Nisiyama. *Science Repts. Tohoku Imp. Univ.*, First Ser., **25**, 79–93 (1936); *Neues Jahrb. Mineral., Geol.* Ref. 1, **1939**, 605; cf. *C. A.* **29**, 2416[4].—The mechanism of the transformation of a cubic face-centered lattice (I) into a lattice with hexagonal close packing (II) as shown by a 70:30 Ni-Co alloy is investigated. It results in (111) and [$\bar{2}$11] of I being parallel with (0001) and [1$\bar{1}$00] of II, resp. C. A. S.

Crystal structure of dipropylmonocyanogold. R. F. Phillips and H. M. Powell. *Proc. Roy. Soc.* (London) **A173**, 147–59(1939).—Dipropylmonocyanogold crystals are in the orthorhombic system $a_0 = 17.06$, $b_0 = 22.36$, $c_0 = 10.0$ A., space group *Pca* with 16 mols. of $AuPr_2CN$

(I) per cell. A true mol. consists of four units of I as shown by a Patterson analysis and a Fourier synthesis on (001), (100) and (010), two of these being nonsym. The mol. has a square structure with each side being

—Au—C≡N—Au— (length 5.18 A.), the Au atoms being at the corners and 2 Pr groups linked to each Au atom. The four covalencies of the Au atom are at right angles to one another and coplanar, bond length about 1.3 A. The general position of overlapping Pr and CN groups is shown, particularly in the centrosym. projection on (001). Intermol. distances are not less than 3.4 A. R. F. D. 1

Lattice defects in silver halide crystals. Frederick Seitz. *Phys. Rev.* **56**, 1063–4(1939); cf. *C. A.* **33**, 2387[6]. —The ratio r of the no. of lattice defect atoms to the no. of normal atoms is $r(AgBr) = 29 \exp. (-5050/T)$; $r(AgCl) = 36 \exp. (-6250/T)$. G. M. Petty 2

A new modification of manganese dioxide. Oskar Glemser. *Ber.* **72B**, 1879–81(1939).—X-ray investigation of MnO_2 shows that there is not only a tetragonal MnO_2 existing in the form of the minerals *pyrolusite* and *polianite*, but a form giving an x-ray diagram that differs from the tetragonal. This can be prepd. in 3 ways: I. $MnSO_4$ is dissolved in H_2O and oxidized with HNO_3 and $(NH_4)_2S_2O_8$. The black product is filtered and washed with hot H_2O and dried at 60° for 2 days. II. A soln. of $MnSO_4$ is oxidized with KNO_3 and $KMnO_4$, a brown ppt. being obtained which is filtered, washed with hot H_2O and dried as above. III. $Ba(MnO_4)_2$ is dissolved in H_2O and H_2SO_4 (24.5%) added drop by drop until there is a slight excess. The $BaSO_4$ is removed by centrifuging and the soln. is evapd. at 45°. The ppt. is washed by decantation until the supernatant liquid is no longer violet-red. The brown powder so obtained is washed with hot H_2O and dried as above. Analysis of these products shows the compn. MnO_2, and x-ray examn. indicates that it is a new allotropic cryst. form of this compd., which G. designates γ-MnO_2. H. Stoertz 3

Crystal structure of cyclohexane at −180°. K. Lonsdale and H. Smith. *Phil. Mag.* **28**, 614–16(1939).—X-ray powder photographs of cyclohexane contained in a cellophane tube at liquid O temp. were obtained with filtered Cu K_α radiation. It is not certain whether this compd. has a low-temp. modification of low symmetry or whether 2 cryst. modifications partially coexist at this temp. E. J. Rosenbaum 4

X-ray measurements on wet insulin crystals. Dorothy Crowfoot and Dennis Riley. *Nature* **144**, 1011–12(1939). —X-ray photographs were made of Zn insulin crystals wet with mother (crystg.) liquor, NaH_2PO_4 soln. and Na citrate soln. The wet-crystal unit cell is a moderately expanded version of that of the air-dried crystals (*C. A.* **32**, 3683[8]): the cell dimensions of the wet and dry hexagonal crystals are, resp., a, 83.0, 74.8 A.; c, 34.0, 30.9 A.; for the rhombohedral true unit cell, a, 49.4, 44.4 A.; α, 114° 16′, 114° 28′. The wet-cell mol. wt. is 52,400; the liquid of crystn. weighs 14,800, which is 28% of the total. Striking differences in the x-ray intensities given by the different crystal structures are correlated with a reorientation of the mols. relative to the crystal axes, which occurs on drying. G. M. Petty 5

The gas mixtures of lower hydrocarbons. V. Adsorption of the gas mixtures. Kōe Uehara. *J. Chem. Soc. Japan* **60**, 1149–58(1939); cf. *C. A.* **30**, 6515[9].—The adsorption of the mixts. $CH_4 + C_2H_6$, $CH_4 + C_4H_8$, CH_4 + butane by active charcoal was studied at the pressure range 0.5–60 mm. The amount adsorbed is proportional to the partial pressure of the components. T. K. 6

Adsorption of acetic acid by mercury. R. C. L. Bosworth. *Trans. Faraday Soc.* **35**, 1349–52(1939).—Changes in the surface tension of Hg by the presence of air contg. AcOH vapor were followed at 20° to 260° by a method previously described (cf. *C. A.* **33**, 2383[7]), a variation of the max.-bubble-pressure method. The surface tension and its temp. coeff. are depressed, the latter reversing its sign over certain ranges of temp. The adsorption is accompanied by an evolution of heat of 6.1 kg.-cal. for close-packed films of 4×10^{14} mols./sq. cm. and rises to 8.3 kg.-cal. as the surface concn. is decreased to 0.25×10^{14} mols./sq. cm. Victor R. Deitz 7

Adsorption phenomena between liquid phases. Analytical study of photographically recorded curves. R. Mérigoux and M. Aubry. *J. chim. phys.* **36**, 221–33 (1939).—The time changes of the interfacial tension of H_2O—vaseline oil and H_2O—CCl_4 activated by oleic acid are studied by means of a du Noüy tensiometer arranged for photographic recording. The curves are analyzed in terms of a theory similar to the Langmuir theory of adsorption of gases on solids. H. C. Thomas 8

Adsorption isotherms for mobile monolayers. William Band. *J. Chem. Phys.* **8**, 178–80(1940).—Math.-theoretical. Some numerical predictions are made. G. M. Petty 9

Supplement to the studies on absorption of gas in the form of bubbles. Yositosi Ōyama and Katumi Iwase. *Sci. Papers Inst. Phys. Chem. Research* (Tokyo) **36**, 371–4 (1939) (in English); cf. *C. A.* **33**, 3239[7].—The earlier study using bubbles of 0.3–1.6 cc. is extended to bubbles of CO_2 and air as large as 6.2 cc. Curves for the absorption of these bubbles, expressed per unit vol. of bubble, in 0.01 and 0.1 *N* caustic soda solns. show a definite min. and max. Absorption does not always increase in proportion to the subdivision of the bubble. E. O. Wiig 10

Wetting characteristics of solid surfaces covered with adsorbed films. F. E. Bartell and Kenneth E. Bristol. *J. Phys. Chem.* **44**, 86–101(1940).—Clean hydrophilic surfaces, such as quartz, pyrex, gypsum and mica, and clean organophilic surfaces, such as galena, cinnabar, sphalerite, Sb metal and stibnite, were treated with H_2O vapor and with org. liquid vapors so as to produce definite and controlled adsorption. Contact angles were measured with different liquids upon such surfaces using the sessile-drop method. The adsorbed films are sufficiently thick to mask the original surface properties. Surface tensions of adsorbed films were calcd. by use of Young's equation, with the assumption that the interfacial tension existing between the liquid drop used and the liquid film under it is the same as the interfacial tension between the two liquids in bulk (such an assumption being questionable). M. McMahon 11

States of monolayers on an aqueous subphase. William D. Harkins and Edward Boyd. *J. Chem. Phys.* **8**, 129–30 (1940); cf. *C. A.* **33**, 3225[1].—Dervichian's interpretations (cf. *C. A.* **33**, 9086[2]) are criticized. G. M. Petty 12

Statistical mechanics of condensation phenomena in mobile monolayers. William Band. *J. Chem. Phys.* **8**, 116–19(1940); cf. *C. A.* **33**, 5249[3], 9068[7].—Math. The dissocn. method is modified to cover the condensation phenomena observed in mobile monolayers. The theory agrees well with the curves of Adam and Jessop (*C. A.* **20**, 1542) for the fatty acids. G. M. Petty 13

New method of spreading monolayers of albumin and lipoid-albumin mixtures. Stina Ställberg and Torsten Teorell. *Trans. Faraday Soc.* **35**, 1413–16(1939).—A 60% aq. soln. of PrOH or iso-PrOH contg. 0.5 *M* AcONa was used as a solvent for both serum albumin and lipoids such as cholesterol and lecithin. The soln. can be heated to boiling without pptg. the protein. Such a soln. can be used for spreading monolayers of albumins, lipoids or mixts. thereof. It has excellent film-spreading properties both at the air/water and benzene/water interfaces. Victor R. Deitz 14

Surface films of heat-denatured serum albumin. Stina Ställberg. *Trans. Faraday Soc.* **35**, 1416–20(1939); cf. preceding abstr.—Surface films formed by "native" and heat-denatured serum albumin were spread from soln. in 60% PrOH contg. 0.5 *M* AcONa on a substrate of pH 7.0 (phosphate) contg. 0.15 *M* NaCl and at 20°. Denaturation was found to be accompanied by a 15% increase in area (0.98 to 1.15 sq. m./mg.), changes in the compressibility (0.016 to 0.027 cm./dyne), rigidity and "gelation-point," but by no significant alteration in the apparent dipole moment at low compression of 650–685 milli-Debye. Victor R. Deitz 15

Impedance of bimolecular films. R. B. Dean, H. J.

Curtis and K. S. Cole. *Science* **91**, 50–1(1940).—The prepn. of a bimol. film of tanned egg albumin with water on both sides is described. Using a film area of 0.07 sq. cm., the series resistance (670–1450 ohms) is plotted against the series reactance (0–250 ohms) for 30–200,000 cycles per sec. The capacitative impedances of the films had const. phase angles of 65–68° and capacities of 1.07–1.23 microfarad/sq. cm. at 1000 cycles/sec. This resistance is in marked contrast to very low resistances found in untanned protein films. Complex lipo-protein films may have an appreciable resistance and be able to produce diffusion potentials in biol. systems. The const. phase angle and a capacity of approx. 1 microfarad/sq. cm. is a characteristic of all living cell membranes. These are the first artificial films produced between two aq. phases with these properties. G. M. Petty

The depolarization of light diffused by several colloidal solutions. A. Boutaric and J. Breton. *J. chim. phys.* **36**, 193–200(1939); cf. *C. A.* **33**, 5289⁹.—The coeffs. of depolarization at 90° to the incident beam were measured for suspensions of gum mastic, sols of As_2S_3 and $Fe(OH)_3$, and suspensions of bentonite and clay. The coeffs. increase with concn. in a different manner for each suspension and for a given concn. depend on the manner of prepn. of the sol and on the time. H. C. Thomas

Magnetooptical and natural dispersions of isobutyl butyrate and ethylene chloride. W. J. G. Beynon. *Phil. Mag.* **28**, 548–61(1939); cf. *C. A.* **32**, 4076⁹.—The magnetooptical dispersion of isobutyl butyrate at 10.4° is $0.005616\ [\lambda^2/(\lambda^2 - 0.1106^2)]^2$ and the natural dispersion is given by $n^2 - 1 = 0.95409 + 0.009642/[\lambda^2 - 0.1106^2]$, with a temp. coeff. of 0.0005. For ethylene chloride at 18.4° the magnetooptical dispersion is $0.007569\ [\lambda^2/(\lambda^2 - 0.1227^2)]^2$ and the natural dispersion is given by $n^2 - 1 = 1.04803 + 0.01255/[\lambda^2 - 0.1227^2]$, with a temp. coeff. of 0.0006. The values of e/m in e. m. u. $\times 10^7$ are 1.018 and 1.028 for isobutyl butyrate and ethylene chloride, resp. Absorption bands in the infrared have no effect on dispersion in the visible or ultraviolet. E. J. R.

The influence of Brownian movement on the viscosity of solutions. R. Simha. *J. Phys. Chem.* **44**, 25–34(1940); cf. *C. A.* **32**, 1542⁴.—The viscosity of dil. solns. of nonspherical particles was calcd. as a function of their dimensions and of the concn. Three different cases were considered, depending on the magnitude of the factor K/D (D = rotational diffusion const. of the particles assumed as spheroids and K = velocity gradient of the flow in the viscosimeter): (1) K/D infinite, from Jeffery's results on the viscosity of a suspension of ellipsoids (*Proc. Roy. Soc.* (London) **A102**, 163(1923)), (2) finite K/D, in which irregular thermal motion is superimposed upon the orientation tendency and (3) $K/D \to 0$, complete Brownian movement, where the macroscopic flow is no longer able to bring about a regular rotational motion of the ellipsoids against the thermal motion, which, on the av., effects an isotropic distribution of the particle axes in the fluid. M. McMahon

The plastic state. Measurement of plasticity. Paul Bary. *Rev. gén. caoutchouc* **16**, 260–3(1939).—A crit. review of the physics and chemistry of the plastic state, in which important contributions by various investigators are discussed, leads to certain novel points of view. The various definitions of plasticity fail in that they are not in accord with the fact that plasticity is a function of temp. It is inappreciable below a definite temp. range, increases to a max. at a higher temp. and diminishes again to zero at an elevated temp. The fluidity μ can be calcd. by the equation: $\mu = (S.\Delta L)/(LFt)$, where S is the cross-sectional area of the test-specimen, L its length and F the stress to give an elongation ΔL in time t. The rigidity R within the plasticity range is the rigidity of the reticular and colloidal parts of the substance, and it can be estd. by the relation: $R = F/S$, where F is the min. stress to produce transverse shearing in a test-specimen of rectangular cross-section S. The plasticity P can then be defined by the product of the fluidity and the resistance to shearing, i. e., $P = \mu R$. These relations are very evident in a graph, with the abscissa representing temps. between the 2 transformation points, and the ordinate representing the fluidity on 1 scale and the resistance to shearing on a 2nd scale. The plasticity, as product of these 2 factors, is also represented by a curve with zero points at 2 end temps. and with an intermediate max. At this max. point, the substance is in the best state to be deformed by molding under pressure, with retention at this temp. of sufficient mech. strength so that it can be removed from the mold without having to be cooled. In general it is shown that plasticity can be defined on a phys. basis and can be measured at any temp. 18 references. C. C. Davis

Colloidal behavior of clays as related to their crystal structure. T. F. Ford, A. G. Loomis and J. F. Fidiam. *J. Phys. Chem.* **44**, 1–12(1940).—Detailed expts. with Na tannate, Na hexametaphosphate, Na pyrophosphate, Na silicate and clay suspensions confirm Garrison's view (*C. A.* **33**, 4849¹) that small amts. of these chemicals are adsorbed on sp. portions of the exterior of clay particles and reduce the viscosity of concd. suspensions by destroying the aggregation of the clay particles into structures. Curves show the amts. of salts required to produce gelation; they appear to be independent of the amt. of clay in a given amt. of H_2O. The effectiveness of the salts in both gelation and coagulation of clay suspensions increases decidedly with the valence of the pos. ion. Crystal structures of clays permit deriving chem. formulas for colloidal clay particles. The dual action of NaOH on suspensions is considered. M. McMahon

Effect of "T" and "R" activation on gold colloids. Giorgio Piccardi and Edmondo Botti. *Gazz. chim. ital.* **69**, 609–14(1939); cf. P., *Atti. accad. Lincei, Classe sci. fis., mat. nat.* **29**, 84(1939).—Aq. Au colloids were prepd. with highly purified reagents from normal and activated multidistd. water, and the differences in the colloidal suspensions with the 2 types of water were noted. With normal water, and relatively small proportions of Na_2CO_3, the color was bright-red, transparent and with a slight yellowish turbidity by reflected light. With increase in Na_2CO_3 the color passed to violet, dark-blue, light-blue and gray-blue or pale-lilac, with final pptn. of black Au. Neither with T-activated nor R-activated water were the times for the appearance of the colors significantly different from the times with the colloids prepd. from normal water. But the colors with both activated waters were displaced toward the blue in relation to those with normal water under the same conditions, e. g., under the conditions of time, temp. and concn. at which bright reds and violet-reds are evident with normal water, the colors were violet-red and violet, resp., with T-activated water, and violet and dark blue, resp., for R-activated colloids. The displacement was therefore even greater for the R-activated colloids than for the T-activated colloids. Also the colors tended to be more intense for both activated colloids. The bluer colors of the activated colloids indicate that their particles were larger than those in the normal colloids but more homogeneous. This was confirmed by reflected light, whereby the activated colloids showed a yellowish turbidity but clearer than the corresponding colloids in normal water. In the case of a normal and activated colloid of the same color, differences were still evident in the turbidity. The differences in colloids activated by T and R activations are quant. rather than qual., at least in appearance. Hence in the case of Au colloids, T and R activations seem to act in the same way rather than in opposite ways. Although the reason for this is not clear, it is of particular significance, since T and R activations have opposite effects on other colloids, such as As_2S_3 and $Fe(OH)_3$ (cf. P., *C. A.* **32**, 8859⁶). C. C. Davis

Chemical preparation of colloidal suspensions in nonaqueous solvents. I. Methyl alcohol and benzene. Arthur A. Vernon and Harrison A. Nelson. *J. Phys. Chem.* **44**, 12–20(1940).—The methods of Gorbowski (*Ber.* **36**, 125(1903)) and Gutbier (*Z. anorg. Chem.* **31**, 448; **32**, 348(1902)) for the prepn. of metal organosols with org. solvents were tried. With hydrazine hydrate, P, P-hydrazine, tannin, $SnCl_2$ and H as reducing agents, stable metallic organosols were prepd. in MeOH and benzene. Collodion (cellulose nitrate in amts. of 0.2% or

more) was a good protective agent with alc. suspensions; with benzene suspensions rubber was generally the protective agent used. Colloidal suspensions of metallic sulfides were pptd. in the same dispersion media by passing dry H_2S through dil. solns. of metallic salts. The more important sols studied are Au, Ag, Pb, Bi, Sb, Ni, Cu, Co, Cr. II. **Ether, 1,4-dioxane and acetone.** *Ibid.* 21–5. —The use of various reducing agents and of H_2S was found to apply equally well with ether, dioxane and acetone as solvents. The protective agents used were collodion for acetone and dioxane and rubber for ether. A comparison with results in Part I shows that the suspensions decrease in stability in the order: alc., dioxane, benzene, ether, acetone. M. McMahon

Influence of sol concentration on flocculation values. E. D. Fisher and C. H. Sorum. *J. Phys. Chem.* **44**, 62–70 (1940).—The flocculation values of pure hydrosols of Cr$(OH)_3$, Fe_2O_3, As_2S_3, MnO_2, SnO_2, $Al(OH)_3$, TiO_2 and $Th(OH)_4$ for the various coagulation ions show that the pure sols follow the rule of Burton and Bishop (*C. A.* **15**, 969) when coagulated by ions of varying valences; values increased for univalent ions, remained the same for bivalent ions, and decreased with multivalent ions. When sols were made impure with stabilizing electrolyte the behavior was contrary to the rule—flocculation values for all electrolytes decreased. Diln. with dehydrating agents (such as alcs.) produces a decrease in flocculation values attributable to the dehydrating nature of the dilg. liquids. M. McMahon

Phase-rule behavior of concentrated aqueous systems of a typical colloidal electrolyte—sodium oleate. Robert D. Vold. *J. Phys. Chem.* **43**, 1213–31(1939).—A preliminary report on the phase-rule behavior of Na oleate and water is presented. Visual observation of the temps. of phase change, dilatometric expts., isothermal vapor pressure detns., phase sepns., and microscopic examn. between crossed Nicols are some of the methods used in this investigation. Data and photomicrographs of various phases are presented. It is found that there are many more phases than had previously been recognized in systems of soap and water. All the equil. are successfully represented on a phase-rule diagram in which the independent variables are temp. and compn. L. Kolodny

Silicic acid gels. IX. Effect of a change of pH on the time of set of some acid gels. Charles B. Hurd and Harris W. Paton. *J. Phys. Chem.* **44**, 57–62(1940); cf. *C. A.* **32**, 2003⁷. The time of set of silicic acid gels, prepd. from solns. of Na silicate and AcOH, may be increased by addn. of more H_2O or more AcOH soln. Data show a quant., straight-line relation between the time of set of the mixt. and the time elapsed from the time of mixing the original soln. to the time of addn. of extra acid or H_2O. There is apparently no especially significant point in the setting process at which addn. of more acid has a particularly marked effect. The fibrillar condensation theory of silicic acid gel structure is discussed in view of these results. M. McMahon

A note on the diffraction of x-rays by vitrified and by frozen gelatin gels. W. H. Barnes and F. W. Matthews. *Biodynamica* No. **49**, 1–7(1939).—The observations of Luyet on the vitrification of gelatin gels (*C. A.* **32**, 3685⁷) are confirmed by x-ray examn. J. McAfee

Determination of the vapor pressure of solutions. II. Vapor pressure of deuterium oxide solution of potassium chloride. Kitizo Niwa and Eiiti Simazaki. *J. Chem. Soc. Japan* **60**, 985–94(1939); cf. *C. A.* **28**, 396⁶.—The vapor pressures of D_2O and of KCl solns., 0.1732 *M* to satn., were detd. at 4 to 13°. From various physicochem. data, such as heat of vaporization of deuterium oxide, the heats of sublimation and melting of heavy ice are estd. T. Katsurai

Viscosity of mixtures of ammonia and water at 20°. V. A. Pleskov and I. Igamberdyev. *J. Phys. Chem.* (U. S. S. R.) **13**, 701–2(1939).—A few values for the viscosities of liquid NH_3-H_2O mixts. at 20° are: 0% H_2O, 0.00146; 31.7, 0.00503; 61.86, 0.01249; 71.23, 0.01303; 80.2, 0.01267; 100, 0.01009. The max. at 71–2% H_2O corresponds to $NH_3.xH_2O$ (x = 2 or 3). F. H. R.

Viscosity of aqueous solutions of formic, cyanoacetic and oxalic acids. M. K. Srinivasan and B. Prasad. *J. Indian Chem. Soc.* **16**, 371–4(1939).—The viscosities of formic, cyanoacetic and oxalic acids were measured at 35°. The viscosity of these solns. is well represented by either of 2 equations, viz. (1) $(\eta - \eta_0)/\eta_0 = A\sqrt{\alpha c} + \beta(1 - \alpha)c$, connecting viscosity, concn. (c) and the degree of dissocn. (α) of an aq. soln. of a weak electrolyte, on the assumption that the increase in relative viscosity $(\eta - \eta_0)/\eta_0$ of such a soln. is due to 2 additive factors, *viz.* (a) $\Delta_1/\eta_0 = A\sqrt{\alpha c} + B\alpha c$, and (b) $\Delta_2/\eta_0 = \beta(1 - \alpha)c$, and (2) $(\eta - \eta_0)/\eta_0 = A\sqrt{\alpha c} + B\alpha c + \beta(1 - \alpha)c$. But the values of the viscosity consts. are not of the expected order. The results are also represented by the Jones and Dole equation, but the consts. have no theoretical significance for weak electrolytes. A. H. Krappe

Investigation of the electroconductivity of molten carnallite. A. A. Shcherbakov and B. F. Markov. *J. Phys. Chem.* (U. S. S. R.) **13**, 621–30(1939).—With an app. giving measurements to within ±0.4%, the electroconductivities of the systems KCl-NaCl (I), NaCl-$MgCl_2$ (II), KCl-$MgCl_2$ (III) and KCl-NaCl-$MgCl_2$ (IV) at temps. from 660 to 880° are detd. The conductivities are almost linear functions of temp. The isotherms for the systems I and II are smooth curves without particular points, III has two inflection points and a const. cond. region from 40 to 80 mol. % $MgCl_2$. F. H. Rathmann

Thermodynamic properties of solutions of amino acids and related substances. IV. Effect of increasing dipolar distance on the activities of aliphatic amino acids in aqueous solution at 25°. Elizabeth R. B. Smith and Paul K. Smith. *J. Biol. Chem.* **132**, 47–56(1940); cf. *C. A.* **32**, 3239⁶.—The osmotic and activity coeffs. of β-alanine, *dl*-β-aminobutyric acid, γ-aminobutyric acid, *dl*-β-aminovaleric acid, *dl*-γ-aminovaleric acid, and ε-aminocaproic acid were calcd. from isopiestic vapor-pressure measurements made in aq. soln. at 25°. The larger the dipole moment the lower the osmotic coeff., this effect being opposite to that of increasing the length of the C chain. Relations between the activity coeffs. and the dielec. consts. of the solns. are discussed. V. **Activities of some hydroxy- and *N*-methylamino acids and proline in aqueous solution at 25°.** Paul K. Smith and Elizabeth R. B. Smith. *Ibid.* 57–64.—The osmotic and activity coeffs. of *dl*-proline, *l*-hydroxyproline, *dl*-serine, *dl*-threonine, sarcosine, and betaine were calcd. from isopiestic vapor-pressure measurements made in aq. soln. at 25°. The strongly polar OH group in the hydrocarbon chain depresses the osmotic coeff. Amino acids with *N*-Me groups (sarcosine, betaine) have higher osmotic coeffs. than their straight-chain analogs (alanine, α-aminovaleric acid). Relations between the activity coeffs. and dielec. consts. of the solns. are discussed. D. S. Searle

Thermodynamics of acid-base equilibria. D. H. Everett and W. F. K. Wynne-Jones. *Trans. Faraday Soc.* **35**, 1380–1401(1939).—Theoretical. Analysis of the available exptl. data for the electrolytic dissocn. of some weak acids leads to values of $\Delta G°$, ΔH, $\Delta S°$ and ΔC_p for the 49 various equil. For a complete comparative study of the strengths of acids, the values of all the thermodynamic functions must be considered along with the dissocn. const. For ionization processes of uncharged acids at room temps., the heat-capacity change is always neg. and large and the entropy change is also usually neg. The thermodynamically derivable equation, $\ln K = A/T + (\Delta C_p/R)\ln T + B$, is used in this analysis. Simple electrostatic considerations based on Born's equation do not give values large enough to account for the whole of the heat-capacity change envolved in the equil.; orientation effects account for the remainder. Victor R. Deitz

Ionic equilibria in acid salts of dibasic acids. Cecil W. Davies. *J. Chem. Soc.* **1939**, 1850–3.—In a soln. of an acid salt of a weak dibasic acid in water 2 successive reactions occur: (1) $NaHA \rightarrow Na^+ + HA^-$ and (2) $HA^- + HA^- \rightleftharpoons H_2A + A^{--}$. Acid dissocn. of HA^- is usually unimportant compared with (2). The relative amts. of H_2A, HA^- and A^{--} are independent of the concn. and may be calcd. if the 2 dissocn. consts. of the acid are known.

As much as 25% of the acid radical may be present as H_2A and the same amt. as A^{--}. Because of the high concn. of A^{--} the ionic strength may reach 125% of the molar concn. of the salt. *Buffers* contg. polybasic acids should not be used in conjunction with solns. contg. multivalent cations. Calcns. of the *mobility* of the intermediate ion HA^- from cond. measurements give for Na H malonate, Na H succinate and Na H glutarate $\Lambda_0 HA^-$ values equal to 38.0, 35.8 and 29.7, resp. W. B. K.

Dissociation constant of β-resorcylic acid. C. T. Abichandani and S. K. K. Jatkar. *J. Indian Chem. Soc.* **16**, 385–8(1939).—The dissocn. const. K_1^a of β-resorcylic acid was detd. by the measurement of the e. m. f. of the cell without liquid junction: H_2|HA, NaA, NaCl|AgCl-Ag. The corrected value of K_1^a in pure H_2O was found to be 6.05×10^{-4} at 30°. A. H. Krappe

Hydrogen-ion concentration of solutions containing zinc hydroxide and sodium hydroxide. S. M. Mehta and M. B. Kabadi. *J. Indian Chem. Soc.* **16**, 379–84(1939); cf. *C. A.* **33**, 8087[6].—The H-ion concn. of solns. contg. ZnO and Na_2O in varying proportions was detd. by means of a glass electrode. The results obtained previously were confirmed. It is inferred that in solns. more dil. than 6 *N* the Na zincate is largely hydrolyzed, whereas in concd. solns. the hydrolysis is small. The possibility of isolating Na zincate from solns. stronger than 8 *N* is suggested. A. H. Krappe

Potentiometric method for the accurate measurement of hydrogen-ion activity. Walter J. Hamer and S. F. Acree. *J. Research Natl. Bur. Standards* **23**, 647–62 (1939)(Research Paper No. 1261).—A detailed description is given of the equipment and exptl. procedure for the precise detn. of H-ion activity by means of a cell without liquid junction; thus Pt|H_2(g)|soln. NaCl (or KCl)|AgCl|Ag. The electrodes function reversibly and exhibit no aging, hysteresis or polarization effects. The e. m. f. of the cell is reproducible to 0.02 mv., which is equiv. to 0.0003 pH unit. The method is applied to the detn. of pH values in mixts. of Na malonate and Na acid malonate. S. Glasstone

Quasi-reversible conduction and galvanic cells with liquid-liquid junctions. F. O. Koenig. *J. Phys. Chem.* **44**, 101–35(1940).—Four defects in the existing thermodynamic theory of cells with liquid-liquid junctions are considered with the object of (a) showing that it is possible to neglect the effects of diffusion in a less artificial manner than in the existing theory, (b) extending the definition of transport no. to include solns. subject to diffusion and thereby clarify relations between migration expts. and cells with liquid-liquid junctions, (c) discovering what thermodynamic laws hold if the restriction to cylindrical symmetry is abandoned, and (d) prepg. the way for a unified theory of cells with liquid-liquid junctions and gravity cells. Assumptions and definitions lead to a theorem which is called the condition for quasi-reversible conduction, or the *qrc* condition. By use of this *qrc* condition the thermodynamic laws of cells with liquid-liquid junctions are deduced. M. McMahon

Use of zeolitic membrane electrodes. C. E. Marshall. *J. Phys. Chem.* **43**, 1155–64(1939).—Exptl. data on the use of zeolitic membrane electrodes to measure cationic activity are presented and discussed theoretically. Details of the prepn. of electrodes, app., and technique are described. Chabazite and apophyllite crystals are the zeolitic membrane materials used. Measurements are made using both uni- and bivalent cations. Exploratory in nature, this investigation suggests the possibility of using zeolitic membrane electrodes for measuring cation activity in colloidal systems. L. Kolodny

Surface structure of passive iron. P. D. Dankov and N. A. Shishakov. *Compt. rend. acad. sci. U. R. S. S.* **24**, 553–5(1939)(in English); cf. *C. A.* **33**, 6214[5].—Electronograms of passive Fe films (prepd. by condensing Fe vapor on mica or glass in vacuo, exposing to air, then submerging immediately in satd. aq. $K_2Cr_2O_7$, 0.05 *N* aq. K_2CrO_4 or strong HNO_3, washing the sepd. films with H_2O and drying) indicate (1) the presence of a thin layer of extremely small crystals of cubic Fe_3O_3 (γ-Fe_2O_3) having the oxide lattice const., *a*, equal to 8.29 ± 0.05 A., and (2) that the Fe lattice is approx. 1.5% greater than that of α-iron (shown by comparison of Fe lines with kaolin lines). The above data do not agree with the work of Finch (*C. A.* **33**, 4100[5]) unless a possible amorphous oxide component is assumed to be present in the film. George Ayers

Constants of gas reaction balance. D. A. Chernobaev and A. G. Zhivotovs'kiĭ. *Akad. Nauk. U. R. S. R., Inst. Khem. Tekhnol.* (Kiev) 1939, 90 pp.(English summary); cf. *C. A.* **29**, 3900[4]; **31**, 2078[4].—The equil. consts. of gas reactions are calcd. by precise and approx. methods, and accompanied by a series of tables. The most accurate results are obtained by spectroscopic methods, but calorimetric methods have attained a high degree of accuracy. A method is described for calcg. the equil const. for gases at high pressures based on the works of Newton and Dodge (cf. *C. A.* **29**, 3900[8]). Tables give a collection of data from the latest spectroscopic investigations, or, where these are lacking, other exptl. data. For the reactions of burning fuel, available spectroscopic data permit precise detn. of the const. By using the tables of free-energy values, log K_p for every 100° and in many instances for every 50°, up to 1500°K. can be detd. from the tables, and for higher temps. up to 3000° by interpolating: $\log K_p = (A/T) + B \log T + C$. A number of formulas are given for the reactions of the most important gases, and compds. of N, S, Cl and Br, and with an abs. error of not more than 0.001–0.002. B. Gutoff

The reaction of aluminum with siliceous slags. Friedrick Weibke and Erich Frey. *Z. Elektrochem.* **45**, 807–12 (1939).—The equil. of the reaction $4Al + 3SiO_2 \rightleftarrows 3Si + 2Al_2O_3$ was investigated in melts contg. Na_2O. The effects of time and of the various concn. factors are detd. The results are summarized in the form of an "equil. const." for the reaction. The const. does not depend on the Na_2O content. H. C. Thomas

Kinetics of phase change. II. Transformation-time relations for random distribution of nuclei. Melvin Avrami. *J. Chem. Phys.* **8**, 212–24(1940); cf. *C. A.* **34**, 1233[1].—Math.-theoretical. G. M. Petty

Hidden periods of crystallization and the equation for the velocity of formation of crystal nuclei. M. L. Chepelevetskiĭ. *J. Phys. Chem.* (U. S. S. R.) **13**, 561–71 (1939).—Exptl. data are given on the hidden periods of crystn. of several salts as a function of supersatn. and temp. The hidden period is a criterion of the rate of formation of nuclei and their growth. The equation for the rate of growth of crystal nuclei is analogous to that for the condensation of a liquid from a vapor with the addn. of a viscosity factor. From these data the approx. sp. surface energies of crystals on the boundary solid body-liquid are calcd. to be $A(M/\rho)\delta \times 12$; $Ca(H_2PO_4)_2.H_2O$, 2.4; $CaSO_4.2H_2O$, 7.2; $CaCO_3$, 60; $CaSO_4$, 65; $FePO_4.2H_2O$, 95; $BaSO_4$, 101; and CaF_2, 132, in good agreement with calcns. from hardness data according to Hertz, Auerbach and Fersman. F. H. Rathmann

The kinetics of thermodiffusion in liquids. K. Wirtz. *Ann. Physik* **36**, 295–302(1939).—See *C. A.* **33**, 9093[7]. H. C. Thomas

Growth of crystals from a stream of vapor. R. N. Haward. *Trans. Faraday Soc.* **35**, 1401–13(1939).—The rate of growth of a crystal mass from a vapor stream of known d. was detd. In no case is the condensation coeff. of const. magnitude. For salicylic acid (+24° to −40°) at stream ds. of 0.071 to 4.0 mg./min. on the surface area of the target used, the ratio of mols. leaving the furnace to those striking the target was a const. equal to 0.234; the rate of evapn. at +7° was 0.092 mg./min. The expts. are explained by a bimol. process occurring in a mobile surface phase and this is in agreement with the crystal structure. Results are given also for I at −44.4°, −46.8° and −52.6°; SnI_4 at 7°; anthracene and HgI_2 at 22.9 and 13.6°. Victor R. Deitz

Reaction velocities at low temperatures. I. A convenient low-temperature thermostat. R. P. Bell and J. K. Thomas. *J. Chem. Soc.* 1939, 1573–5.—A simple low-temp. thermostat is described which depends for its

cooling on the evapn. of a liquefied gas from an annular space around a vessel contained in a large Dewar flask. II. **The bromination of acetone between −40 and +10°.** *Ibid.* 1575–8.—At low temps. in solvents high in acetone the reaction between I and acetone does not go to completion. With Br the reaction is complete in 90.9% acetone and nearly so in 95% acetone. The bromination was studied with HCl (−40° to +10°) and with HBr (−20 to 0°) as catalysts. The Arrhenius equation is obeyed within the limits of exptl. error and the activation energy (19,900 cal.) is substantially the same as for H^+-ion catalysis in aq. soln. H. C. Thomas

The rate of dissociation of pentaarylethanes. W. E. Bachmann and Gerald Osborn. *J. Org. Chem.* 5, 29–39 (1940).—Pentaarylethanes (I) undergo reversible dissocn. into free radicals and if the rate of reaction with O is actually a measure of the rate of dissocn., the same rate should be found with other reagents capable of reacting rapidly with the radicals. It is found that a soln. of I in a mixt. of EtOH and pyridine (cf. Ziegler, Ewald and Orth, *C. A.* 24, 3773) readily reacts at 70–100° with the radicals with practically the theoretical amt. of I, forming triphenylmethyl ethyl ether and diarylmethylpyridinium iodides. Satisfactory solvents are *o*-$C_6H_4Cl_2$, PhBr, $C_6H_4Me_2$ and α-bromonaphthalene. In the method used a weighed sample of I is added to a measured vol. of I soln., the mixt. kept in a const.-temp. bath for a definite time, then removed quickly and chilled. An excess of standard $Na_2S_2O_3$ soln. is added and the excess titrated with a standard I soln. The rate of dissocn. of the following $Ph_3CCHPhR$ derivs. is measured at 80°: with R = Ph, *p*-C_6H_4Me, *p*-C_6H_4OMe, *p*-biphenyl, 2-fluoryl (II), α-naphthyl, and 9-phenanthryl (III). II is prepd. by coupling 2.79 g. Ph_3CNa with 2.91 g. phenyl-2-fluorylchloromethane ording to B. (*C. A.* 32, 7447[1]) in 49% yield. II m. 152–62° in air and 164–8° in N to an orange colored liquid. For the prepn. of III, *phenyl-9-phenanthrylchloromethane* (IV), m. 114–16°, is prepd. by satg. a cold soln. of 8.52 g. phenyl-9-phenanthrylcarbinol (V) in 70 cc. dry C_6H_6 contg. 3 g. $CaCl_2$ with HCl. The *bromo deriv.* of IV, obtained in 95% yield from V and AcBr, m. 115–16°. When 3.03 g. IV in 5 cc. C_6H_6 is allowed to react with an ice-cold soln. of Ph_3CNa, III is obtained in 80% yield. III m. 176–88° in air and 190–3° in N to a reddish orange liquid. The results show that the 9-phenanthryl, α-naphthyl and 2-fluoryl groups are most effective in promoting a rapid dissocn., the *p*-biphenyl and the *p*-C_6H_4OMe groups have an intermediate effect, while the *p*-C_6H_4Me and the Ph groups are least effective. The energies of activation for the dissocn. of pentaphenylethane and of III are detd. F. E. Brauns

Conversion of chlorophyll to pheophytin. G. Mackinney and M. A. Joslyn. *J. Am. Chem. Soc.* 62, 231–2 (1940); cf. *C. A.* 32, 4863[9].—For the pure *a*- and *b*-chlorophyll components, it is confirmed that the reaction involving loss of Mg is of 1st order with respect to acid. It is probably of the same order with respect to chlorophyll. The 2 H atoms replacing the Mg atom must therefore enter at different rates and in all probability the entrance of the 1st H is the rate-governing step. This would materially weaken the remaining Mg-N bond, in which respect it would then no longer be equiv. to the initial condition, presumably highly covalent in character. Chlorophyll *a* reacts from 7 to 9 times as rapidly as chlorophyll *b*. C. J. West

The absolute rates of heterogeneous reactions. II. Electrode reactions. George E. Kimball. *J. Chem. Phys.* 8, 199–204(1940); cf. *C. A.* 32, 7331[8].—The theory is extended to include reactions at electrode surfaces. The resulting expression for the rate of an electrode reaction includes both activation-controlled and diffusion-controlled reactions. The problem of the effect of stirring rate on reaction rate is discussed. The results are applied to the theory of reactions at "floating" electrodes, e. g., the soln. of metals in acids. The reaction rate expressions at such electrodes are of a very complex form, but can be approximated in special cases. The rate of such a reaction depends in general not only on the concn. of the principal reactants, but also on the concn. of every ion in the soln. G. M. Petty

Reactions in a medium of concentrated sulfuric acid. XVIII. The oxidation of artificial sulfides. Jaroslav Milbauer, J. Kurka and J. Mikolášek. *Chem. Obzor* 14, 193–5(1939).—In the oxidation of H_2S by H_2SO_4 contg. S the reaction $S + 2H_2SO_4 \rightleftharpoons 3SO_2 + 2H_2O$ proceeded irregularly because the S liberated from the catalysts formed in drops of an unequal size and in irregular dispersions. When the quantity of the catalyst remained at a 0.0001 *M* equiv. of the acid the oxidation of S began in the nascent state and proceeded almost linearly to a max. value. The time in mins. required to reach this max. was for the following sources of S: Ag_2S 20, As_2S_3 25, ZnS 25, Sb_2S_3 35, FeS 35 and HgS 75. In the presence of $HgSO_4$ this time of oxidation was Ag_2S 35, FeS 35, Sb_2S_3 45, ZnS 50, As_2S_3 65 and HgS 90. In the presence of SeO_2 the time of oxidation was Ag_2S 20, ZnS 20, HgS 30, FeS 33, Sb_2S_3 45 and As_2S_3 55. Both H_2SO_4 and SeO_2 increased the completeness of the reaction from 1 to 17%. **XIX. Notes on ethylene.** *Ibid.* 213–15.—Ethylene passed through H_2SO_4 becomes dark. This darkening, dependent upon partial pressures, was slow at room temps. but became faster at 200°; the small increase in the reaction velocity was due to the decrease in the absorption of C_2H_4 at elevated temps. $HgSO_4$ catalyzed the reaction producing the darkening; $(NH_4)_2SO_4$ retarded the reaction. During the reaction SeO_2 was reduced to free Se, the reaction being influenced by the equil. mass of SeO_2 and Se. The catalyst V_2O_5 was reduced, leaving a green soln. which retarded the darkening. At room temps. traces of SO_2 appeared when the C_2H_4 passed through H_2SO_4 contg. $HgSO_4$; at 200° the quantities of SO_2 appearing were large. The decompn. of C_2H_4 in H_2SO_4 contg. the catalyst $HgSO_4$ was slower than the decompn. of C_2H_2 by H_2SO_4 without any catalyst; the presence of H retarded the decompn. of both C_2H_4 and C_2H_2. **XX. The combustion of some sulfide minerals.** *Ibid.* 215–19.—The rate of the evolution of SO_2 from 50 cc. of 98.7% H_2SO_4 ventilated by 0.5 l. of N per hr. in the presence of 0.05–0.15 mol. of the mineral ore with or without the addn. of $HgSO_4$ or SeO_2 was detd. at 302°. Sphalerite was oxidized faster than artificially prepd. ZnS; the oxidation was 78.2% complete, was not influenced by $HgSO_4$, and was hastened by SeO_2. The oxidation of auripigment occurred at the same rate as the oxidation of pptd. As_2S_3; it was 72% complete, hastened by SeO_2 and not influenced by $HgSO_4$. The oxidation of antimonite was faster and more complete than the oxidation of pptd. Sb_2S_3; it was 42% complete, not influenced by $HgSO_4$ and hastened by SeO_2. The oxidation of cinnabarite was slower than the oxidation of pptd. HgS; it was 99.1% complete, hastened by SeO_2 and not influenced by $HgSO_4$. The oxidation of marcasite was faster and more complete (82.9%) than that of pyrites. The oxidation of these minerals in H_2SO_4 was identical to their behavior in concd. HNO_3. Frank Maresh

A new procedure for calculating combustion temperatures and its application to mixtures of alcohol vapor, water vapor and oxygen. H. Zeise. *Z. Elektrochem.* 45, 893(1939); cf. *C. A.* 33, 6698[4].—Corrections to Table 3 of the previous paper; the general conclusions remain unchanged. S. Glasstone

Kinetic study of combustion in mixtures of hydrogen, carbon monoxide and oxygen. M. Prettre. *Mém. poudres* 29, 283–325(1939).—Combustion is regulated by the O and H, the O and H having 2 mechanisms of combustion according to the sum of their partial pressures. The presence of KCl causes a lessening in the speed of oxidation in cases where the percentage of O is low. Cf. *C. A.* 27, 4083. A. J. Phillips

Effect of variation of piston surface on rate of compression of the crushers. Application to law of combustion of colloidal powders. H. Muraour and G. Aunis. *Mém. poudres* 29, 216–21(1939).—The combustion law may be put in the form $V = a + bP$, where *a* is negligible under high pressures. If the speed of combustion is proportional to the pressure, the rate of compression of the crusher, at a given interval, should be independant of the piston sur-

face. This theory was confirmed, for high pressures where a is negligible, by tests on tubular powders with pistons of ½, 1, 2, 3 and 4 sq. cm. When a is appreciable, the rate of crushing increases as the piston surface increases.
A. J. Phillips

The kinetics of exchange reactions. II. Propyl, isopropyl and isobutyl bromides. G. A. Elliott and S. Sugden. *J. Chem. Soc.* **1939**, 1836–8; cf. *C. A.* **33**, 9128[1].—By using Rd-Br as an indicator the kinetics of the exchange reactions between Br^- ion and PrBr, iso-BuBr and iso-PrBr were studied. The solvent was Me_2CO contg. 10% water by vol. E = 18.12, 20.21 and 22.94 kg.-cal., resp., and the effective collision diam. for iso-PrBr is unusually large. W. B. Keighton

The effect of mercuric bromide on the hydrolysis of alkyl bromides in acetone. Dennis R. Read and Wm. Taylor. *J. Chem. Soc.* **1939**, 1872–8.—Dissolved $HgBr_2$ accelerates the hydrolysis of MeBr, EtBr, iso-PrBr and *tert*-BuBr in aq. Me_2CO at 50°, the accelerating effect increasing markedly in the order given. Water has a smaller accelerating effect. Both water and $HgBr_2$ retard the esterification of an alc. with HBr. The HBr formed tends to deactivate the $HgBr_2$. The hydrolysis of *tert*-BuBr is also accelerated by AgBr, HBr, H_2O and *tert*-BuBr, the effect decreasing in that order, and all are less effective than $HgBr_2$. NaBr has no accelerating effect. $HgBr_2$ is an electrophilic reagent, water nucleophilic to MeBr, but increasingly electrophilic to *tert*-BuBr.
W. B. Keighton

Reaction velocity of aldehydes with ammonia. I. Reaction of furfural with ammonia. E. K. Nikitin and M. A. Abramova. *J. Gen. Chem.* (U. S. S. R.) **9**, 1347–55(1939); cf. *C. A.* **30**, 7496[6].—The concn. of furfural in H_2O is detd. with an accuracy of ±2% by treating at 12.5° 1 vol. of 1.5–3% furfural soln. with 2 vols. of a satd. Na_2CO_3 soln. in 7.5–8.5% NH_4OH, and comparing the rate of hydrofuramide pptn. with that of a standard soln. similarly treated. The results are calcd. by the formula previously given (*C. A.* **31**, 2126[8]). Lower concns. and the presence of aldehydes affect the results. C. B.

Catalytic hydration of carbon dioxide. Manfred Kiese and A. Baird Hastings. *J. Biol. Chem.* **132**, 267–80 (1940).—The velocity consts. for the hydration of CO_2 were measured by a manometric method. Br, HOBr, Cl and HOCl are strong catalysts for the hydration of CO_2, Br being stronger than Cl. They are particularly effective in the alk. range. I, HOI, halides, halates and perhalates have no significant catalytic effect. Sulfite and selenite are weaker catalysts than Cl and have an optimal activity between pH 7 and 8. Carbonic anhydrase is at least 10^3 times more active than an equal wt. of Br. The dissocn. const. of HOCl at 5° is $K' = 2.8 \times 10^{-8}$, and of HOBr at 5°, $K' = 1.0 \times 10^{-9}$. D. S. S.

Statistical fluctuations in autocatalytic reactions. Max Delbrück. *J. Chem. Phys.* **8**, 120–4(1940).—Math. The differential equations describing the statistical fluctuations of a simple autocatalytic reaction mechanism are set up and solved completely. G. M. Petty

Investigation of mixed oxidation-reduction catalysts. I. Mechanism of the activation of iron by copper. S. Kul'berg and E. Matenko. *J. Phys. Chem.* (U. S. S. R.) **13**, 600–4(1939).—Systems contg. benzidine, *o*-tolidine or *m*-phenylenediamine and Cu_2Cl_2 were oxidized by means of $FeCl_3$, and the course of the reaction was followed potentiometrically and colorimetrically. The simultaneous catalytic effect of Cu^{++} and Fe^{++} ions is greater than the sum of the individual effects, and the difference is greater the less stable the complex Cu-amine compd., in the order above given. Similar results were obtained with *p*-phenylenediamine, methylene blue and methyl violet.
F. H. Rathmann

Comparative characteristics of the adsorptive and catalytic properties of variously prepared synthetic ammonia iron catalysts. S. S. Gaukhman and V. A. Rolter. *J. Phys. Chem.* (U. S. S. R.) **13**, 593–9(1939); cf. *C. A.* **33**, 4386[5].—Adsorption isotherms for H and N on 2 Fe catalysts promoted by 2% Al_2O_3 are given for temps. from 184 to 425°. Phys. adsorption was found at 184°, two types of activated adsorption at 250–425° on the sintered catalyst only. For the ammonia synthesis at 360–385° the catalytic activity of the sintered catalyst was proportional to the activated adsorption. F. H. R.

Kinetics of the cyclization of biisobutyl over platinized charcoal. B. A. Kazanskii and A. L. Liberman. *J. Gen. Chem.* (U. S. S. R.) **9**, 1431–4(1939).—Because of the uniform rate of the catalytic aromatization of $(iso\text{-}Bu)_2$ over platinized C (with 14% and 20% Pt) at 300° by the method previously described (*C. A.* **33**, 9294[2]), the kinetic velocity of the reaction can be measured from the H liberated in the process. The mean apparent energy of activation of $(iso\text{-}Bu)_2$ (15,930–16,350 Cal./mol.) is nearly equal to the energy of activation of dehydrogenation (aromatization) of cyclohexane over the same catalyst (16,070 Cal./mol.) (cf. *C. A.* **30**, 6713[8]). C. B.

Activated carbon as a catalyst in certain oxidation-reduction reactions. Elmer C. Larsen and James H. Walton. *J. Phys. Chem.* **44**, 70–85(1940).—Activated C with reproducible catalytic properties was used to obtain more accurate data on factors affecting the rate of decompn. of H_2O_2 and the rate of autoxidation of $SnCl_2$ in acid soln. and of K urate in alk. soln. The rate of decompn. of H_2O_2 was followed by measuring the rate of O_2 evolution in a special app. (cf. *C. A.* **26**, 1850) for the following factors: (1) temp. of activation (activity reaches a max. for C activated at 825–875°), (2) source of C (lactose, dextrose, starch, and ash-free gelatin), (3) initial peroxide concn., (4) variation of quantity both of catalyst and of peroxide, (5) temp. of reaction, (6) pH, and (7) metallic salts. The decay in activity of C during H_2O_2 decompn. was investigated for (*a*) effect of moisture, and O_2, (*b*) maintaining const. concn. of peroxide and (*c*) repeated use of the same C. Detn. of the adsorption capacity for I_2 of carbons activated at different temps. showed a large increase in I_2 adsorption for high-temp. C owing to the combined effect of increased surface area and the formation of a new surface oxide. Results appear to agree with King's theory of the existence of 2 surface oxides on activated C—an alk. at high temps. and an acid at low temps. M. McMahon

Investigation of the lime-vanadium pentoxide system. A. N. Morozov. *Metallurg* **13**, No. 12, 21–8(1938). – Thermal and optical examn. of the $CaO\text{-}V_2O_5$ system contg. up to 50% CaO showed 3 compds., $CaO.V_2O_5$ m. 778°, $2CaO.V_2O_5$ m. 1015° and $3CaO.V_2O_5$ m. 1380°.
H. W. Rathmann

Application of physicochemical analysis to the study of the equilibria of the liquid phases in ternary systems. II. Layer separation in the systems: acetic acid–methylaniline–benzine (I) and acetic acid–dimethylaniline–benzine (II). E. F. Zhuravlev. *J. Phys. Chem.* (U. S. S. R.) **13**, 679–83(1939); cf. *C. A.* **34**, 3151.—Two ternary diagrams and 2 tables reproduce the data for the isotherms of these 2 systems at 20, 30, 40 and 45° and at 20, 25 and 30°, resp. In both cases the closed, concentric regions lie close to the AcOH-benzine side of the triangle as with the analogous aniline system. For I, the upper crit. ternary point is at 48.2°, for II at 41.7°; the long diams. of the "islands" correspond to 23% methylaniline, 77% AcOH for I and 20% dimethylaniline, 80% AcOH for II. No evidence was found for chem. compd. formation.
F. H. Rathmann

Determining the composition of solid phases of quaternary systems. V. I. Nikolaev. *Compt. rend. acad. sci. U. R. S. S.* **24**, 556–8(1939)(in English); cf. *C. A.* **31**, 3368[9].—Schreinemaker's method was applied to the quaternary mutual system $2NaCl + MgSO_4 \rightleftharpoons Na_2SO_4 + MgCl_2$, in which there are no solid solns., but where joint crystn. of 2 and 3 salts may be observed, and which contains a double salt, astrakhanite. The diagram is composed of 3 equilateral triangles which form half of a hexagon, with the H_2O point at the center and the $MgSO_4$, $MgCl_2$, NaCl and Na_2SO_4 points at the corners of the half hexagon. Four coördinates are used to calc. the compn. of liquid and solid phase and the motion is along a spiral. George Ayers

Derivation of the criteria for irreversible changes,

equilibrium and stability based on the uncompensated heat. Pierre Van Rysselberghe. *J. Chem. Education* **16**, 476–80(1939).—The second law of thermodynamics is expressed in terms of the uncompensated heat. The significance of this quantity and its connection with the work of irreversible cycles is considered. All the particular criteria for irreversible changes are derived from the fundamental one which states that in no natural process can the uncompensated heat be neg. The corresponding criteria of equil. and stability are established with special attention being paid to Gibbs' criteria. The chem. variable is defined and used in establishing new and convenient forms for the criteria of equil. and stability.
Kenneth H. Slagle

Entropy of dimethylacetylene from low-temperature calorimetric measurements. Free rotation in the dimethylacetylene molecule. Darrell W. Osborne, Clifford S. Garner and Don M. Yost. *J. Chem. Phys.* **8**, 131(1940).—The molal entropy of MeC:CMe at 291.00°K. and 536 mm. is 68.14 cal./deg. mole from calorimetric data, and 67.82 cal./deg. mole from mol. data. This close agreement indicates that there is no appreciable barrier restricting the rotation of the Me groups with respect to each other.
G. M. Petty

The exact formulas for the true and mean specific heats of platinum between 0° and 1600°. F. M. Jaeger and E. Rosenbohm. *Physica* **6**, 1123-5(1939).—Selected data based on 600 detns. of the mean sp. heats and the heat content of pure Pt between 0° and 1600° yielded the following: between 0° and 500°, $Q_{t°-0°} = 0.031357\,t + 0.04507 \times 10^{-4}\,t^2 - 0.0161 \times 10^{-7}\,t^3$, between 400° and 1600°, $Q_{t°\ 0°} = 0.031622\,t + 0.03172 \times 10^{-4}\,t^2$. The mean sp. heats between 20 and 400° are

t	$\bar{C}_{p_{t°-20°}}$
100	0.03187
200	0.03228
300	0.03264
400	0.03296

and between 400° and 1600°, $\bar{C}_{p_{t°-20°}} = 0.031701 + 0.03164 \times 10^{-4}\,t$.
Earl H. Brown

Specific heat of ethyl ether, nitrobenzene and carbon disulfide. Josef Mazur. *Z. Physik* **113**, 710–20(1939); cf. *C. A.* **33**, 8099[3,4].—The sp. heat in cal./g. (C_p) of nitrobenzene in the temp. range 5–20° is given by $0.338300 + 0.000556\,t$. C_p for Et_2O in the temp. range −100° to 20° is given by $0.54239 + 0.0005956\,t$. C_p for CS_2 in the range −100° to 20° is given by $0.22674 + 0.0007731\,t + 0.00000431\,t^2$. No evidence of any transition point was found.
E. J. Rosenbaum

Heat of fusion of ice. A revision. Nathan S. Osborne. *J. Research Natl. Bur. Standards* **23**, 643–6(1939)(Research Paper No. 1260).—A revision of the results of measurements made at the Natl. Bur. Standards in 1913 and 1915; more recent data for the heat capacity of water were used. The revised value is 333.5 ± 0.2 intern. joules/g.
John W. Knowlton

Heat of oxidation of the iodide anion by potassium dichromate. T. V. Ass, A. Kh. Batalin and I. A. Shcherbakov. *J. Phys. Chem.* (U. S. S. R.) **13**, 687–9(1939).—The heat of reaction for $KI + K_2Cr_2O_7 + H_2SO_4$ (I) is 28 Cal. per g. atom of I; for $KI + K_2Cr_2O_7 + HCl$ (II), *II* is 26 Cal. The velocity const. for I is 1st order, *K* 0.13; for II, *K* decreases as the reaction proceeds.

3—SUBATOMIC PHENOMENA AND RADIOCHEMISTRY

A. B. F. DUNCAN

Scattering of light in Bose-Einstein and Fermi-Dirac gas. B. N. Singh. *Phil. Mag.* **28**, 635–41(1939).—The modification produced by quantum phenomena in the classical expression for light scattering is calcd. For the non-degenerate case the effect of the Bose-Einstein and Fermi-Dirac statistics is to increase or decrease, resp., the classical scattering coeff. For the degenerate case the Bose-Einstein scattering tends to infinity, while the Fermi-Dirac scattering tends to zero. E. J. Rosenbaum

The electron as ring, magnet and top. Johannes Stark. *Tech. Blätter* **29**, 207–8(1939).—A review. R. Seiden

Radiation from a point charge revolving in a circular orbit. Hillel Poritsky. *Phil. Mag.* **28**, 617–31(1939).—Math. E. J. Rosenbaum

The propagation of electron waves in ionic single crystals. A. Von Hippel and J. W. Davisson. *Phys. Rev.* **57**, 156–7(1940). G. M. Petty

Shape of β-ray spectra and the mass of neutrino. L. A. Sliv. *Compt. rend. acad. sci. U. R. S. S.* **24**, 34–7 (1939)(in English).—Math. The Konopinski-Uhlenbeck (*C. A.* **29**, 6833[7]) formula for the energy distribution is modified, giving closer agreement with expt., particularly near the upper limit of the spectrum. Theory and expt. are compared for β-spectra of Ra E, Th C, P^{32}, N^{13} and Th C. On a log λ versus log $(E_m - 1)$ diagram, the new formula is shown to be intermediate between the K.-U. and the Fermi formulas. G. M. Petty

β-Decay and mesotron lifetime. Robert Serber. *Phys. Rev.* **56**, 1065(1939).—It is shown that there is no theoretical connection between β-decay and mesotron decay; both can occur, but they are completely independent processes. G. M. Petty

Meson theory of nuclear forces. H. A. Bethe. *Phys. Rev.* **55**, 1261–3(1939).—Theoretical. Present evidence is in favor of the "neutral theory," rather than the sym. theory. G. M. Petty

Binding energy of He^6 and nuclear forces. H. Margenau. *Phys. Rev.* **55**, 1173–5(1939).—Math. The energy difference $He^6 - Li^6$ is calcd. Conclusions are drawn concerning the detailed nature of the spin forces. G. M. Petty

Many-body interactions in atomic and nuclear systems. H. Primakoff and T. Holstein. *Phys. Rev.* **55**, 1218–34 (1939).—Math.-theoretical. The replacement of field interactions by two-body action-at-a-distance potentials is a poor approximation in nuclear problems. A satisfacory description of nuclei, other than the deuteron, can be obtained only by an explicit consideration, from the very beginning, of the role played by the field. G. M. P.

Coulomb energies and nuclear models. Harrison Brown and D. R. Inglis. *Phys. Rev.* **55**, 1182–3(1939).—Electrostatic energy differences of isobaric light nuclei estd. by use of the α-model do not agree with expt. as well as those given by Bethe (*C. A.* **32**, 8924[4]) for the central model. The comparison with expt. of the binding energies of alphas in the light 4 *n*-particle nuclei, given by Hafstad and Teller for the α-model (*C. A.* **33**, 1206[3]), is improved by inclusion of the Coulomb energy. G. M. Petty

The neutron's magnetic moment. O. Halpern and M. H. Johnson. *Phys. Rev.* **57**, 160(1940); cf. *ibid.* **55**, 601, 1125(1939); *C. A.* **33**, 6700[7].—A general discussion. G. M. Petty

The neutron-deuteron scattering cross section. Lloyd Motz and Julian Schwinger. *Phys. Rev.* **57**, 161–2(1940).—Math. The scattering cross section is 4.57×10^{-24} sq. cm. At best, this theoretical value is 20% too large. The discrepancy is due to polarization effects. G. M. Petty

The magnetic moments of light nuclei. M. Phillips. *Phys. Rev.* **57**, 160–1(1940).—Discrepancies between theoretical and exptl. values of nuclear magnetic moments are discussed. G. M. Petty

Multiple scattering of charged particles. Arthur E. Ruark. *Phys. Rev.* **57**, 62(1940).—Math. G. M. P.

A note on the wave functions of the relativistic hydrogenic atom. Leverett Davis, Jr. *Phys. Rev.* **56**, 186–7 (1939).—The normalized radial wave functions for the discrete levels of Dirac's relativistic hydrogenic atom are expressed in terms of generalized Laguerre polynomials. A general expression for the av. value of r^q is given. H. C. Thomas

The calculation of polarizabilities and van der Waals forces for atoms in *S* states. Julian K. Knipp. *Phys. Rev.* **55**, 1244–54(1939).—Math. The perturbation scheme of Møller and Plesset (*C. A.* **29**, 993[3]) is extended to the calcn. of at. polarizabilities and van der Waals force consts. The at. polarizabilities of Be and A are 4.14 and 1.28×10^{-24} cc., resp. The const. μ in the van der Waals energy, $-\mu/R^6$, is 222 and 63.7×10^{60} erg cm.^{6} for 2 Be atoms and for 2 A atoms, resp. The observed at. polarizability of A is 1.63×10^{-24} cc. G. M. Petty

Relative intensity of spectrum lines. F. H. Newman. *Phil. Mag.* **28**, 584–7(1939).—In an elec. discharge in the vapor of alkali amalgams the emission lines of the alkali component show a marked increase in intensity relative to the Hg lines as the temp. is raised. At const. temp. with an uncondensed discharge the alkali lines are relatively strong but with a condensed discharge they may be suppressed, leaving only the Hg lines. The explanation of these observations is discussed. E. J. Rosenbaum

Electric glow between carbon electrodes. F. H. Newman. *Phil. Mag.* **28**, 544–7(1939).—When a glow discharge is passed at low gas pressures between very pure C electrodes with a p. d. of 40 v. the luminosity fills the whole space surrounding the ends and the electrodes are not incandescent. The neg. electrode becomes pitted and covered with amorphous C and the glow becomes difficult to restart. A comparison of the glow spectrum with that of an elec. discharge under the same conditions indicates that the excitation potential of the Ångström bands is higher than that for the Swan, CN and CH bands. E. J. Rosenbaum

Theory of the cathodic-discharge portion of a low-pressure discharge. III. W. Weizel, R. Rompe and M. Schön. *Z. Physik* **113**, 730–9(1939); cf. *C. A.* **33**, 8488[8]. —Equations for the neg. glow are set up, considering as elementary processes the production of charge carriers by electron impact, the recombination, and the motion of the carriers in the field. These equations are solved by an approximation method. E. J. Rosenbaum

Electric strength of gases measured by corona discharge. W. M. Thornton. *Phil. Mag.* **28**, 666–78(1939). —The voltage at which a corona discharge starts on a wire was measured for 43 gases as a function of wire diam. and gas pressure. From these values the gradient in kv./cm. which just starts a glow in each gas at 1 atm. and 0° was computed and graphed against the reciprocal of the electron mean free path. The points lie along 6 straight lines of different slopes. The results are not related to the ionizing potentials of the gases or to electron configurations. Cl has the greatest elec. strength of the gases examd.; the monat. gases have the least. When Cl is substituted for H in a hydrocarbon the elec. strength is increased. E. J. Rosenbaum

Breakdown, glow discharge and photoelectric reaction. W. Rogowski. *Z. Physik* **114**, 1–52(1939); cf. *C. A.* **33**, 7186[9].—Theoretical. The photoelec. theory of breakdown is extended to include vol. ionization. In several respects the theory is similar to that for breakdown by pos. ionization; e. g., the transition from breakdown to glow discharge is qualitatively the same for both. The space charge can stabilize the discharge for sufficiently strong photoelec. reaction. E. J. Rosenbaum

The β-ray spectra of phosphorus, sodium and cobalt. J. L. Lawson. *Phys. Rev.* **56**, 131–6(1939).—The β-ray spectra of P^{32}, Na^{24} and Co were obtained by means of a magnetic spectrometer of high resolving power (1.6% momentum spread). The max. energies of the electrons from P and Na are 1.72 and 1.4 m. e. v., resp. The spectrum of the Co positrons, which have a max. energy of 1.50 m. e. v., suggests more than 1 continuous distribution. The effect of scattering is investigated. The results agree more nearly with the Fermi (*C. A.* **28**, 5329[1]) theory of β-decay than with that of Konopinski and Uhlenbeck (*C. A.* **29**, 6833[7]). The resolution of the spectrometer is illustrated by the sepn. of the *K* and *L* shell conversion electrons arising from a γ-ray in In. H. C. Thomas

Effect of pressure on the positive point-to-plane discharge in N_2, O_2, CO_2, SO_2, SF_6, CCl_2F_2, A, He and H_2. H. C. Pollock and F. S. Cooper. *Phys. Rev.* **56**, 170–5 (1939).—Curves are given showing the variation with abs. pressure over a range of 30 atm. of the d.-c. voltages at which corona and spark breakdown appear in a 3-mm. point-to-plane gap in H_2, A, air, CCl_2F_2, O_2, He, 50% O_2—50% He, 25% O_2—75% He, 25% O_2—75% A, 50% O_2—50% N_2, SF_6, CO_2. Voltage max. appear in the breakdown curves for point potential in air, CCl_2F_2, A, the mixts. SF_6 and CO_2. In the gases which readily form neg. ions there is found a stabilization of the corona, which is not effective at all pressures. The effect of x-ray irradiation on the gap strength is detd. and discussed. H. C. T.

The variation with the density of mercury vapor of the intensity of the spectral lines of mercury excited by electron impact. O. S. Duffendack and O. G. Koppius. *Phys. Rev.* **55**, 1199–1208(1939).—A source which closely approximates an ideal source—one in which electrons of definite and controlled energy are projected so that no electron makes more than one exciting or ionizing collision in its passage through the gas—is described. Theoretical formulas were developed which closely approximate the observed relation between the intensity of the Hg lines and the d. of the Hg vapor. Data and curves are also given for mixts. with A and with He. An analytical curve for the detn. of Hg in these mixts. can be derived from the data. These results are of immediate value in the practice of quant. spectrochem. analysis. G. M. Petty

The secondary emission from evaporated nickel and cobalt. D. E. Wooldridge. *Phys. Rev.* **56**, 1062–3 (1939); cf. *C. A.* **33**, 9132[8].—The secondary yield (0–1.5) was plotted against the primary energy (0–1000 e. v.) for Ni and Co evapd. at less than 2×10^{-7} mm. Hg. Theoretical curves fit the exptl. data very closely. G. M. P.

The "photo gas-kinetic effect." Maximilian Plotnikov, Jr. *Acta Phys. Polon.* **4**, 195–204(1935); *Chem. Zentr.* **1938, I**, 528; cf. *C. A.* **32**, 6166[7].—The previously described thermophotometric method for the measurement of radiant energy, which depends upon the "photo gas-kinetic effect," was further developed experimentally. Since the quartz shutter plate previously used absorbs completely wave lengths greater than 5 μ, a KCl plate was used, the transparency of which extends to 24 μ. The production of this plate and the app. used for the purpose are described in detail. It is possible to produce optically clear crystal calottes 7–8 cm. in diam. from which plates and prisms of the desired size can be cut. With this improved app., the transformation coeff. of the system platinized Pt-air-KCl-plate was detd. A value of 1.43% is reported. The possibility of further increasing the sensitivity of the method by the use of platinized Pt wire gauze or of graphite foil is explained. The arrangement of app. described reacts to heat radiated from the hand as well as to that radiated from water at a temp. slightly different from that of the room. M. G. Moore

Increasing the sensitivity of the thermophotometric method for the measurement of radiated energy. Maximilian Plotnikov, Jr. *Acta Phys. Polon.* **6**, 12–18(1937); *Chem. Zentr.* **1938, I**, 942; cf. preceding abstract.—Further work is reported on the previously described method (cf. *C. A.* **28**, 2228[8]) for the measurement of radiated energy by the conversion of such energy into kinetic energy. Various receiving targets for the radiation are described, the conversion coeffs. of which were detd. The greatest sensitivity was shown by graphite foils, less was shown by smoked or platinized Pt gauze, and still less by platinized Pt disks. M. G. Moore

Electron-diffraction examination of oxide films on light metals. Itirō Iitaka and Sigeto Yamaguti. *Nature* **144**, 1090–1(1939).—Mg, after polishing, is covered with an oxide film at room temp. and at 400°. There is an oxide film on Al, but no film on Be. G. M. Petty

A report on the development of the electron supermicro-

scope at Toronto. E. F. Burton, J. Hillier and A. Prebus. *Phys. Rev.* **56**, 1171–2(1939); cf. *Can. J. Research* **17, A**, 49–63(1939).—Improvements in the app., which reduce the resolving limit below 60 A., are described. G. M. Petty

Changes in the internal resistance of selenium barrier-layer cells caused by exposure to light. Arne Eld Sandström. *Phil. Mag.* **28**, 642–8(1939); cf. *C. A.* **32**, 5300[8]; **33**, 1602[8].—The resistances of 2 cells were measured before and after exposure to visible light, soft x-rays (3.5 to 20 A.) and hard x-rays (0.3 to 1.0 A.). The ratio of resistances after and before exposure is about 0.8 independent of voltage, and the change in resistance is of the same character for the various radiations. Both cells showed the same type of resistance increase on storage in darkness. A non-rectifying cell has the same resistance before and after exposure, and the changes noted are attributed to changes in the barrier-layer. E. J. Rosenbaum

The β- and γ-radiations from copper^{61} and europium^{152}. A. W. Tyler. *Phys. Rev.* **56**, 125–30(1939).—These radiations are studied with the aid of a magnetic spectrometer of high resolution. The max. energy of the Cu^{64} positrons is found to be 0.659 ± 0.003 m. e. v., that of the Cu^{64} electrons is 0.578 ± 0.003 m. e. v. The effect on the shape of the spectra of scattering within the source and from its support is studied. The spectra from thin sources support the Fermi theory of β-decay. Electrons from Eu^{152} have a max. energy of 1.885 ± 0.012 m. e. v. The energies of 3 of the β-rays of Eu are 0.123 ± 0.001, 0.163 ± 0.001 and 0.725 ± 0.003 m. e. v. H. C. Thomas

The absorption of mesotrons in air and in condensed materials. Enrico Fermi. *Phys. Rev.* **56**, 1242(1939).—The absorption of mesotrons by air is considerably larger than the absorption by equal masses of condensed materials. From one-half to all this difference is theoretically explained without any contribution from the decay of the mesotron. G. M. Petty

A new proof of the instability of the mesotron. Giuseppe Cocconi. *Phys. Rev.* **57**, 61–2(1940).—The data of Clay and van Gemert (*C. A.* **33**, 7188[6]) on the Pb absorption of those cosmic rays which come at an angle of 60° to the zenith were verified. The results can be explained by the instability of the mesotron. G. M. Petty

A measurement of mesotron lifetime. W. M. Nielsen, C. M. Ryerson, L. W. Nordheim and K. Z. Morgan. *Phys. Rev.* **57**, 158(1940).—By the use of data on the absorption of vertical cosmic radiation by Pb, the lifetime of the mesotron is calcd. to be 1.2×10^{-6} sec. The mean free path is 7×10^5 cm. G. M. Petty

Evidence for the occurrence of meson pairs. H. J. J. Braddick and G. S. Hensby. *Nature* **144**, 1012–13(1939).—Cloud-chamber photographs (2358) of cosmic-ray particles were taken under 30 m. of clay, with 3 different arrangements of Pb inside and outside the chamber; 80% show a single ray penetrating a Pb plate without appreciable deviation; most of these are mesons. 125 show evidence of electronic showers. In 5 photographs, 2 apparently assocd. particles go through the Pb plate without change of direction and without producing secondaries; these are meson pairs. G. M. Petty

Simultaneous penetrating particles in the cosmic radiation. G. Wataghin, D. de Souza Santos and P. A. Pompeia. *Phys. Rev.* **57**, 61(1940). G. M. Petty

Baade and Zwicky's theory of cosmic rays, and the helium content of beryls. John Read. *Nature* **144**, 1040 (1939).—Baade and Zwicky (*Proc. Natl. Acad. Sci. U. S.* **20**, 259(1934); *Astrophys. J.* **88**, 411(1938)) have suggested that the av. intensity of cosmic radiation is perhaps 35 times the present rate. If this is true, the exptl. evidence regarding the He content of beryls is not incompatible with the assumption that this He was produced by cosmic rays. The possibility of biol. effects due to cosmic rays would also need reconsideration. G. M. Petty

Investigation of cosmic-ray showers of atmospheric origin, using two cloud chambers. A. C. B. Lovell and J. G. Wilson. *Nature* **144**, 863–4(1939).—Data are given for cosmic-ray showers, obtained in 2 cloud chambers sepd. (1) horizontally by 5.5 and 19 m., and (2) vertically by 36 cm. Al and by 36 cm. Pb. From the small av. multiplication involved when Pb or Al is interposed between the chambers, and from the form of the cascade spectrum in air, it is shown that large showers will be relatively much more frequent in light elements than is indicated by the cascade theory applied to a single entrant particle. G. M. P.

Nature of cosmic-ray particles. Seth H. Neddermeyer and Carl D. Anderson. *Rev. Modern Phys.* **11**, 191–207(1939).—The principal methods are reviewed for the detn. of mass. Cloud-chamber expts. are made on the no. of secondaries ejected from 1 cm. of Pt by "single" primaries with momenta greater than 500 m. e. v. A large predominance of single neg. secondaries over positives and showers is found. An energy analysis indicates that the data are not easily explainable by assuming 200-*m* mesotrons and electrons. Some of these energies (>150 m. e. v.) may be explained by particles of smaller mass than 200 *m* and hence smaller energy losses on traversing matter. Earl A. Gulbransen

Evidence that protons are the primary particles of the hard component. Thomas H. Johnson. *Rev. Modern Phys.* **11**, 208–10(1939).—A review. 16 references. Earl A. Gulbransen

Recent studies at high elevations. S. A. Korff. *Rev. Modern Phys.* **11**, 211–19(1939).—A review. 22 references. Earl A. Gulbransen

Recent studies at high elevations. J. C. Stearns and D. K. Froman. *Rev. Modern Phys.* **11**, 220–1(1939); cf. *C. A.* **32**, 4424[6].—Results indicate that high-energy neutral radiation may be produced in Pb by cosmic radiation. Earl A. Gulbransen

Specific ionization of high-speed particles. Robert B. Brode. *Rev. Modern Phys.* **11**, 222–9(1939).—A review. Earl A. Gulbransen

Nature of cosmic rays below ground. Volney C. Wilson. *Rev. Modern Phys.* **11**, 230–1(1939); cf. *C. A.* **33**, 6140[8].—A review. Earl A. Gulbransen

Analysis of deep rays. Pierre Auger and Thérèse Grivet. *Rev. Modern Phys.* **11**, 232–4(1939).—A study is made of the relative proportion of soft and hard particles and their space distribution in cosmic radiation. An arrangement of counters is used in which one of the counters is protected from secondaries. A much higher proportion of soft particles is obtained than that found with the free counter arrangement. The deepest laboratory was equiv. to 75 m. of H_2O. Earl A. Gulbransen

Energy distribution and positive excess of mesotrons. Haydn Jones. *Rev. Modern Phys.* **11**, 235–8(1939).—A vertical cloud chamber is used to obtain the energy spectrum of penetrating cosmic rays (0.2×10^9 e. v. to 10×10^9 e. v.). The soft component was eliminated by absorption in a 10.2 cm. Pb shield. Comparison is made between the exptl. results and Euler's theoretical curve (*C. A.* **33**, 4634) for the hard component. More pos. mesotrons (about 29%) than negative were found for each energy. Earl A. Gulbransen

Showers produced by penetrating rays and allied phenomena. W. F. G. Swann. *Rev. Modern Phys.* **11**, 242–54 (1939); cf. *C. A.* **33**, 8103[8].—A description of an app. for recording showers produced by penetrating rays. Counters (180) arranged in trays of 18 each are connected to 180 electroscopes. A sheet of Pb is interposed between each tray of counters. The optical system is arranged so that each electrometer indicates its position in the system by a spot on a ground-glass screen. The elec. system is arranged so that no electroscope discharges unless one counter in each tray discharges simultaneously. Results obtained from the intensity zenith angle observations and the intensity altitude observations made by recent stratosphere balloon flights are given: (a) at higher altitudes the diminution of intensity with increase of zenith angle from the vertical was much less rapid than expected, (b) at an atm. depth of 2 meters of H_2O (equiv.), the horizontal intensity formed 25% of the vertical, while for a depth of 0.5 meters of H_2O the corresponding result was 80%. Earl A. Gulbransen

Behavior of high-energy electrons in cosmic radiation. C. G. Montgomery and D. D. Montgomery. *Rev. Modern Phys.* **11**, 255–64, 266(1939).—A discussion of the behavior of electrons and photons of high energy in the production of large bursts of cosmic radiation and the occurrence of nuclear "vaporizations." E. A. G.

Behavior of high-energy electrons in cosmic radiation. J. R. Oppenheimer. *Rev. Modern Phys.* **11**, 264–6(1939). —A discussion of the relative frequency of large bursts in different materials from the cascade theory. Earl A. Gulbransen

Burst frequency as a function of energy. Marcel Schein and Piara S. Gill. *Rev. Modern Phys.* **11**, 267–76 (1939).—Size frequency distributions of bursts were obtained from analyses of records made by Carnegie model C cosmic-ray meters (shielded by 12-cm. Pb) at different locations. The value of 10^{-4} was found for the creation probability of a burst by a mesotron of about 2×10^{10} e. v. energy in a thickness of 12 cm. of Pb. This leads to a cross section per nuclear particle (proton, neutron) of 2×10^{-30} sq. cm. This value is independent of the energy of the incident particle. The effect of altitude on the frequency of large bursts is discussed. E. A. G.

Recent experiments on cosmic rays. P. M. S. Blackett and B. Rossi. *Rev. Modern Phys.* **11**, 277–81(1939).—Preliminary results are briefly described for the following expts.: shower production by penetrating cosmic rays, origin of the ionization bursts, absorption of penetrating cosmic-ray particles in Au, the non-ionizing component of cosmic radiation, and second max. of the transition curve for showers. Earl A. Gulbransen

Recent experiments on cosmic rays. J. Clay. *Rev Modern Phys.* **11**, 281(1939); cf. *C. A.* **33**, 7188[6,7], 9122[1]. The decrease of radiation in the directions 0°, 60° and 75° from the vertical is measured as a function of the thickness of Pb interposed between the coincidence counters. The decrease is very different for rays from different directions. The results are in agreement with calcns. for 0° and 60° if 20 km. is taken for the layer of formation, an original energy distribution proportional to $E^{-2.93}$, and a lifetime between 1.7 and 2×10^{-6}. The agreement in the 75° direction is not satisfactory. E. A. G.

Narrow cosmic-ray showers. W. Bothe. *Rev. Modern Phys.* **11**, 282–7(1939).—A review. 20 references listed. Earl A. Gulbransen

Narrow cosmic-ray showers. J. Clay. *Rev. Modern Phys.* **11**, 287(1939); cf. preceding abstr. and Schmeiser and Bothe, *C. A.* **32**, 4872[7].—Expts. are made to check the second max. of showers under Pb by taking small-angle showers. A second max. measurement with coincident counters is found but smaller than that for expts. performed with the larger angle. The second max. is not as large as that found by S. and B. E. A. G.

Extensive cosmic-ray showers. Pierre Auger, P. Ehrenfest, R. Maze, J. Daudin, Robley and A. Fréon. *Rev. Modern Phys.* **11**, 288–91(1939).—A continuation of the study of air showers by the method of long-distance coincidences and Wilson cloud-chamber measurements. Earl A. Gulbransen

Mesotron production in the atm. Marcel Schein and Volney C. Wilson. *Rev. Modern Phys.* **11**, 292–5(1939).—A Rossi-Hsiung type expt. is made up to an altitude of 25,000 feet with four-fold coincident counters. An 8.1-cm. Pb sheet is placed between the counters and a 2.2-cm. Pb sheet alternately changed from a position above to one between the counters. From the difference between counting rates it was found that at 25,000 feet an av. of 2 ionizing particles is ejected in a forward direction by a Pb plate (38 cm. × 5.2 cm. × 2.2 cm.) by the action of photons. This leads to a cross section per proton for the creation of a mesotron by a photon of $\varphi_p \simeq 3 \times 10^{-27}$ sq. cm. Earl A. Gulbransen

Disintegration of mesotrons. Bruno Rossi. *Rev. Modern Phys.* **11**, 296–303(1939).—The variation of the hard component of cosmic rays with the zenith angle and the temp. effect indicates that the cosmic-ray mesotrons decay with a lifetime of 3×10^{-6}. Other phenomena considered (variation with height, barometer effect, shape of the energy spectrum, no. of secondaries, etc.), are not inconsistent with the lifetime assumed. There is no evidence that the mesotrons which have been stopped actually disintegrate into an electron and a neutrino. Earl A. Gulbransen

Scattering of slow neutrons by protons. Milton S. Plesset and Frederick W. Brown. *Proc. Natl. Acad. Sci. U. S.* **25**, 600–4(1939).—Math.-theoretical. The scattering of slow neutrons by protons is considered for the spherical-well potential and for the meson-type potential. Calcns. are made for the potential hole; the assumption frequently made that the interaction is of negligible width leads to appreciable inaccuracies. The introduction of the virtual level of the deuteron to describe the singlet scattering is also considered, and the sequence of virtual levels defined by the Kapur and Peierl's scattering procedure (*C. A.* **33**, 4119[9]) is detd. to illustrate the convergence of the method in the extreme case of the deuteron. G. M. Petty

Fast neutron measurements with recoil counters. S. A. Korff. *Phys. Rev.* **56**, 1241–2(1939); cf. *C. A.* **33**, 6142[1]. —The counting rate of a recoil counter in the presence of a Ra + Be neutron source as a function of voltage (1450–1950 v.) is shown graphically. No β- or γ-rays are counted below 1770 v.; all are counted above 1850 v. There is no plateau: the counting rate rises steadily with the voltage. This counter was used in studying the neutrons in cosmic radiation. G. M. Petty

Elastic collisions of protons and very fast neutrons. Mokitiro Nogami. *Sci. Papers Inst. Phys. Chem. Research* (Tokyo) **36**, 244–50(1939).—The angular distributions and elastic cross-sections have been calcd. for neutrons whose energies are 15, 25, 30 and 35 m. e. v. Math. Helen S. Hopfield

A study of the diffraction of protons of medium energy by vapor molecules. H. J. Yearian. *J. Chem. Phys.* **8**, 24–8(1940).—The diffraction of 15–20-kv. protons by CCl_4 vapor was investigated. The principal difficulties encountered were with space-charge dispersion of the beam near the ion source, and with neutralization of the beam as it passed through the vapor. Cross sections for neutralization and reionization of protons (in H, air, CCl_4 and EtOH) and H mol. ions (in H, air, and CCl_4) were detd. The sensitivity of photographic film (Eastman Commercial Ortho) decreased rapidly as the film was outgassed, probably owing to loss of water, but increased 15 times when the film was treated with oil. Diffraction patterns showed 3 max., with measurements in satisfactory agreement with electron diffraction data. G. M. Petty

High-velocity atomic beams. I. Amdur and H. Pearlman. *J. Chem. Phys.* **8**, 7–12(1940).—A general method is developed for producing and for measuring the intensity of high-velocity at. beams. The app. is described. The method is applied to beams of H atoms with energies equiv. to 200- to 800-v. electrons. Measurement of the collision cross section of these atoms when scattered by mol. H confirms the prediction that such scattering is predominately due to repulsive forces between the beam and scattering particles. G. M. Petty

Diffuse radiation of neutrons in the cyclotron. D. G. Alkhazov, I. V. Kurchatov, M. G. Meshcheryakov and V. N. Rukavishnikov. *Compt. rend. acad. sci. U. R. S. S.* **24**, 32–3(1939)(in French).—The effect of the dimensions of the accelerating chamber, the gas pressure and the magnetic field on the yield and energy of neutrons is discussed. Diffuse neutrons are due to the D + D reaction. G. M. Petty

Helium of mass three as an agent in nuclear reactions. Walter H. Barkas. *Phys. Rev.* **56**, 1242–3(1939).—Theoretical. The amt. of energy released by reactions involving He^3 is estd.: $H^2 \rightarrow Li^4$, $Li^6 \rightarrow B^8$, $Li^7 \rightarrow B^9$, $B^{10} \rightarrow N^{12}$, $C^{12} \rightarrow O^{14}$, $N^{14} \rightarrow F^{16}$, $O^{16} \rightarrow Ne^{18}$, $Ne^{20} \rightarrow Mg^{22}$, $Mg^{24} \rightarrow Si^{26}$, $Al^{27} \rightarrow P^{29}$, $Si^{28} \rightarrow S^{30}$, $Si^{29} \rightarrow S^{31}$, $P^{31} \rightarrow Cl^{33}$, $S^{32} \rightarrow A^{34}$, $S^{33} \rightarrow A^{35}$, $Cl^{35} \rightarrow K^{37}$, $A^{36} \rightarrow Ca^{38}$. Many of these product nuclei cannot be formed by any other process. G. M. Petty

α-Particle groups from the disintegration of beryllium by deuterons. Samuel K. Allison, Elizabeth R. Graves

and Lester S. Skaggs. *Phys. Rev.* **57**, 158(1940).—The reaction $Be^9(d,\alpha)Li^7$ was investigated, with Po, Be and C targets. There is an excited state of Li^7 at 0.48 m. e. v. G. M. Petty

Mass and stability of C^{14}. Ernest Pollard. *Phys. Rev.* **56**, 1168(1939).—When C is bombarded with 3-m. e. v. deuterons, a group of protons with the range 82.0 cm. is observed. The reaction is $C^{13} + D^2 \rightarrow C^{14} + H^1$; the energy change is +8.21 m. e. v.; the mass of C^{14} is 14.00780 ± 0.00020. C^{14} should emit an electron with an energy of 0.3 m. e. v.; it was not detected. G. M. P.

Pair emission in the proton bombardment of fluorine. J. R. Oppenheimer and J. S. Schwinger. *Phys. Rev.* **56**, 1066–7(1939).—A theoretical treatment is given for the data of Fowler and Lauritsen (*C. A.* **34**, 672[9]). G. M. Petty

A study of the protons from calcium under deuteron bombardment. Wm. L. Davidson, Jr. *Phys. Rev.* **56**, 1061(1939).—Upon bombarding CaO with 3.1-m. e. v. deuterons, groups of protons due to $Ca(d,p)$ were observed at 66 and 96 cm., corresponding to "Q" values of 4.51 and 6.30 m. e. v. The 66-cm. group is due to the reaction $Ca^{40} + H^2 \rightarrow Ca^{41} + H^1$. G. M. Petty

Evidence for incorrect assignment of the supposed Si^{27} radioactivity of 6.7-minute half-life. H. A. Bethe and W. J. Henderson. *Phys. Rev.* **56**, 1060–1(1939).—Three radioactive elements have been reported to result from the natural α-particle bombardment of Mg. One with 2.36 min. half-life emits neg. electrons: $Mg^{25}(\alpha,n)$. This assignment was verified. An activity of 11-min. half-life, originally assigned to Al^{29}, is probably due to an impurity. A positron activity of 6.7-min. half-life was assigned to Si^{27}: $Mg^{24}(\alpha,n)$. With 16-m. e. v. α-particles and very pure Mg, no positron activity, but only a neg. electron activity, was observed. The 6.7-min. activity is shown to be $Al^{29}.Mg^{26}(\alpha,p)$. Kuerti and Van Voorhis have found that Si^{27} has a half-life of 3.7 sec. (*C. A.* **33**, 9125[2]). The energy relations are reviewed. G. M. Petty

Internal conversion in 6.4-hour cadmium. R. G. Sachs. *Phys. Rev.* **57**, 159–60(1940).—It is demonstrated that the data and conclusions of Valley and McCreary (*Ibid.* **56**, 863) are not inconsistent with theory. G. M. Petty

The radioactivity of Mn^{56}. R. H. Bacon, E. N. Grisewood and C. W. Van der Merwe. *Phys. Rev.* **56**, 1168(1939).—The γ-rays from Mn^{56} fit an energy group with an extrapolated end point of 1.50–1.75 mc^2, indicating a γ-ray line at 600–700 e. kv. There is marked straggling out to 3.90 mc^2, indicating a γ-ray line at 1.7 m. e. v. The data of other workers indicate that there are other lines between these two. G. M. Petty

A study of the protons from vanadium, copper, manganese and scandium under bombardment by deuterons. Wm. L. Davidson, Jr. *Phys. Rev.* **56**, 1062(1939).—The following reactions were produced by 3.1-m. e. v. deuterons: $V^{51} + H^2 \rightarrow V^{52} + H^1$; Cu^{63}, $Cu^{65} + H^2 \rightarrow Cu^{64}$, $Cu^{66} + H^1$; $Mn^{55} + H^2 \rightarrow Mn^{56} + H^1$; $Sc^{45} + H^2 \rightarrow Sc^{46} + H^1$. Measurements and calcns. were made for V^{52}, Cu^{64} and ^{66}, Mn^{56} and Sc^{46} for the range of proton groups in air equiv., "Q" values, excitation levels and mass. The mass of Mn^{55} is 54.9643. G. M. Petty

Radioactive isotopes of indium from α-bombardment of silver. L. D. P. King and W. J. Henderson. *Phys. Rev.* **56**, 1169(1939); cf. *Ibid.* **55**, 1118.—Ag was bombarded with 16-m. e. v. α-particles. The 20-min. period is assigned to $Ag^{109}(\alpha,n)In^{112}$. The 72-sec. period from In plus fast neutrons and from In + γ was not observed. The 65-min. period is assigned to $Ag^{107}(\alpha,n)In^{110}$. A weak activity of 9 hrs. was traced to an impurity: $Cu^{63}(\alpha,n)$-Ga^{66}. Less than 0.01% Cu in Ag could be detected by this means. These three activities were identified chemically. Another weak period of 2–3 days may be due to an impurity or to an isomeric state of In^{112}. G. M. Petty

The fission of protoactinium. Niels Bohr and John A. Wheeler. *Phys. Rev.* **56**, 1065–6(1939); cf. *C. A.* **33**, 9115[8].—Estimates are made of the differences between the crit. energy of unstable deformations and the binding energy of the added neutron for the compd. nuclei $_{92}U^{236}$, −0.4 m. e. v.; $_{92}U^{238}$, −1.1 m. e. v.; $_{91}Pa^{232}$, −0.1 m. e. v.; $_{92}U^{230}$, −0.7 m. e. v.; $_{90}Th^{232}$, −1.7 m. e. v.; $_{90}Io^{231}$, −1.2 m. e. v. Fission is produced more easily in protoactinium than in Th, but less easily than in U^{235}. G. M. Petty

Division of uranium nuclei under the action of neutrons and the problem of the existence of transuraniums. V. G. Khlopin, M. A. Pasvik-Khlopina and N. F. Volkov. *Compt. rend. acad. sci. U. R. S. S.* **24**, 118–21(1939)(in English).—Thin layers of U_3O_8 and of Na uranate were bombarded up to 36 hrs. with neutrons with an intensity equal to that of 30 curies of Rn + Be. The bombarded compd. and the recoil atoms were sepd. chemically. The activities of PtS ppts. from U and from recoil atoms are compared. These curves indicate the presence of transuranic elements. Differences between these exptl. procedures and results and those of Meitner and Frisch (*C. A.* **32**, 4869[6]) and of Bretscher and Cook (*C. A.* **32**, 4869[6]) are explained. G. M. Petty

Radioactive gases evolved in uranium fission. L. Wertenstein. *Nature* **144**, 1045–6(1939).—The gases were passed through 2 Geiger-Müller counters, with various time lags between them. Periods of 30 sec. and of 4 min. were detected. G. M. Petty

Study of uranium and thorium fission produced by fast neutrons of nearly homogeneous energy. R. Ladenburg, M. H. Kanner, H. Barschall and C. C. Van Voorhis. *Phys. Rev.* **56**, 168–70(1939).—The effective cross sections of the U and Th fission for neutrons of 2.4-m. e. v. are found to be 5×10^{-26} sq. cm. and 1×10^{-25} sq. cm. (±25%). The ratio of the cross sections for Th and U fission is const. to within 10% for neutrons of 2.1, 2.4, 2.9 and 3.1 m. e. v. av. energy. H. C. Thomas

The nonexistence of transuranic elements. Louis A. Turner. *Phys. Rev.* **57**, 157(1940).—A theoretical discussion. G. M. Petty

Artificial radioactive indicators. Charles Rosenblum and John F. Flagg. *J. Franklin Inst.* **228**, 471–94, 623–48(1939).—A review. The chem. applications which involve the use of active halogen, P, S, Mn, As, and Au are summarized. More extensive investigations of the mechanism and velocity of certain reactions and the botanical and biol. uses of indicators are included. 97 references. M. Farnsworth

The effect of pH on the precipitation and concentration of some radioelements. Maurice Bachelet. *Ann. chim.* **12**, 348–415(1939).—Fractional pptn. of hydroxides controlled by the pH of the soln. is used for sepg. radioactive substances. The carrying down of U X with a Fe(OH)$_3$ ppt. in $UO_2(NO_3)_2$ soln., the concn. of Act and the extn. of Rd-Act in solns. of La and Act, and the concn. of Pa in salts of Zr and Pa are studied. Other insol. salts are also used, particularly the phosphates. The pptn. of $UO_2(HPO_4)$ can be used to fractionate U and U X. Adsorption plays a role in the carrying down of U X by the ferric ppt. in the presence of alkali carbonates. The adsorption of Rd-Act on La and the adsorption of salts of La and Act by $BaSO_4$ are also investigated. M. Farnsworth

Radioactive nodules from Devonshire, England. Max Perutz. *Mineralog. petrog. Mitt.* **51**, 141–61(1939).—Globular concretions surrounded by bleached haloes were found in Permian beds west of Budleigh Salterton, Devon. In their interior a light, sandy matrix is impregnated by a dark hard material in radial and concentric sheets. Contact photographs of a plane section show a distribution of radioactive material closely connected with the structure of the black impregnation. The radioactive substance was centered in a thin amorphous film of a complex U vanadate at the boundary between the dark and the light portions of the nodules. Complete chem. analyses of the light and dark parts are given. The total proportion of the radioactive elements present corresponds to 0.3%–0.5% U or 10^{-7}% Ra. It is suggested that the Rn produced in the nodules diffusing from their surface might be responsible for the formation of the bleached haloes. J. F. Schairer

A quantitative study of pleochroic haloes. IV. New types of haloes. G. H. Henderson and F. W. Sparks.

Proc. Roy. Soc. (London) **A173**, 238–49(1939); cf. *C. A.* 28, 5753[6,7]; 31, 2090[7].—Four types of haloes, provisionally designated as A, B, C and D, are described, 3 of them for the first time. These haloes have 1, 2, 3 and 1 ring, respectively. Measurements of ring radii are given and are shown to be in fair agreement with the ranges of the α-particles from known elements of the U family. **V. Genesis of haloes.** G. H. Henderson. *Ibid.* 250–64.—The most probable parent of halo A is Ra F, of B Ra B or Ra C of C, Ra A, and of D Ra. All of these have lives which are exceedingly short on a geol. time scale. A hydrothermal genesis of these extinct haloes is postulated. M. Farnsworth 1

Theory of the isotope separation process of Clusius and Dickel. I. Ludwig Waldmann. *Z. Physik* **114**, 53–81 (1939); cf. *C. A.* **33**, 6672[6].—Math. The combination of convection, thermo-diffusion and ordinary diffusion is considered. The equations are solved for a plane arrangement. The equil. sepn. efficiency is obtained under simplifying assumptions and also the time of establishment of a steady state with and without gas flow. E. J. R. 2

Diffraction of x-rays by liquid and plastic sulfur. Newell S. Gingrich. *J. Chem. Phys.* **8**, 29–32(1940).—X-ray diffraction patterns of plastic S (at room temp.) and of liquid S (124–340°) were obtained. The position of the main peak ($(\sin\theta)/\lambda$) is 0.138–0.140 at 124–157°, 0.125–0.127 at 166–225° and 0.120 at 340°. At. distribution curves for plastic S and for liquid S at 124°, 166°, 175°, 225°, and 340° are all similar. The nearest neighbors are at 2.08 A. in plastic S and 2.07 A. in liquid S (124–340°). The no. of nearest neighbors is 2.0 for plastic S and 1.7 for liquid S. G. M. Petty 3

X-ray study of some meteoric irons. E. A. Owen and B. D. Burns. *Phil. Mag.* **28**, 497–519(1939).—X-ray diffraction patterns were obtained for 24 meteoric irons with Ni content up to 25.6%. These samples resembled artificially prepd. Fe-Ni alloys in their reaction to heat treatment. The parameter of the α-phase is very const. from one meteorite to another, but the γ parameter shows pronounced variations. This fact is explained in terms of the equil. diagram for Fe-Ni alloys. E. J. Rosenbaum 4

Tables of ultimate lines. Adolfo T. Williams. *Anales asoc. quím. argentina* **27**, 178–219(1939); cf. *C. A.* **33**, 5844.—A table of ultimate rays is arranged in order of decreasing wave lengths. For each ray there are given: emitting atom and its ionization state, wave length, intensity in the arc, in the spark or Geissler tube, and ray of the same atom most often found. There is a Grämont classification and ultimate rays emitted by thermal sources and by Geissler tube. Most of the ultimate rays are found in the region between 5000 and 1850 A., which is the easiest to photograph. There were found 1.9 rays per A. E. M. Symmes 5

Hydrogen showers in the auroral region. L. Vegard. *Nature* **144**, 1089–90(1939).—Two strong H lines were recorded in auroral spectrophotograms taken October 18, 1939. H lines are usually absent from the auroral spectrum. The occurrence of strong H lines is due to showers of H or to a kind of "H radiation" occasionally coming from the sun. The H combines with O, and the H_2O condenses, forming luminous night clouds. G. M. P. 6

Origin of the λ4932 emission in the spectra of novae. A. B. Wyse. *Nature* **144**, 1090(1939).—This line in nebulae is probably due to the $^1P_0 - {}^1D$ transition of O (III); in novae it is probably due to N. G. M. Petty 7

The structure of the solar spectrum between 400 and 600 mμ. Heinz Reiner. *Gerlands Beitr. Geophys.* **55**, 234–48 (1939).—An app. is described for the detn. of the extra-terrestrial energy spectrum. The absorption bands in the chromosphere have a strong radial distribution. J. F. Schairer 8

Atmospheric absorption of infrared solar radiation at the Lowell Observatory. II. The spectral interval: 5.5–8 μ. Arthur Adel and C. O. Lampland. *Astrophys. J.* **91**, 1–7(1940); cf. *C. A.* **33**, 2410[8].—Daily fluctuations and great seasonal variations of intensity occur in the infrared portion of the absorption spectrum of the earth's atm. between 5.5 and 8 μ. When the H_2O vapor in the atm. falls below 3 or 4 mm. of liquid equiv. a small amt. of solar energy near 6.3 μ penetrates the entire column of air owing to the gap in the doublet structure of the H_2O absorption band at this point. C. C. Kiess 9

The physical significance of the *M* − *S* differentiation. Karl Wurm. *Astrophys. J.* **91**, 103–12(1940).—Stars of class *M* are distinguished from class *S* stars by the greater strength of the TiO bands in the former and the greater strength of the ZrO bands in the latter. Since Ti is from 10 to 100 times more abundant in stellar spectra than Zr, the enhancement of the ZrO bands in *S* stars is shown to be due to their considerably lower atm. densities as compared with *M* stars of the same temp. The evidence indicates that the *S* stars are supergiants. C. C. Kiess 10

Excitation of the green auroral line of oxygen. K. G. Emeleus, R. H. Sloane and Eliza B. Cathcart. *Proc. Phys. Soc.* (London) **51**, 978–88(1939).—The exptl. conditions favorable for the emission of the green auroral line of O in discharges through mixts. of O and A were studied. It is found that the partial pressure of the O may be varied from a trace to several percent, but that the optimum value for the total gas pressure is a few mm. It is important that in the discharge there be a region of low ionization such as the aureole that surrounds the core in the constricted pos. column and that in this region there occur collisions of sufficient force between metastable A atoms and normal O_2 mols. to dissociate the mols. and raise the resultant O atoms to the ^1S state. C. C. K. 11

The quantal theory of continuous absorption of radiation by various atoms in their ground states. I. The atoms from boron to neon. D. R. Bates. *Monthly Notices Roy. Astron. Soc.* **100**, 25–9(1939).—A method of calcn., based on the wave mechanics, is used to derive the continuous absorption coeffs. of the unexcited atoms B, C, N, O, F and Ne, over a wide frequency range. Not only is the magnitude of the coeffs. given, but also their correct variations with frequency. These are illustrated graphically for each element. C. C. Kiess 12

The spectrum of 25 Orionis, 1933–39. Helen W. Dodson. *Astrophys. J.* **91**, 126–8(1940).—The behavior of the H emission in the spectrum of this star is described. C. C. Kiess 13

Stark effect and damping factor in the Fraunhofer spectrum. C. W. Allen. *Monthly Notices Roy. Astron. Soc.* **100**, 4–9(1939).—The equiv. widths of some Fe lines in the sun's spectrum and the intensities of the same lines emitted by an arc were measured to det. the curves of growth for these lines. A comparison of the damping factor given by these curves with the Stark effect for the lines by Panter and Foster (*C. A.* **31**, 8371[4]) shows a linear relationship that leads to a value of 14 dynes/sq. cm. for the pressure in the sun's reversing layer exerted by 1.8×10^{13} electrons per cc. C. C. Kiess 14

Photometry of the solar *D* lines. C. W. Allen. *Monthly Notices Roy. Astron. Soc.* **100**, 10–13(1939).—From new photometric measurements of the *D* lines of Na in the sun's spectrum their profiles have been redetd., in light both from the limb and from the center of the sun's disk. Both lines have central intensities of about 7%, but their equiv. widths are 560 and 770 mA., resp., for D_1 and D_2 in light from the center. The Ca^+ lines 8498, 8542 and 8662 A. were found to have central intensities of 35, 26 and 28%, resp. C. C. Kiess 15

CH bands in comet spectra. J. Dufay. *Astrophys. J.* **91**, 91–102(1940).—The wave lengths and their intensities observed in the band structure near 4300 A. in low-dispersion spectra of some comets are in close agreement with those calcd. for the $A^2\Delta \rightarrow X^2\Pi$ band of CH, this fact verifies it as a constituent of these objects. Addnl. though not as reliable evidence is supplied by the $B^2\Sigma \rightarrow X^2\Pi$ band near 3900 A. C. C. Kiess 16

Observation of the spectrum of Ne V. Fred W. Paul. *Phys. Rev.* **56**, 1067(1939).—The Ne lines 572.38, 572.12, 569.84, 568.45, 483.00, 481.30 and 480.38 (all ±0.05 A.) were observed; transitions are assigned. G. M. Petty 17

Positive column of the nitrogen arc at atmospheric pressure. Edward S. Lamar, Albert M. Stone and Karl T. Compton. *Phys. Rev.* **55**, 1235–44(1939); cf. *C. A.* **31**, 18

5633⁶.—A theory of the pos. column in an arc is developed, from which good values of N arc parameters are calcd. Power generation per unit vol., electron concn. and the power loss are calcd. The theory applies only to low-current arcs in ordinary space or to arcs below 30 amperes in gravity-free space. Equating power generation and power loss leads, eventually, to an arc equation of the Ayrton type. The inclusion of convection in a more complete theory is discussed. The departure from the above simplified theory, for arcs of large currents, is qualitatively of the type to be expected from the influence of convection. These results show that the mechanism of the pos. column of arcs is now understood. G. M. Petty

Lecture demonstration of resonance radiation of sodium. R. W. Wood. *Phys. Rev.* **56**, 1172–3(1939). G. M. Petty

New terms in iron I, II and III and additional far ultraviolet standards. Louis C. Green. *Phys. Rev.* **55**, 1209–17(1939).—The Fe spectrum excited in the Schüler discharge in He and Ne and the Fe arc and spark in N were studied from λ 2300 to λ 600. New terms were identified in Fe I, II and III, and a no. of unclassified levels were found in Fe II. Lists of all the lines identified from new or previously known levels are given; these include a no. of lines from λ 2225 to λ 1550, the wave lengths of which can be detd. with sufficient accuracy that they will be useful as standards. G. M. Petty

Zeeman effect in the second and third spectra of xenon. Curtis J. Humphreys, Wm. F. Meggers and T. L. de Bruin. *J. Research Natl. Bur. Standards* **23**, 683-99 (1939) (Research Paper No. 1264).—The Zeeman effect in Xe II and Xe III spectra was observed at "Physica" in Amsterdam and at the National Bureau of Standards. The light source in the first-named lab. was a Back lamp consisting of a spark between metal electrodes surrounded by Xe gas, whereas Xe Geissler tubes placed transversely between the poles of a magnet were used in the 2nd. Measurable patterns were obtained for 130 Xe II and for 62 Xe III lines. From these patterns the g values of 61 Xe II and 34 Xe III levels were calcd. Most of the patterns are only partially resolved but by using formulas for unresolved patterns to set up observational equations adjusted by the method of least squares, fairly consistent g values were derived. The g-sum rule was tested where possible, and was found to be obeyed by 2 different electron configurations of Xe^+. Observed g-values depart considerably from those given by the Landé formula in most instances, indicating a vector coupling scheme intermediate between LS and Jj for both Xe^+ and Xe^{++}. W. F. Meggers

Nuclear magnetic moments of the boron isotopes. S. Millman, P. Kusch and I. I. Rabi. *Phys. Rev.* **56**, 165–7 (1939).—The nuclear Landé g values of ${}_5B^{10}$ and ${}_5B^{11}$ have been measured by means of the mol.-beam magnetic-resonance method with the alkali tetraborates and metaborates. The values, in units of $e/2Mc$, 0.597 ± 0.003 and 1.788 ± 0.005 are assigned to B^{10} and B^{11}, resp. Assuming nuclear spins of 1 and 3/2 for B^{10} and B^{11}, resp., the corresponding magnetic moments are 0.597 ± 0.003 and 2.682 ± 0.008 nuclear magnetons. H. C. Thomas

Nuclear magnetic moments of N^{14}, Na^{23}, K^{39} and Cs^{133}. P. Kusch, S. Millman and I. I. Rabi. *Phys. Rev.* **55**, 1176 81(1939).—Nuclear gyromagnetic ratios of N^{14}, Na^{23}, K^{39} and Cs^{133} were measured by the mol.-beam magnetic-resonance method. The values are, resp., 0.402, 2.216, 0.391, and 2.572 nuclear magnetons. The shape of the resonance curve in some cases indicates a type of interaction of the nucleus with the rest of the mol. which may arise from the nuclear elec. quadripole moment. Magnetic moments calcd. from the observed hyperfine splitting of at. energy states, using the Goudsmit, Fermi-Segre formula (*C. A.* **27**, 3139, 4724) agree well with these results. G. M. Petty

Molecular spectra. Frank D. Carvin. *Newark Eng. Notes* **2**, No. 5, 5–7(1939).—A discussion of the results of the application of quantum mechanics to the problems of the spectra of mols. including the exptl. evidence of mol. spectra and an attempt to fit a math. explanation to this evidence. Leopold Scheflan

Intensity in spectra of diatomic molecules. V. Kondrat'ev. *J. Exptl. Theoret. Phys.* (U. S. S. R.) **7**, 477–82 (1937); *Chem. Zentr.* **1938, I**, 828.—The formula used by Hutchisson (cf. *C. A.* **24**, 5624) for the calcn. of the relative intensities of the bands in electron spectra of sym. diatomic mols. is also useful for the calcn. of the intensities in the spectra of asym. mols. when the bands arise through the combination of lower vibration levels. With OH and NO spectra as examples, it is shown that the formula mentioned gives a qualitatively correct distribution of intensity in these spectra. M. G. Moore

The excitation conditions of nitrogen spectra in the high atmosphere. Jean Cabannes and Rose Aynard. *J. phys. radium* **10**, 455–8(1939); cf. *C. A.* **33**, 9136⁶. W. F. Meggers

Temperature parameters from negative bands of nitrogen under excitation by electron impact. O. S. Duffendack and Kuang-Tseng Chao. *Phys. Rev.* **56**, 176–84 (1939).—In a field-free space, direct temp. detns. along the axis of a N discharge tube agree with results calcd. from measurements on the intensity distribution of the neg. bands of N. A theoretical heat conduction formula gives calcd. values in agreement with expt. The variation of temp. with gas pressure is accounted for by change in thermal cond. The temp. is independent of discharge potential from 40 to 800 volts. In a low-voltage arc the temp. is found to depend on the potential. In a cold-cathode glow discharge the temp. is found to be higher near the cathode-fall space. H. C. Thomas

In the shift of intensity in N_2^+ bands excited in helium and neon. Tosio Takamine, Taro Suga and Yosio Tanaka. *Sci. Papers Inst. Phys. Chem Research* (Tokyo) **36**, 437–48(1939).—A glass discharge tube contg. He or Ne at a pressure of 18 mm. Hg and N_2 at about 0.2 mm. Hg was excited with a condensed discharge and studied with a 1-m. grazing-incidence vacuum spectrograph with dispersion of 6 A./mm. A remarkable change in the distribution of intensity in the 2nd neg. band of N_2^+ is observed as the diluent gas is changed from He to Ne. In He the strongest band is at 1846.3 A., but in Ne it is at 1851.7 A. An explanation, based on sharp resonance between noble-gas ions and N_2^+ ions excited to certain levels, is tentatively outlined. W. F. Meggers

Band spectrum of indium hydride. B. Grundström. *Z. Physik* **113**, 721–9(1939).—The term schemes for the ground state $^1\Sigma$ and the excited states $^1\Pi$ and $^1\Sigma^*$ are given. The bands show perturbations as well as predissocn. The value of ν_0 of the 0,0 band of the $^1\Pi$–$^1\Sigma$ system is 16,905.00 cm.$^{-1}$; for the $^1\Sigma^*$–$^1\Sigma$ system, 16,259.64 cm.$^{-1}$. The types of predissocn. found are discussed. E. J. R.

A reinvestigation of the ultraviolet band system of carbon monoselenide. R. F. Barrow. *Proc. Phys. Soc* (London) **51**, 989–91(1939).—The ultraviolet CSe bands extending from 2760 to 3053 A. have been reobserved with higher dispersion than that heretofore employed. Twelve band heads shaded toward the red have now been measured and are well represented by the formula: $\nu = 35238 + (835.7u' - 2.2u'^2) - (1036.0u'' - 4.8u''^2) - 1.3u'u''$, where $u = v + 1/2$. The dissocn. energy of the ground state is 6.8 v. C. C. Kiess

Absorption spectrum of single-crystal ZnS phosphors. Charles J. Brasefield. *Phys. Rev.* **57**, 162(1940).—A wave length–transmission diagram is given. Absorption is partial for wave lengths less than 4250 A. and is complete for wave lengths less than 3650 A. G. M. Petty

Continuous absorption of N_2O. H. Sponer and L. G. Bonner. *J. Chem. Phys.* **8**, 33–7(1940).—The absorption of N_2O in the long-wave region of the near ultraviolet was reinvestigated with an absorption tube 105 feet long. The absorption in this region is extended and is resolved into several components. Twelve dissocn. processes are considered. G. M. Petty

The absorption coefficient of nitrogen dioxide in the visible spectrum. J. K. Dixon. *J. Chem. Phys.* **8**, 157–60(1940).—At 4850 A., Beer's law is obeyed from 0 to 70 mm. Hg. The absorption curve (4000–7000 A.) is sinus-

pidal, adjacent max. and min. differing by about 10%. [illegible] 773.4, 5 (broad); 1062.6, 3 (diffuse); 1204.6, 4; 1305.7, 5; 1401.8, 7 (broad). The max. are sepd. by 700 ± 100 cm.$^{-1}$. They are due to groups of excited levels which are uniformly sepd. G. M. Petty

The absorption in the middle ultraviolet of certain phenylhydrazides. D. Biquard and P. Grammaticakis. *Bull. soc. chim.* **6**, 1599–1615(1939).—The study of absorption in the middle ultraviolet (3700–2200 A.) of acidulated derivs. of phenylhydrazine shows that these products exist, in alc. soln., and at ordinary temp., principally under the form of true phenylhydrazide. The modification of the absorption spectrum of phenylhydrazine provoked by the substitution of one or more hydrogens by various aliphatic or aromatic acid groups shows that: (1) The substitution of a hydrogen in position α profoundly modifies the form and position of the absorption curve of phenylhydrazine, (2) the substitution of a hydrogen in β modifies the absorption only slightly, (3) the substitution of hydrogens in α and β profoundly modifies the absorption spectrum of phenylhydrazine, the absorption of the $\alpha\beta$ substituted deriv. being conditioned by the substituant in α. The methods of prepn. and purification are given for 21 phenylhydrazides which were studied. W. F. Meggers

The absorption of water vapor and carbon dioxide with reference to pressure and temperature dependence. Fritz Schnaidt. *Gerlands Beitr. Geophys.* **54**, 203–34 (1939).—Normal absorption, effective vapor pressure, line absorption and "rational" CO_2-spectrum are discussed. J. F. Schairer

Infrared and Raman spectra of polyatomic molecules. X. C_2D_2, C_2DH and C_2H_2. Fred Stitt. *J. Chem. Phys.* **8**, 56–9(1940); cf. *C. A.* **33**, 5291[2].—The infrared spectra of these compds. are reported from 450 to 4000 cm.$^{-1}$. All but 2 of 30 observed bands are assigned as fundamentals, first and second overtones, and one-one combination or difference bands. Most of the bands of these types which are infrared-active according to the selection rules are either observed or occur in a region where they may be masked by the presence of superimposed bands. **XI. Dimethyl sulfide.** R. Fonteyne. *Ibid.* 60–2.—The infrared spectrum of gaseous Me_2S (1.6–2.6 μ) and the Raman spectrum of liquid Me_2S (280–3000 cm.$^{-1}$) are reported. A tentative vibrational analysis is given. G. M. Petty

Infrared absorption spectra of AsH_3, AsD_3 and PD_3. E. Lee and C. K. Wu. *Trans. Faraday Soc.* **35**, 1366–73 (1939).—The infrared absorption frequencies were observed for AsH_3 to be 2122, 2185, 906 and 1005 cm.$^{-1}$; AsD_3: 1534, 660 and 714 cm.$^{-1}$; PD_3: 1694, 730 and 806 cm.$^{-1}$. The 4.7-μ (fundamental, ν_1) band of AsH_3 was detd. under high dispersion and a graph is presented. A value of 7.43×10^{-40} g. cm.^{2} is deduced for the A moment of inertia. The rotational structure of the band is complex, probably owing to overlapping of ν_2 and the interaction between the rotation levels of ν_1 and ν_2. The transmission of PD_3 near 760 cm.$^{-1}$ is given under high dispersion. The valency force field gives a good representation of the actual intramol. forces present. V. R. D.

Coriolis perturbations in the spectra of silane and germane. George M. Murphy. *J. Chem. Phys.* **8**, 71–8 (1940).—A Coriolis perturbation on the rotational structure of the fundamental frequency, ν_4, has been computed for silane and germane. Matrix elements of the Coriolis operator, A, for the lines $P(9)$, $P(10)$ and $Q(10)$ have also been obtained. The envelope of the resulting absorption curve has been compared with the exptl. curve and good agreement is found. The most striking difference in the two spectra is that in the case of silane, the Q branch degrades toward lower frequencies and in germane, toward higher frequencies. This is due to the relative position of the infrared inactive frequency, ν_2, to which the perturbation is due. G. M. Petty

Raman effect of fluorochlorobromomethane. Geo. Glockler and G. R. Leader. *J. Chem. Phys.* **8**, 125 (1940).—Raman lines (cm.$^{-1}$) and their relative intensities are reported for CHFClBr (d., 1.994; b_{734}, 38–39°): 225.0, 10; 313.0, 9; 425.0, 9; 648.9, 6; 658.7, 10; [illegible] 8, 7 (broad). G. M. Petty

The [illegible] structure of the hydrazoic acid bands in the photographic infrared. Eugene H. Eyster. *J. Chem. Phys.* **8**, 135–42(1940).—The third and fourth harmonics of the N–H stretching frequency in N_3H, at 9548.91 and 12,412.19 cm.$^{-1}$, resp., were studied. The rotational structure was resolved and analyzed, yielding the rotational consts. in both the ground and the excited states. The mol. parameters are: N_1–H, 1.012 A.; N_1–N_2, 1.241 A.; N_2–N_3, 1.128 A.; ΔHN_1N_2, 110°52′. G. M. Petty

Normal vibrations of chains of similar and similarly situated dynamical systems and the infrared spectrum of undecane. S. E. Whitcomb, H. H. Nielsen and L. H. Thomas. *J. Chem. Phys.* **8**, 143–52(1940).—The normal modes of vibration of chain mols. fall into 2 classes: end vibrations, in which the amplitude falls off exponentially from the ends toward the middle, and chain vibrations in which it varies harmonically as in a standing wave. The theory is developed, and calcns. are made for n-$C_{11}H_{24}$. The infrared spectrum of n-$C_{11}H_{24}$ was measured from 1 to 15 μ. Theory and expt. are in excellent agreement: 28 of 31 observed bands were accounted for as fundamentals, harmonics, or simple combination frequencies. G. M. Petty

Spectroscopic evidence for hydrogen bonds: comparison of proton-attracting properties of liquids. II. Walter Gordy and Spencer C. Stanford. *J. Chem. Phys.* **8**, 170–7 (1940); cf. *C. A.* **33**, 2396[8].—*m*-MeC_6H_4CHO, PhCH:CHCHO, furfural, Me_2C:$CHCH_2CMe$:CHCHO, *n*-C_6H_{13}-CHO, Et_2CHCHO, iso-BuCOMe, $(iso\text{-}Bu)_2CO$, MeCO-Am, Me_2C:$CHCOMe$, PhCOMe, *p*-MeC_6H_4COMe, cyclohexanone, fenchone, HCOO(iso-Am), $ClCH_2COOEt$, $Ac(CH_2)_3Br$, AcPh, furfuryl acetate, PhCOOMe, $PhCOOCH_2Ph$, *o*-$C_6H_4(COOBu)_2$, $(-COOEt)_2$, $CO(OEt)_2$, $PO(OBu)_3$, EtOBu, $(CH_2ClCH_2)_2O$, $(PhCH_2)_2O$, PhOEt, OCH_2CHCH_2Cl, Am_2NH, Am_3N, $PhCH_2NH_2$, $(PhCH_2)_2NH$, $PhNH_2$, *o*-$ClC_6H_4NH_2$, *m*-$ClC_6H_4NH_2$, $PhNMe_2$, *o*-$MeC_6H_4NH_2$, *o*-$H_2NC_6H_4COOMe$ and pyrrole are ranked according to their proton-attracting power by comparing the strength of the H bonds they form with MeOD. The perturbation caused in the OD vibrational band is taken as a measure of the strength of the D bridge. The order of proton-attracting power is ester < aldehyde and ketone < ether < amine. The strength of the D bond (formed with MeOD) bears a close relation to the basicity of the solvent, its solubilities for other proton-donor solutes, and to its reactivity with other compds. There is no correlation between solvent dipole moment and the strength of the bonds formed with MeOD. G. M. Petty

Absorption spectra of sugars in the near infrared. E. S. Barr and C. H. Chrisman, Jr. *J. Chem. Phys.* **8**, 51–5 (1940).—The infrared absorption spectra of aq. solns. of *l*-rhamnose, β-glucose, *d*-xylose, *d*-levulose, *d*-mannose, *d*-galactose, *d*- and *l*-arabinose, *d*-glucose, sucrose, maltose, *d*-lactose, and β-lactose were observed. A special technique of evapn. was used in the prepn. of samples, so as to minimize the effect of the solvent on the transmission curves. All 13 sugars gave very similar spectra; band locations were nearly identical, although there was some variation in intensities. Bands not previously reported were found at 2.16 and 2.35 μ, and the intense absorption in the region of 3.3 μ was partially resolved into component bands. G. M. Petty

Infrared O–H band and association. J. Errera, R. Gaspart and H. Sack. *J. Chem. Phys.* **8**, 63–71(1940).—Infrared absorption spectra in the 3-μ region were studied for alc. in CCl_4 and CS_2; for ternary mixts. alc. + pyridine + CCl_4 and alc. + Me_2CO + CCl_4; and for HDO in D_2O, dioxane and pyridine. (1) Alc. is completely dissocd. (in CCl_4 and CS_2) only at concns. below 0.1 vol. %. (2) In the mechanism of the assocn. of alc., at least 2 steps are distinguished: formation of double mols. and of polymol. complexes. The latter are very sensitive to an increase of temp. of 30–40°. (3) Alc. forms addn. compds. with mols. contg. O or N and these addn. compds. still exist after diln. in an inert solvent. (4) The O-H vibration gives rise to the same band in pure water and in a

soln. of HDO in D_2O. (5) For HDO dissolved in a solvent the mols. of which contain O, the doubling of the band of the addn. compd. H_2O + solvent disappears.
G. M. Petty

The infrared absorption spectrum of methylphenylacetylene. M. J. Murray and Forrest F. Cleveland. *J. Chem. Phys.* **8**, 133–4(1940).—The infrared spectrum of MeC:CPh (500–2300 cm.$^{-1}$) is compared with the Raman spectrum. The results do not permit the assignment of the fundamental whose overtone is responsible for the resonance splitting of the frequency near 2230 cm.$^{-1}$. 2
G. M. Petty

Interpretation of the Raman spectra and infrared spectra of the halogen derivatives of methane. H. Volkringer, J. Lecomte and A. Tchakirian. *J. Chem. Phys.* **8**, 126 (1940); cf. *C. A.* **31**, 6556[2]; **32**, 4878[7].—The $\delta_{12,345}$ and ν_{1234} Raman and infrared frequencies of CF_2Cl_2, $CFCl_3$, CCl_4, CCl_3Br, CCl_2Br_2, $CClBr_3$ and CBr_4 are compared. 3
G. M. Petty

Raman spectra of simple ethers. Forrest F. Cleveland, M. J. Murray, Herschel H. Haney and Julia Shackelford. *J. Chem. Phys.* **8**, 153–6(1940).—Displacements, intensities and depolarization factors are listed for the main lines of Et_2O, Pr_2O, $(iso\text{-}Pr)_2O$, Bu_2O, $(iso\text{-}Bu)_2O$, Am_2O, $(iso\text{-}Am)_2O$. All frequencies near 2900 cm.$^{-1}$ are polarized except the one near 2970 cm.$^{-1}$, which is highly depolarized. 4
G. M. Petty

Internal rotation of ethane, propane and butane derivatives by the Raman effect. Sizuo Nakamura. *J. Chem. Soc. Japan* **60**, 1010–19(1939).—The Raman spectra of 1-chloropropane, 1-bromopropane, 1-iodopropane, 1-bromobutane, ethylene glycol, ethylene chlorohydrin, ethylene bromohydrin and ethylene iodohydrin were studied in the solid and in the liquid states. These results seem to show that 2 mol. forms exist in the liquid, while in the solid one of them vanishes. The possible mol. forms are discussed. 5
T. Katsurai

Raman spectroscopic investigations. XV. Constitution of orthophosphoric acid and its salts. A. Simon and G. Schulze. *Z. anorg. allgem. Chem.* **242**, 313–68(1939); cf. *C. A.* **33**, 5741[6].—The prepn. and properties of anhyd. H_3PO_4 are described. Also D_3PO_4 (83%), $POCl_3$, $PSCl_3$, $PO(OMe)_3$, $PS(OMe)_3$, and the primary and tertiary orthophosphates of the alkali metals were prepd. The Raman spectra were studied at various concns. and exposure times, with prism spectrographs and Hg 4358 A. It was concluded that 100% H_3PO_4 changes to no new mol. forms on diln., and has a tetrahedral structure, with polar-bound H. The similar symmetry between H_3PO_4 and $H_2PO_4^-$ ion explain the unchanged spectrum obtained on diln., any variation in frequency being due to a superposed action of hydration and dissocn. These conclusions are supported by the character of the spectra of the ester-like substances studied; correspondence between the spectra of H_3PO_4 and its alkali salts; and the variation of the spectrum of the acid when dissolved in EtOAc (but non-appearance of $H_4P_2O_7$). Also, the spectrum of the acid remained unchanged on the addn. of mineral acids. The presence of acidic salts is improbable. Comparative absorption measurements in the ultraviolet, between 100% and dil. H_3PO_4, and its tri-Me ester show differences too small to permit a discussion of the probable mol. forms. The uniformity of the spectra of the primary and tertiary alkali salts shows the lack of influence of these ions on the respective anions. For equimol. concns., the values of the totally symmetric frequency of the $H_2PO_4^-$ ion are equal for all the alkali salts. The lowering of frequency, observed in the spectrum of D_3PO_4, as compared with that of H_3PO_4, falls short of the amount calcd. from the mass ratio. The appearance of a line of higher frequency in D_3PO_4 and K_2DPO_4 cannot be explained. It is proposed that the H bond is somewhat homopolar, and there is given a mechanism for proton migration in H_3PO_4 and its ions, explaining the formation of $H_4P_2O_7$ on melting, and other effects. The energy of the P—O bond, detd. from the Raman spectrum is 138 cal., which is in good agreement with that calcd. from the luminous spectrum (142 cal.). **XVI. Structure of monopersulfuric acid.** A. Simon and G. Kratzsch. *Ibid.* 369–74.—The prepn. of anhyd. H_2SO_5 is described. The Raman spectrum was studied to det. whether the anhyd. acid exists in the pseudo (enol) form, and whether the monobasicity of the acid is due to a S—H bond. The appearance of the OH band shows that the anhyd. acid is a pseudo acid with the H—O bond homopolar (giving $SO_2.O.OH.OH$). No evidence of a S—H bond was detected (which vibration should appear at about 2500 cm.$^{-1}$). The large number of lines shows the mol. to be unsym. 1
John W. Knowlton

Spectroscopic measurements of gaseous CN. I. Dissociation in the electric discharge. John U. White. *J. Chem. Phys.* **8**, 79–90(1940).—Free CN radicals in the gaseous state are formed in the elec. discharge through cyanogen. By the use of a very intense low-pressure spark as a background the 0,0 and 1,1 bands of the $^2\Sigma \rightarrow {}^2\Sigma$ transition of CN have been observed in absorption at short intervals of time after the end of this discharge. The intensities of the lines of the bands were measured by means of microphotometer traces of the spectra and of the characteristic curve of the photographic plate. They were corrected for the incomplete resolution of the spectrograph. Relative concns. of CN were calcd. from the sums of the intensities of the lines. The rate of disappearance of CN after the end of the discharge was found to be the same over a large range of pressure and diln. with A. A mechanism is proposed to account for this. In all cases the disappearance was exponential with a mean half-life of 11 milliseconds. The half-life of the first excited vibration state was 3 milliseconds, during which time about 10,000 collisions occurred. By diln. of the cyanogen in the discharge tube with A until the CN bands were no longer visible the partial pressure of CN could be calcd. on the assumption that near this point all the cyanogen present was observed in the form of CN. The min. detectable pressure of CN was of the order of 2×10^{-6} mm. The abs. f value of the $^2\Sigma \rightarrow {}^2\Sigma$ transition is 0.026 ± 0.006. By using the corresponding abs. absorption coeff. and the observed temp. distribution in a C arc the partial pressure of CN present in an arc is calcd. to be of the order of 10 mm. The app. is described.
G. M. Petty

Quenching and vibrational energy transfer in the fluorescence spectrum of S_2. Eric Durand. *J. Chem. Phys.* **8**, 46–51(1940).—The ultraviolet fluorescence of S_2 was excited by the strong Mg spark lines λλ 2928 and 2937 A. A typical Wood resonance progression was observed with pure S_2 only in the vessel, but the addn. of a few mm. of any of the rare gases caused changes in the fluorescence due to quenching and to the transfer of vibrational and rotational energy. The yields per collision for quenching and for vibrational transfer are of the order of magnitude of unity, and both show the same dependence on the at. wt. of the rare gas added, with a min. in the vicinity of A or Kr. Comparisons are made with the results obtained by other methods. Quenching occurs by the addn. of 2 quanta of vibrational energy to the S_2, followed by disruption due to predissocn.

Fluorescence of biacetyl. G. M. Almy, H. Q. Fuller and G. D. Kinzer. *J. Chem. Phys.* **8**, 37–45(1940).—Ac_2, in the vapor phase or in aq. soln., exhibits a bright green fluorescence when excited with light within its absorption band in the violet and near ultraviolet. The spectrum is the same as is shown in the fluorescence of Me_2CO vapor when excited with λ 3130. The fluorescence spectrum is insensitive to changes in Ac_2 pressure (0.1–50 mm.), temp. (10–100°), exciting wave length (3650–4358 A.) or amount of added O, which quenches the fluorescence strongly. The intensity of fluorescence, measured with photocell and amplifier, is const. in time, with weak excitation. The ratio of intensity of fluorescence to light absorbed is independent of the pressure and the intensity of the fluorescence is linearly proportional to the exciting intensity, at const. pressure. The fluorescence is quenched by O, the intensity falling to one-half at 0.013 mm. O. The Stern-Volmer law (cf. *C. A.* **14**, 2885) is followed over a range of O pressures in which the fluorescence drops to 20% of the intensity without O; at higher pressures the intensity falls more rapidly than expected. The O is

consumed, presumably in the quenching process, and the fluorescence returns to full intensity. From the quenching curve and from an expt. on the diffusion of the excited mols. into shadow the lifetime of the fluorescing mol. is estd. to be about 10^{-8} sec. These results can be understood on the assumption that the Ac_2 mol. emits the fluorescence after excitation and redistribution (spontaneous and through collisions) of the vibrational energy. In the case of Me_2CO the fluorescence builds up gradually from practically zero intensity, as expected if Ac_2 is accumulating; it is excited, not by light, but probably by collisions with excited Me_2CO or with combining radicals. The diffusion expts. can scarcely be reconciled with the assumption that the observed emission in pure Ac_2 is a recombination spectrum. G. M. Petty

Infrared dichroism in iodoform. Yeou Ta. *Compt. rend.* **209**, 990–2(1939).—Examn. of the infrared (λλ 14610–24780) absorption of a well-developed crystal of CHI_3, the space group of which is probably C_{3i}^4 (Nitta, *C. A.* **20**, 1735), shows pleochroism related to the CH link, similar to, but more marked than, that connected with the CH_2 link in pentaerythritol and diketopiperazine (Ellis and Bath, *C. A.* **33**, 9142[2]). C. A. Silberrad

Flame method of spectrochemical analysis. F. Majewsky. *Nature* **144**, 1047(1939).—M. has improved and adapted for routine use Ramage's method of spectrochem. analysis (*C. A.* **23**, 5429; **24**, 5796). About 50 mg. of material is rolled in filter paper, and the roll burned in an oxy-coal-gas flame before a spectrograph. Reproducibility depends on the uniformity of feeding the roll into the flame. This was difficult because the roll burst into flame just outside the oxy-coal-gas flame. This difficulty was overcome by carbonizing the roll before burning it. The heat treatment was combined with exposure to NH_4Cl vapor, to convert the mineral elements to chlorides. The sensitivity was increased 30 times for Ca, the chloride of which is more volatile than the carbonate. The burning time is about 75 sec. The technique gives promising results in a survey of the *mineral status of the leaves of fruit trees*. G. M. Petty

Lattice vibrations of crystals and the corresponding vibrations of their solutions. S. I. Weissman and Simon Freed. *J. Chem. Phys.* **8**, 227–8(1940).—Crystals of hydrated $EuCl_3$ possess structures in their absorption spectrum which are faint but accurate repetitions of the intense patterns arising from electronic transitions in the Eu ions. These repetitions occur on both sides of the intense patterns at intervals which are ascribed to oscillations of the lattice, thermally as well as optically excited oscillations. The spectra of aq. solns. of $EuCl_3$ and also of $Eu(NO_3)_3$ closely parallel the structures in the spectrum of the crystals. In the region where the crystals absorb, the solns. also absorb. The structures in the spectra of the solns. are somewhat more diffuse than the corresponding structures in the spectra of the crystals. Especially is this true for the structures at the intervals corresponding to lattice vibrations. G. M. Petty

Studies on luminescent materials. I. Theory of zinc sulfide copper crystal phosphor. Yasuo Uehara. *Bull. Chem. Soc. Japan* **14**, 539–46(1939).—See *C. A.* **33**, 4522[4]. J. E. D.

Studies on luminescent materials. III. Effect of temperature on the intensity of fluorescence of zinc sulfide crystal phosphor. Yasuo Uehara. *J. Chem. Soc. Japan* **60**, 900–10(1939); cf. *C. A.* **34**, 29[2].—The intensity of fluorescence of ZnS phosphor was measured in the range from room temp. to 450°. The intensity decreases with the rise of temp. The cause of this phenomenon is interpreted from the quantum mech. point of view. T. Katsurai

Magnetic rotatory dispersion and the refractivity of aqueous solutions of nickel sulfate throughout the range 5780 A. to 2482 A.; especially the magnetic rotation in the 3950-A. absorption band. R. W. Roberts and S. F. Adams. *Phil. Mag.* **28**, 601–13(1939); cf. *C. A.* **30**, 2099[4].—Verdet consts. at 22° were detd. for 2 aq. solns. of $NiSO_4$ and n was measured for the same solns. Absorption max. were found at 3950 A. and at 7200 A. The dispersion curve of the magnetic rotation near the 3950-A. band is asymmetric, confirming the suggestion of Gorter (cf. *C. A.* **33**, 3221[3]) that the rotation of the Ni ion is partially of the paramagnetic, temp.-independent type. E. J. Rosenbaum

Exchange reaction of gaseous bromine and hydrogen bromide. Laurence C. Liberatore and Edwin O. Wiig. *J. Chem. Phys.* **8**, 165–70(1940).—The exchange reaction $HBr^* + BrBr \rightleftharpoons HBr + BrBr^*$ (Br^* = Rd-Br) in the gas phase falls just short of attaining equil. in 2 min. This rapid rate of exchange is accounted for by a chain reaction involving Br atoms. G. M. Petty

Photochemical decomposition of ammonia adsorbed on copper sulfate and magnesia crystals. V. Beselovskiĭ. *J. Phys. Chem.* (U. S. S. R.) **13**, 586–92(1939).—Exptl. data are given for the rates of decompn. by Al, Zn, Fe and Cd sparks with various filters. The av. energy for the decompn. of adsorbed NH_3 is 99 Cal. on $CuSO_4$ and 106 Cal. on MgO. The max. are shifted, resp., 51 and 44 Cal. with respect to the gas phase. F. H. Rathmann

High-temperature photolysis of acetaldehyde. David C. Grahame and Gerhard K. Rollefson. *J. Chem. Phys.* **8**, 98–105(1940); cf. *C. A.* **33**, 8502[8].—An investigation of the high-temp. (60–350°) photolysis of AcH vapor gave results differing in certain details from those of previous investigators. The heat of activation for the over-all reaction is 8.6 ± 0.3 kg.-cal.: this leads to a value of 75 kg.-cal. for the energy of the C—C bond in AcH. The reaction between Me radicals is bimol. Relative quantum efficiencies for the production of free radicals in Me_2CO and AcH at elevated temps. were detd. at 2 wave lengths. G. M. Petty

Photochemistry of diiodoacetylene and tetraiodoethylene. John W. Tamblyn and Geo. S. Forbes. *J. Am. Chem. Soc.* **62**, 99–104(1940).—The photoiodination rate of diiodoacetylene (I) in hexane, with careful exclusion of O, was studied quantitatively in red and in blue light. Tetraiodoethylene (II) is found to be formed quantitatively. The equation $-d[I_2]/dt = k\lambda L_0 x\lambda [I_2]([C_2I_2]/(a\lambda + b\lambda[C_2I_2]))$ generalizes the data obtained; L_0 is the incident-light flux; $k\lambda$, $x\lambda$, $a\lambda$ and $b\lambda$ must be evaluated separately for each spectral interval considered. A chain mechanism occurs which varies with the λ of the light employed. A sp. rate const. was obtained. The data on the photolysis of II in hexane by λ 254 mμ indicate that at first one mol. of free I appears for each mol. of II which disappears, and gives a quantum yield of 0.8. A qual. study of the photolysis of I in hexane indicates a complicated process due to the formation of polymeric substances. A. B. Garrett

Oxygen in electric steel. V. T. Braga. *Teoriya Prakt. Met.* **1938**, No. 10, 33–7; *Khim. Referat. Zhur.* **2**, No. 4, 95–6(1939); cf. *C. A.* **34**, 688[8].—The content of O was detd. analytically according to Herty, verified from the diagram of Schenck, the formula of Chipman and from the velocity of C combustion. For optimum results a velocity of C combustion of 0.0085–0.01%/min. at the beginning of the melting period is decreased to 0.004%/min. in the last 20–30 min. and then adjusted to the required content of C at the end of the first period. The velocity of C combustion is decreased by the addn. of CaO and CaF_2 with an increase of the amt. of slag. For a partial sepn. of the metal from FeO at the end of the first period burned Fe ore briquets or ore in large lumps is added to facilitate penetration into the molten metal. A no. of tests showed that it is necessary to keep a well-defined Mn content during melting (≥0.2%) in the basic process and, more so, in the acid process in order to reduce the amt. of the nonmetallic impurities toward the end of the first period. The amt. of O in the metal depends on the percentages of Mn and Si; the data of Kerber and Elsen were verified for exptl. acid melting. The amt. of O in the cast metal varies for the acid process from 0.0062 to 0.0110%; for the basic process from 0.0057 to 0.0103%. The loss of Cr in the slag increases with increase in O content but decreases with increase in Mn and Si contents. W. R. Henn

The construction and functions of the electrolytic chlorine cell. Cölestin Haider. *Z. Elektrochem.* **45**, 795–806 (1939).—The theoretically necessary conditions are discussed for the operation of a cell with 100% Cl_2 + NaOH yield. The velocity of diffusion of NaOH into NaCl solns. at 20°, 36°, and 50° was detd. All the factors which influence the operation of the cell are collected into a scheme showing their relations. The formulas and equations thus derived are simplified to a basic formula introducing the concept of "characteristic cell number." The various data of cell construction are derived from the characteristic no. H. C. Thomas

The gas cell; mechanism of the electrolysis of water; polarization of the cells. N. Vasilesco-Karpen. *Compt. rend.* **209**, 988–90(1939); cf. *C. A.* **34**, 1257[6].—V.-K.'s views are applied to the Grove gas, and the Leclanché cell (dry battery). C. A. Silberrad

Conductometric method of controlling the acidity in the production of electrolytic manganese dioxide. E. Kh. Hel'gren and Yu. A. Larionov. *Zavodskaya Lab.* **8**, 925–31(1939).—An investigation of the elec. cond. of solns. obtained in the electrolytic production of MnO_2 showed that an increase in the concn. of the H_2SO_4 in the soln. is proportional to the ratio of the resistance of the starting soln. to the resistance of the soln. which is being tested. This relationship is not affected by temp. variations. The ratio of resistances was measured by vacuum tube circuit. The results indicate that the arrangement can be used for detg. the increase in the H_2SO_4 concn. in the soln. provided the temp. during the measurements is const. and the starting soln. is used as a standard of comparison. The cell must be cleaned often to remove the MnO_2 ppt. B. Z. Kamich

Practical plating suggestions. Edward Finnic. *Products Finishing* **4**, No. 2, 44(1939).—Recommendations are made for applying nonpitting agents to pitting Ni-plating solns., the removal of scum and dirt from the top of plating solns. by air skimming, and the prevention of contamination by anode rods. Leopold Scheflan

Electrolysis of mixtures of salts of dibasic organic acids (succinic acid, glutaric acid, pyrotartaric acid, ethylmalonic acid) and nitrates. Fr. Fichter and Ernst Bloch. *Helv. Chim. Acta* **22**, 1529–40(1939); cf. *C. A.* **29**, 2094[7], 6150[9]; **30**, 7049[2]; **32**, 2845[9], 5707[5]; **33**, 487[1], 8172[4].—Ethanediol dinitrate (I) and 1,4-butanediol dinitrate are formed on electrolysis of succinate-nitrate mixts. Although the nature of the higher-boiling fractions has not been completely detd., no diethylene glycol was found after reducing sapon. Electrolysis of glutarate-nitrate mixts. gave 1,2-propanediol dinitrate (II), 1,3-propanediol dinitrate (III) and glycerol di(?)nitrate (IV). Electrolysis of Me succinate-nitrate mixts. and of Et malonate-nitrate mixts. gave II and IV. Since alkenes but, at least primarily, no alcs. are formed on the electrolysis of the salts of these dibasic acids, it is believed (cf. F. and Gunst, *C. A.* **34**, 679[9]) that the alkenes are not intermediate products in the formation of the alkyl nitrates. The alkyl nitrates are formed from alcs. and HNO_3 at the anode; only the formation of the nitrates of the higher alkyl homologs presupposes the action of the alkenes, which are added to the alkyl nitrates. The alkenes arising from the salts of the dibasic acids (ethene from succinate, propene from glutarate, Me succinate and Et malonate) give with HNO_3 at the anode I, II and III. The appearance of III (in addn. to II) in the electrolysis of glutarate-nitrate mixts. is attributed to a reaction between nitrate anions and C_3H_6 radicals immediately after the carboxyl groups have been split off (cf. F., *C. A.* **33**, 2815[1]). Dinitrates of higher alkene homologs appear in the electrolysis of the succinate-nitrate mixts., but not in the 3 examples of the C_5 series. Apparently ethene is especially reactive, although ethene is not the only substance adapted to such syntheses (*C. A.* **30**, 5133[1]; **32**, 7830[4]). In the electrolysis of mixts. with nitrates the formation of glycol dinitrates from alkenes and HNO_3 at the anode can occur only with simultaneous oxidation. That oxidation processes can occur at the anode in the electrolysis of these mixts. is shown by the abundant formation of IV from the primary occurring propene, as in the case of the 3 isomeric dicarboxylic acids of the C_5 series: Ruth Berggren

The hydrogen peroxide theory of electrolytic oxidation. S. Glasstone and A. Hickling. *Chem. Rev.* **25**, 407–41 (1939).—The primary postulate of the theory is that the OH radicals produced at the anode by the discharge of OH^- ions, which are always present in aq. solns., immediately combine irreversibly to form H_2O_2. Under most conditions the H_2O_2 is formed, even at relatively low anode potentials, probably as a thin concd. layer over the electrode surface. In the absence of a depolarizer capable of being oxidized, the H_2O_2 decomps. to give O and H_2O, but if a suitable depolarizer is present, it brings about oxidation in its own characteristic manner; this may be accompanied by oxidation due to the nascent O arising from the decompn. of H_2O_2 and possibly by evolution of O. The extent to which oxidation by H_2O_2 takes place will depend on its stability under the conditions of electrolysis, and all factors capable of affecting the decompn. of the H_2O_2 may be expected to have some effect on the electrolytic oxidation. The H_2O_2 formed at the anode can react in at least 5 ways: (1) it may bring about oxidation by accepting electrons from the depolarizer and being reconverted into OH ions; (2) it may bring about apparent reduction of highly oxidized compds. such as MnO_4^-; (3) its reaction with non-ionized org. compds. may result in the introduction of OH groups into their mols.; (4) the H_2O_2 or the active O arising from its decompn. may bring about oxidation of a general nature; (5) if no suitable depolarizer is present, O is evolved. If H_2O_2 is produced anodically, as postulated, then the catalytic effect of the electrode material on its decompn. should be related in some manner to the oxidation efficiency. The exptl. results obtained are in general agreement with those anticipated. G. and H. also discuss, in relation to the theory, the exptl. results obtained in detg. the effect of other factors—such as the catalytic action of certain ions and the effect of acidity, alkalinity, temp., c. d., depolarizer concn., and foreign ions—upon the oxidation efficiency. Louise Kelley

Electrical characteristics of low-pressure discharges. John W. Marden and George Meister *Trans. Illum. Eng. Soc.* (N. Y.) **34**, 1095–1107(1939).—The elec. characteristics of discharges depend collectively on the kind of gas, pressure, tube diam., length, the voltage drop at the electrodes and if Hg is present also to some extent on the temp. or corresponding Hg pressure. The voltage drop at the electrodes depends for a given set of conditions on the electrode construction and method of operation. The gradient (volts/cm. in the discharge path) decreases with increasing tube diam. and with increasing current; but increases with increasing inert gas pressure. In the case of Hg discharges at const. inert gas pressure, the gradient decreases somewhat with increasing pressure of Hg corresponding to an increase in temp. in the region investigated (2 48 microns corresponding to 30 70°). This effect is not appreciable with Kr, but it is large with He. The total lamp voltage, therefore, is the sum of the voltage drop at the electrodes plus the product of gradient multiplied by discharge length. C. G. F.

Coated carbon electrodes for applying fused masses of alloys. F. V. Buryak. *Avtogennoe Delo* **8**, No. 7, 22–7 (1937); *Chem. Zentr.* **1938, I**, 2052.—Expts. are reported for applying fused masses of Fe-Mn and Fe-Cr alloys to steel by means of C electrodes coated with these alloys. M. G. Moore

Chemical studies on the electrodeless ring discharge. I. The discharge in water vapor. Nobuzi Sasaki and Eiiti Ohara. *J. Chem. Soc. Japan* **60**, 1161–9(1939); cf. Rodebush and Wahl, *C. A.* **28**, 412⁶.—The results of R. and W. were verified and the working conditions studied in detail. **II. Discharge in water vapor.** Eiiti Ohara. *Ibid.* 1170–2. T. Katsurai

Selenium rectifiers. A. H. Cameron. *Elec. Engr. and Merchandiser* (Australia) **16**, 261–6(1939).—The semiconducting layer of the Se rectifier consists of Se. In the manuf. of the disks, a coating of Se (0.05 mm. thick) is applied to one side of a roughened Fe disk (the back electrode). A very thin Se coating is necessary to keep the internal losses down and to maintain constancy in rectifying characteristics. The final step is to cover the front face of the Se with a thin sprayed coating of one or the other metal. The normal working potential which may be applied to a Se rectifier disk is 18 v., a. c. The c. d. for continuous working in a forward direction is 50 ma./sq. cm. Under full load the effective ratio is 50:1. Owing to internal heating the current loading is limited. The rectifier's temp. should not exceed 35°. Artificial cooling is frequently resorted to. Among the units described and illustrated is a 1000-amp. 6-volt unit for electroplating plants and a high-voltage unit of 33,000 v., d. c., 30 ma. C. G. F.

Methods of measuring atmospheric electricity. I. The nature of the atmospheric electrical field and the vertical currents. H. Israël. *Gerlands Beitr. Geophys.* **55**, 314–33(1939).—A "potential-variograph" is described for measuring potential gradient in the vertical current. J. F. Schairer

***The hypothetical electrical field of the earth.** Adolf Schmidt. *Gerlands Beitr. Geophys.* **55**, 292–302(1939).—The history of the vertical elec. currents, derived from geomagnetic observations, is briefly discussed. The assumption that these currents are not real but only a consequence of remaining errors in the observations, is supported by a detailed comparison of these currents for the epochs 1885 and 1922. The nature of the errors and means for their elimination are discussed. J. F. S.

Determination of the piezo-electric effect. P. K. Hermann. *A E G Mitt.* **1939**, 497–502.—The piezo-elec. behavior of a crystal involves 18 measurements, comprising the 6 voltage components. Even though the conversion efficiency of applied mech. pressure into elec. energy is very small (about 1% for a quartz crystal) nevertheless an important field of application has been the production of *ultrasonic waves*. Utilizing a small quartz membrane, the construction of the Nieı and other piezo indicators is described. Numerous applications are cited, such as indicator for injector efficiency in gas lines, vibration intensity, etc. C. G. F.

Primary electric battery. Erwin A. Schumacher and Geo. W. Heise (to National Carbon Co.). U. S. 2,180,839, Nov. 21. An anode of metal such as Zn which is sol. in alk. electrolyte is used with a carbon cathode capable of transferring O from the air to the cathodic polarizing region and with an alk. electrolyte such as NaOH soln. in admixt. with electrolyte-immobilizing material such as starch or cellulose pulp and dispersed solid electrolyte-regenerating material such as $Ca(OH)_2$ or bentonite. *Cf. *C. A.* **33**, 3704[1,2].

Primary electric battery. Geo. W. Heise and Erwin A. Schumacher (to Union Carbide and Carbon Corp.). U. S. 2,180,955, Nov. 21. A liquid electrolyte such as a caustic alkali soln., which tends to become exhausted by substances formed in it during the action of the battery, is used with an electrolyte-forming solid material within the battery, and a mass of material within the battery for removing such substances from soln. comprising a mixt. of a reactant such as lime, an "extender" such as cellulose fluff and a binder of the electrolyte-forming material.

Dry cells. Price Drummond (to Union Carbide and Carbon Corp.). U. S. 2,179,816, Nov. 14. Various structural details.

Storage battery. Carl J. Dunzweiler (to Willard Storage Battery Co.). U. S. 2,180,463, Nov. 21. Structural details.

Storage battery. Mark A. Hopkins (to Prest-O-Lite Storage Battery Corp.). U. S. 2,180,959, Nov. 21. Structural details.

Storage-battery cover. Edward W. Smith (to Electric Storage Battery Co.). Can. 386,478, Jan. 23, 1940. Structural details.

Electrolytic condensers. Joseph L. Collins (to Sprague Specialties Co.). U. S. 2,180,798, Nov. 21. Filming electrodes such as those of Al are subjected to chem. etching in an etching soln. such as a 5–20% HCl soln. and the temp. rise caused by the exothermic reaction is measured and utilized as an indicator of the degree of etching.

Electrolytic production of chlorates from chlorides. Lucien Delavenna and Jean Maillard. U. S. 2,180,668, Nov. 21. App. is described, and a method of producing chlorates of alkali and alk. earth metals and H by electrolysis from the corresponding chlorides in aq. soln. comprising circulating the electrolyte along a single path, under the action of the H developed by the electrolysis, between a closed and diaphragmless electrolytic cell and a vessel positioned at a level above the cell sufficient to produce a pressure in the cell of about 400 g. per sq. cm., maintaining the electrolyte satd. by const. addn. thereto, in the vessel, of the chloride in cryst. form, collecting the chlorate in the vessel, and permitting the escape of the H at the upper part of the vessel.

Electrostatic separation of particles of zircon and rutile from each other. Frank A. Fahrenwald, Norman F. Parkinson and Geo. H. Barnes (to International Titanium Ltd.). U. S. 2,180,804, Nov. 21. See Brit. 498,246 (*C. A.* **33**, 4140[4]).

Recovering dissolved material from sea water. Arthur E. Zoppa. U. S. 2,179,537, Nov. 14. App. is described, and a method utilizing the energy of sea waves to deliver sea water at a higher level, utilizing the head of water thus delivered to generate elec. energy, and employing such elec. energy for water treatment.

Protective systems for electric induction furnace installations. Philip G. H. Burbridge, Geo. F. Travis, Richard H. Black, Metropolitan-Vickers Electrical Co. Ltd. and Electric Furnace Co. Ltd. Brit. 506,665, June 1, 1939. Relay arrangements are provided whereby the furnace with its assocd. app. will be cut off automatically from the source of furnace supply and (or) other changes of operating conditions effected in the event of failure, for instance, of the furnace lining that permits interconnection of the furnace charge with the induction coil, or in event of an earth fault developing in any part of the furnace circuit.

Electric boiler for heating or evaporating materials such as biphenyl. Edward M. Frankel and Arthur Pollak (to West Virginia Pulp & Paper Co.). U. S. 2,179,781–2, Nov. 14. Various details of structure and operation, including thermostatic control.

Temperature control device for electric heaters. Lloyd L. Young (to Radio Corp. of America). U. S. 2,179,838, Nov. 14. Various structural, elec. and operative details.

Carbon electrodes. Béla Markó. Hung. 122,731, Jan. 2, 1940. Ten to 20 kg. pitch, asphalt, paraffin or dextrin is heated, mixed with 100 kg. powd. coal, graphite, metals or other elec. conductor, pressed to form and ignited in chamotte containers.

Electrodes for electric discharge devices. Eugene Lemmers and Geo. M. Carpenter (to General Elec. Co.). U. S. 2,180,988, Nov. 21. A highly porous body is formed by compressing coarse refractory metal particles such as those of W and momentarily passing a heavy elec. current through the particles to weld them together only at their contacting edges, and the porous body is impregnated with an electron-emissive material.

Electric contacts. Franz R. Hensel and Earl F. Swazy (to P. R. Mallory & Co.). U. S. 2,180,826, Nov. 21. Contacts such as those for use with heavy currents are formed of a compn. comprising Si 0.05–5.0%, refractory material selected from W, Mo or their carbides 10–75%, and a balance substantially all Ag, the refractory material mentioned being in a finely divided state intermixed and bonded by an alloy contg. Ag and Si (the compn. being substantially free from Cu). U. S. 2,180,827 (Franz R. Hensel and Kenneth L. Emmert, joint inventors; to same assignee) relates to contacts formed of Ag together with Mg 0.05–15 and Zn 0.5–25%, etc.

Laminated electric contacts. Joseph A. Payette (to Metals & Controls Corp.). U. S. 2,181,083, Nov. 21. An elec. contact button is provided with a disk having a Ag facing and a high elec. resistance ferrous metal backing (structural details being described).

Electrical make and break contacts. Franz R. Hensel and Kenneth L. Emmert (to P. R. Mallory & Co.). U. S. 2,180,845, Nov. 21. Contacts are formed of an alloy contg. Ag together with Tl 0.05–15%.

Metal-nitride compositions suitable for electrical contacts. Franz R. Hensel (to P. R. Mallory & Co.). U. S. 2,180,984, Nov. 21. One or more of the nitrides of Ti, Zr, Hf, V, Cb and Ta 25–75% is used together with about 50% or less of W or Mo or their refractory carbides, the balance of the compn. being Au, Ag or Cu.

Electrical resistor. Erwin R. Stoekle (to Globe-Union Inc.). U. S. 2,179,566, Nov. 14. A resistor which may be bent to fit a curved housing comprises a thin strip of metal such as Al or Cu provided with a flexible Japan coating and with a resistance coating such as a carbonaceous material of graduated specific resistance along its length on one side, so that heat transfer by the metals trip serves to increase the elec. load-carrying capacity of the resistor.

Mercury-arc rectifier. Clarence W. Hansell (to Radio Corp. of America). U. S. 2,179,929, Nov. 14. Structural details.

Alternating-current rectifiers of the copper oxide type. Albert L. Williams, Leslie E. Thompson and Roger H. Cubitt (to Union Switch & Signal Co.). U. S. 2,180,026, Nov. 14. A process for the manuf. of a. c. rectifiers of the Cu oxide type in which the exposure of the rectifier blanks to the contaminating action of the oxidizing atmosphere during the period when the temp. of the blanks is low is arranged to be reduced or prevented by coating the blanks prior to heating them in the oxidizing atm., with a layer of black material such as C, graphite or cupric oxide for the purpose of increasing the rate at which heat is absorbed by the blanks until the blanks reach the final oxidizing temp.

Dry-plate rectifier. Emil Rupp and Adalbert Sperling (to Canadian General Electric Co., Ltd.). Can. 386,395, Jan. 16, 1940. The rectifier comprises a W element having a Ni support, and a layer of WO_2 on the W element in contact with a metal layer of the group Pb, Zn, Bi and Ag supported on a layer sheet of other metal.

Photoelectric cell. Clarence W. Hewlett (to Canadian General Electric Co., Ltd.). Can. 386,396, Jan. 16, 1940. A light-sensitive device is prepd. by evapg. and condensing Se on a plate of base metal, heating above the m. p. of Se to melt the evapd. layer, cooling, heating to convert the Se into a metallic light-sensitive form, sputtering a film of Cd on the Se surface, sputtering a film of Pt on the Cd surface, and cooling the Pt film with an insulating protection layer at the places where elec. contact with the film is made.

High-vacuum production in devices such as "radio tubes." John D. McQuade (to Kemet Laboratories Co.). U. S. 2,180,714, Nov. 21. A wire of high elec. resistance with a coating of elec. insulation is used with a compd. getter wire having a core of an alk. earth metal and a shell of Ni or Fe or a Ni or Fe alloy and with a metal envelope which substantially encloses the getter wire and holds it in firm contact with the insulated resistance wire. Cf. *C. A.* **33**, 1556[4].

Incandescent filament and lamp. Gjon Mili (to Westinghouse Elec. & Mfg. Co.). U. S. 2,180,538, Nov. 21. A lamp suitable for use in production of sound tracks on film has an incandescible W coil filament slightly bent into an arc of less than 90° and having substantially straight end portions, supplemental coils formed of a metal, such

as Ni or a Ni-Fe alloy, of lower m. p. than W enclosing the end portions, and leading-in conductors, the coil- 1 covered end portions mentioned being welded to the leading-in conductors.

5—PHOTOGRAPHY

Recent developments in color photography. Gustav Grote. *Phot. Korr.* **74**, 17–22(1938); **75**, 103–7(1939); 2 cf. *C. A.* **31**, 2947⁵.—A review of recent patents in the following branches of color photography: screen processes; taking and projection; subtractive processes.
M. W. Seymour

Absolute color reproduction in photography with modern color films. Karl John. *Phot. Korr.* **75**, 113–19(1939).

Physics in color photography. David L. MacAdam. *J. Applied Phys.* **11**, 46–55(1940).—Review. S. L. G. 3

Spectral distribution of sensitivity of photographic emulsions sensitized by cyanine dyes. G. Schwarz. *Science ind. phot.* **10**, 233–41(1939).—Data are given which establish the existence of 2 types of color sensitizing for the cyanines. For most carbocyanines, the principal max. of the "sensitization of the 1st type" occurs at a wave length about 25–50 mμ longer, and the max. of the "sensitization of the 2nd type" occurs about 70–115 mμ longer, than the max. of absorption of the alc. soln. of the 4 dye. The max. of the 2nd type is very sharp; in some cases, this 2nd type of sensitization does not occur. One type of sensitization can be favored over the other by the choice of emulsions, and the production of the 2nd type can sometimes be encouraged by heating the sensitized emulsions. S. agrees in essentials with the conclusions of Leermakers, Carroll and Staud (*C. A.* **32**, 65¹), that the 2 types of sensitization correspond to 2 states of aggregation of the adsorbed dye mols. J. A. Leermakers 5

Use of spirals in emulsion coating and drying. Willy Nauck. *Phot. Ind.* **37**, 966–68(1939).—N. describes and discusses a method of handling film and paper in the drying operation which is stated to give several advantages over the current festoon method of drying. H. C. Carlton

The response of photographic materials to atomic particles. T. R. Wilkins. *J. Applied Phys.* **11**, 35–45 (1940).—Emulsions can be made in which no tracks are 6 produced even for α-rays and others in which α-ray but no proton tracks are discernible. Methods are described and useful equations and curves given for photographic counting of α-rays. Photographic emulsions can also be used for recording and identifying the tracks of individual particles. Descriptions are given of applications to the study of radioactive aggregates, counting of α-rays and protons, detn. of half-lives of radioactive elements, nuclear reactions in impregnated plates, detection of fission, cosmic rays, nuclear scattering and identification of radioactive isotopes. S. L. Gerhard

RCA aluminate developers. J. R. Alburger. *J. Soc. Motion Picture Engrs.* **33**, 296–314(1939).—The principle of operation and characteristics of a new developer described as a "peptized sol" buffer developer are given. The developer is characterized by the addn. of $KAl(SO_4)_2$ which reacts with the alkali (NaOH) to form an equil. soln. As the alkali is used up in the development reaction, the equil. is disturbed and the Al is pptd. as Al_2O_3. The function of the balanced soln. is to act as a buffer to hold the alky. of the soln. relatively low, while at the same time the ionization balance of the org. reducing agent is shifted so as to produce increased energy of the developer. Advantages of this developer are: long useful life with little replenishment, higher contrast and improved resolution for variable-area recordings and release prints, effective emulsion speed, γ and d. reasonably const. throughout the life of the developer, temp. effect greatly reduced, d. tolerances for variable-area recording increased approx. 100%, and the developed image hardened in the developer owing to the $Al(OH)_3$ present. J. G. S.

Chemical analysis of hydroquinone, metol and bromide in a photographic developer. H. L. Baumbach. *J. Soc. Motion Picture Engrs.* **33**, 517–24(1939).—The usefulness of chem. analysis as a supplement to sensitometric data is emphasized. Distribution ratios for hydroquinone and metol between H_2O and ether are given as functions of Na_2SO_3 concn. and pH. A new analytical method is presented for the detn. of metol and hydroquinone in a photographic soln. where the developing agents are salted out of the soln. at the proper pH by means of Na_2SO_3 and detd. volumetrically by titration with I_2. A modified Volhard method is presented for the detn. of sol. bromide where the interfering substances are removed by treatment with H_2O_2. Author

Photographic desensitizers. A. V. Belosvetov and V. A. Izmailovskiĭ. *Uspekhi Khim.* **8**, 546–60(1939).—Remarks on the paper by Seyewetz (cf. *C. A.* **32**, 66¹).
F. H. Rathmann

Theory of the photographic latent-image formation. J. H. Webb. *J. Applied Phys.* **11**, 18–34(1940).—The Gurney-Mott theory (*C. A.* **32**, 4449⁹) assumes, in agreement with earlier theories, that the latent image itself is a submicroscopic speck of Ag, but goes further by explaining its formation in terms of modern physics. The photocond. of AgBr allows the migration of electrons, which are trapped by colloidal Ag or Ag_2S particles. The ionic cond. of AgBr, ascribed to the thermal movement of interstitial Ag ions, allows the latter to be attracted to the specks negatively charged by trapped electrons, thereby forming Ag atoms, 1 for each light quantum absorbed by the crystal. Temp. effects, reciprocity-law failure, intermittency effect and Herschel effect are explained in terms of the theory. Bibliography. S. L. Gerhard

Tone separation. Helmer Bäckström. *Nord. Tids. Fot.* **23**, 196–98, 212–15(1939).—In a method for printing from a negative of excessive d. range, the bromide paper is soaked in the developer for about 4 min., given a partial exposure, allowed to remain on the enlarging board 6 about 2 min., then given the remainder of the exposure and finally developed. O. Sandvik

Three-color prints by chemical toning. Aloysius Sullivan. *Photo Art Monthly* **7**, 483–7(1939).—Bromide prints are protected locally by a soln. of wax in gasoline and then toned with a bath to convert the remaining area of the print to a $PbCrO_4$ (yellow) image. The wax is removed and the procedure repeated with the wax for 2 7 other tones, i. e., Ni dimethylglyoxime (magenta), and ferric ferrocyanide (blue). G. E. Matthews

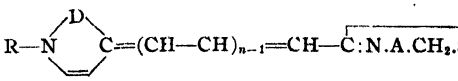
Multicolor photography. Gustav Wilmanns, Wilhelm Schneider and Gerhard von Kujawa (to Agfa Ansco Corp.) Can. 386,563, Jan. 30, 1940. A colored negative is produced on a multilayer material having each layer differently light-sensitized and contg. a color former fast to diffusion selected so that the colors of the neg. are about the same as those of the photographed object. A multicolor print is printed directly onto a photographic multilayer material contg. color formers fast to diffusion selected so that the pos. colors in the material correspond exactly to those of the object to be reproduced.

Photographic developer. Louis C. Jones, Robert B. Barnes and Garnet P. Ham (to American Cyanamid Co.). U. S. 2,179,790, Nov. 14. In a developer for Ag halides, a quaternary ammonium hydroxide such as trimethylbenzylammonium hydroxide is used as an alky.-producing agent.

Sensitizing photographic emulsions. Kodak-Pathé. Fr. 840,957, May 8, 1939. The sensitizing action of certain compds. is increased by the presence of "supersensitizers." Thus the sensitization of a silver halide gelatin emulsion by compds. of the type of pinacyanol is increased by the presence of styryl compds. comprising a heterocyclic ring contg. nitrogen. The same supersensitizers increase the effect of pseudocyanines that have one heterocyclic ring contg. N and another ring contg. N, and which may contain S or Se, such as the thiapseudocyanines or the selenapseudocyanines. The effect of thiacarbocyanines or selenacarbocyanines is increased by dibenzothiacarbocyanines; that of 8-alkylcarbocyanines contg. S or Se is increased by a pseudocyanine compd.; that of oxaselenazolocarbocyanines or oxathiazolocarbocyanines which may contain in position 4' an alkyl or an aryl group, by a pseudocyanine compd. Usually 1 part of supersensitizer for 10 parts sensitizer is sufficient. Both supersensitizer and sensitizer, in the desired proportions, are dissolved in an org. solvent, preferably MeOH, and this soln. is added to the silver halide emulsion.

Photographic material. Walter Frankenburger and Hermann Schulz (to Agfa Ansco Corp.). U. S. 2,180,409, Nov. 21. A material suitable for use in color photography comprises a Ag halide emulsion layer contg. a phthalocyanine, sulfonated phthalocyanine or metal phthalocyanine dye.

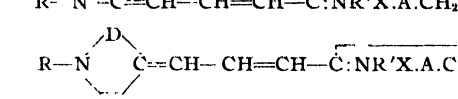
Hardening photographic gelatin layers, etc. Johannes Brunken (to Agfa Ansco Corp.). U. S. 2,180,335, Nov. 21. See Can. 383,373 (*C. A.* **33**, 8334[9]).



Photographic backing paper. Ernest L. Baxter (to Eastman Kodak Co.). U. S. reissue 21,268, Nov. 21. A reissue of original patent No. 2,153,130 (*C. A.* **33**, 4896[1]).

Photographic corrected color-separation images. Arthur C. Hardy (to Interchemical Corp.). U. S. 2,179,786, Nov. 14. A method of producing a corrected color component image of a colored object by use of a photographic element having 2 sensitive layers permanently attached to a support involves forming a negative image of one of the primary color components of the colored object in one of the sensitive layers, forming a positive image of another of the primary color components of the colored object in the other sensitive layer, the positive image being superposed and in register with the negative image, and printing both images simultaneously to form a corrected color component record of the colored object. A relatively fast back layer of negative emulsion is used with a relatively slow front layer of positive photographic emulsion, both being sensitized with suitable dyes.

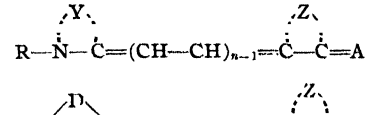
Dyes and dye bases. Bernard Beilenson (to Eastman Kodak Co.). U. S. 2,179,990, Nov. 14. Dye bases of the general formulas



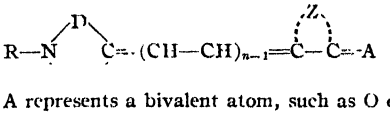
or

where A and D represent phenylene groups, *n* represents a positive integer not greater than two, R represents an alkyl group and Z represents the nonmetallic atoms necessary to complete a five-membered or six-membered heterocyclic nucleus, e. g., R can represent an alkyl group, such as Me, Et, Bu, allyl, β-ethoxyethyl or benzyl and Z can represent the nonmetallic atoms necessary to complete a five-membered heterocyclic nucleus, such as a thiazole, a 4-methylthiazole, a 4-phenylthiazole, a benzothiazole, a 4-chlorobenzothiazole, an α-naphthothiazole, and β-naphthothiazole, a thiazoline, a benzoxazole, an α-naphthoxazole, a β-naphthoxazole or a benzoselenazole or Z can represent the nonmetallic atom or atoms necessary to complete a six-membered heterocyclic nucleus, such as a quinoline nucleus, are prepd. by condensing a 3-methyl-2,4-benzothiazine with a cyclammonium quaternary salt contg. a reactive group, such as an iodine atom, an alkylthiol, an arylthiol group or a β-arylaminovinyl group for example, in the α- or γ-position. Heat and use of a basic condensing agent facilitate the formation of the dye bases, and these bases can be converted into cyanine dyes by heating the bases with alkyl *p*-toluenesulfonates or alkyl sulfates for several hrs. at about 150°. The resulting cyanine toluenesulfonates or alkyl sulfates can then be converted into the corresponding cyanine iodides or perchlorates for example by treatment with soluble iodides or perchlorates. The new carbocyanine dyes obtainable can be represented by the general formulas:

or



where A and D represent phenylene groups, R and R' represent alkyl groups, X represents an acid radical and Z represents the nonmetallic atoms necessary to complete a five-membered or six-membered heterocyclic nucleus. These dyes are useful for spectrally sensitizing photographic Ag halide emulsions. Numerous examples with details are given.



Dyes from imidazolones. Leslie G. S. Brooker (to Eastman Kodak Co.). U. S. 2,177,403, Oct. 24. Numerous examples are given of the production of *photographic sensitizing dyes* such as 3-ethyl-5-(3-methyl-2-thiazolinylideneethylidene) - 1 - phenyl - 2 - thio - 2,4(3,5)-imidazoledione, 3 - ethyl - 5 -(2 - ethyl - 1 - benzoxazolylidenecthylidene) - 1 - phenyl - 2 - thio - 2,4(3,5) - imidazoledione, 5 - (2 - ethyl - 1 - benzothiazolylideneethylidenc)-1,3 - diphenyl - 2 - thio - 2,4(3,5) - imidazoledione, and the like, which are obtained by condensing a cyclammonium quaternary salt, such as an oxazole, a thiazole, a thiazoline, a selenazoline, a selenazole, a pyridine or a quinoline quaternary salt, contg. a mercapto group in the α- or γ-positions, with an imidazolone contg. a nuclear reactive carbonyl or thiocarbonyl group, advantageously in the presence of a basic condensing agent.

Dyes from thiazolones. Leslie G. S. Brooker (to Eastman Kodak Co.). U. S. 2,177,402, Oct. 24. Numerous examples with details are given of the production of dyes suitable for use as special *sensitizers in photographic emulsions*, such as 2-diphenylamino-5-(2-ethyl-1-benzoxazolylideneethylidene) - 4(5) - thiazolone, or 2 - diphenylamino - 5 - (2 - ethyl - 1 - benzothiazolylideneethylidene) - 4(5) - thiazolone, which may be obtained, e. g., by condensing a cyclammonium quaternary salt, such as an oxazole, a thiazole, a thiazoline, a selenazole, a selenazoline, a pyridine or a quinoline quaternary salt, contg. a substituted mercapto group in the α- or γ-positions, with a thiazoline contg. a nuclear reactive methylene group, i. e., a nuclear methylene group adjacent to a nuclear carbonyl or thiocarbonyl group, advantageously in the presence of a basic condensing agent. 1

Dyes from thioöxazolediones. Leslie G. S. Brooker (to Eastman Kodak Co.). U. S. 2,177,401, Oct. 24. Dyes suitable for use as special *sensitizers with photographic gelatino-AgCl and -AgBr emulsions* and which have the general formulas 2

and

wherein A represents a bivalent atom, such as O or S, D represents a vinylene or phenylene group, *n* represents a positive integer not greater than three, R represents an alkyl group, Y represents the nonmetallic atoms necessary to complete a five-membered or six-membered heterocyclic nucleus, such as an oxazole nucleus (for example oxazole, benzoxazole or naphthoxazole), a thiazole nucleus (for example thiazole, benzothiazole or naphthothiazole), a selenazole nucleus (for example selenazole or benzoselenazole), a thiazoline nucleus, a selenazoline nucleus, a quinoline nucleus, a benzoquinoline nucleus or a pyridine nucleus and Z represents the nonmetallic atoms necessary to complete a thio-2,4(3,5)-oxazoledione nucleus, can, e. g., be prepd. by condensing a cyclammonium quaternary salt, such as an oxazole, a thiazole, a selenazole, a thiazoline, a selenazoline, a pyridine or a quinoline quaternary salt contg. a mercapto group in the α- or γ-position, i. e., one of the so-called reactive positions, with a thio-2,4(3,5)-oxazoledione, contg. a nuclear reactive methylene group, i. e., a nuclear methylene group adjacent to a nuclear carbonyl or thiocarbonyl group, advantageously in the presence of a basic condensing agent. The reaction, e. g., may involve the condensation of 1-phenylthiobenzothiazole ethiodide with 2-thio-2,4(3,5)-oxazoledione in the presence of Et_3N. Such a dye is called 5-(2-ethyl-1-benzothiazolylidene)-2-thio-2,4(3,5)-oxazoledione. In carrying out this type of condensation, it is advantageous to employ strong tert. org. bases as condensing agents, though inorg. condensing agents such as Na_2CO_3 or KOH can be used. Heating accelerates the reaction. Numerous examples with details of procedure are given. 3 4

Katsurai

Reaction between nitric acid and tin in presence of catalysts. II. G. S. Kasbekar and A. R. Normand. *Proc. Indian Acad. Sci.* **10A**, 37–40 (1939); cf. *C. A.* **31**, 7733¹.—Iodides of Na and K retard the reaction between HNO_3 and Sn. This retardation may be due to the specific action of the alkali ions. Molar solns. of NaI, KI and LiI inhibit the reaction for about 3 months and thereafter cause the formation of a thin layer of stannous iodide on the surface of the tin; this behavior is due to the formation of the oxidation products of HI in the reaction mixt. Helen S. Hopfield

The thermal and photochemical oxidation of the chlorinated silanes. H. J. Emeléus and A. J. E. Welch. *J. Chem. Soc.* **1939**, 1928–37.—The inflammability of the chlorinated silanes decreases with increasing chlorination. An investigation of the explosive limits for the thermal oxidation indicates a gradual transition from a degenerate chain reaction for $SiHCl_3$ to probably a branched chain reaction for SiH_3Cl. $Si(OH)Cl_3$ was isolated in the photo-oxidation of $SiHCl_3$ and the oxidation of the other chlorinated silanes is believed to take place through a similar primary hydroxylation process. $Si(OH)Cl_3$ decomposes slowly at room temp. to HCl and $SiOCl_2$. W. B. K.

Decomposition of mercuric ferrocyanide. Angel A. Bombelli. *Anales asoc. quím. argentina* **27**, 172–7 (1939).—$Hg_2Fe(CN)_6$ is a compd. of little stability and very sensitive to heat. In the presence of H_2O it breaks down to $2Hg(CN)_2 + Fe(CN)_2$. Its blue color is due to formation of ferric ferrocyanides by hydrolysis, oxidation and polymerization of $Fe(CN)_2$. E. M. Symmes

Constitution of cyano derivatives of gold. Charles S. Gibson. *Proc. Roy. Soc.* (London) **A173**, 160–1 (1939).—A zig-zag chain of alternate auric Au atoms (each linked to 2 Pr groups) and aurous Au atoms sepd. from each other by CN groups is proposed as the structure of dipropyldicyanodigold (I), $Pr_2Au_2(CN)_2$, which is obtained from Pr_2AuCN (II) by loss of half of the Pr radicals. I is insol. in H_2O and all org. solvents. Further loss of Pr radicals may be expected to produce aurous cyanide, a straight-chain structure. R. F. D. 6

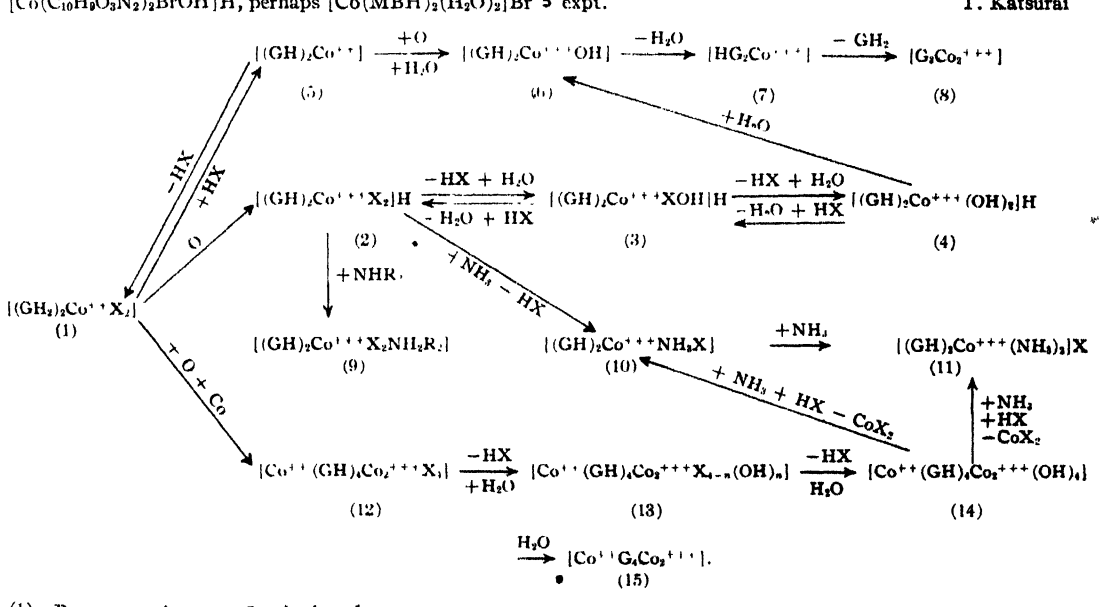
The structure of copper salts of some complex cyanic compounds. I. The structure of copper salts of hexacyanides of cobalt and chromium. Mario A. Rollier and Enrico Arreghini. *Gazz. chim. ital.* **69**, 499–508 (1939).—When an excess of $CuSO_4$ was added to aq. $K_4Co(CN)_6$ (cf. Szegö and Ostinelli, *C. A.* **25**, 2917) at −13° with exclusion of air, a slightly exothermic reaction took place and a green ppt. was formed, which, dried *in vacuo*, yielded a stable, pale-green *substance* (I) contg. 41.75% Cu, 9.46% Co and 37% CN. It was not, therefore, a hexacyanide. That its magnetic moment was very low, indicated that a considerable proportion of the Cu was in the cuprous form. Perhaps CuCN was formed during the pptn. of $Cu_2Co(CN)_6$ at the expense of the conversion of Co from the cobaltous to the cobaltic form. I, washed with hot HCl (1:1), left 56.8% of the original wt. of a more intense green, stable *compd.* (II) contg. Cu 23.18, Co. 14.41, CN 38.0%. The green HCl ext. contained Cu but no Co. On the anhyd. basis, the compn. of II corresponded to $Cu_3[Co(CN)_6]_2$, in which all Cu is cupric and all Co is cobaltic. The absence of cobaltous Co was confirmed by soln. in 20% aq. KOH, and addn. of Seignette salt. No H was evolved nor was Cu_2O pptd., both of which reactions would have happened if bivalent Co had been present. The results indicate that II is *cupric cobalticyanide*, $Cu_3[Co(CN)_6]_2$ contg. 24.4% H_2O. The magnetic properties of II were detd., to confirm the absence of univalent Cu in II, and of $Cu_2Fe(CN)_6$ (III) and $CuK_2Fe(CN)_6$ (IV) to be 7 8 9

certain that Cu does not show any anomalous behavior in II. In prepg. III and IV by the method of Rigamonti (*C. A.* **31**, 6574[6]), it was found easier to prep. pure IV by using a large excess of $K_4Fe(CN)_6$ and a soln. contg. K_2SO_4 and $CuSO_4$ in a 4:1 ratio. After drying over P_2O_5 *in vacuo* (20 mm.) at room temp., III contained 30.8%, II 24.4% and IV 1.5% of H_2O. The following data give the temp., magnetic susceptibility (per g. χ. 10^6) and magnetic moment (in magnetons), of II, III and IV, resp.: 19° 5.60, 1.91; 19°, 5.99, 1.86; 17°, 3.80, 1.81. The magnetic moments are close to the 1.73 value which corresponds to 1 spinning electron, and it is in accord with the presence of only bivalent Cu in each compd. and with the absence of paramagnetism. Prepd. in the same way as II, *cupric chromohexacyanide*, $Cu_2Cr(CN)_6$ (V) is green and unstable (decompn. probably to $Cu(CN)_2$ and $Cr(CN)_2$). The unit cell of II contains 2 mols. and has a base dimension of 9.91 ± 0.05 A. The cell of V contains 4 mols., with a base dimension of 10.22 ± 0.05. The essential identity of structure of II, V, ferricyanides, ferrocyanides, cobalticyanides, chromocyanides and manganocyanides (to be described later) depends on the fact that the fundamental cryst. structure or skeleton is not the $M(CN)_6$ complex but a $[M^{+++}(CN)_6M^{++}]^{-}$, $[M^{++}(CN)_6M^{+++}]^{-}$ or $[M^{+++}(CN)_6M^{+++}]$ group, common to all. In each case, 4 such groups constitute the skeleton of the elementary cell. The structure is shown schematically by a detailed 3-dimensional diagram, and is thus correlated with data of other investigators on the same type of compds. Although derived in a different way, the structure assigned to these compds. as a result of the present work is essentially the same polynuclear complex type assigned by Cambi and Clerici for ferrous chromicyanides, manganicyanides and ferricyanides (cf. *C. A.* **22**, 2523). The results suggest that the structure of Prussian blue may be $[Fe^{++}(CN)_6Fe^{+++}]K.2H_2O$, i. e., the $4[Fe^{++}(CN)_6Fe^{+++}]$ groups constitute the skeleton of the elementary cell, within which are K atoms and at least 4 of the 8 H_2O mols. C. C. Davis

The theory of complex compounds. Anna D. Hel'man. *Compt. rend. acad. sci. U. R. S. S.* **24**, 549–52(1939)(in English).—The behavior of C_2H_4, CO and NO in Pt coordination compds. is readily explained by the assumption of high trans influence (Chernyaev, *C. A.* **23**, 2616), whereby the Pt acts first as an electron donor to the activated C_2H_4, CO or NO and then becomes an acceptor; this results in the formation of a 4-electron covalent bond and high activity of the inner sphere. Complex compds. with unsatd. mols. are formed only by bivalent Pt, and generally by metals in the lowest stage of oxidation. Only one unsatd. mol. of high trans influence can become a part of the complex and it is easily displaced by an excess of NH_3 or pyridine. Two or three mols. of thiourea can enter the complex since it is an electron donor only and can give four electrons for common use.

George Ayers

Cobalt salts of glyoximes. V. Livio Cambi and Lamberto Malatesta. *Gazz. chim. ital.* **69**, 547–61(1939); cf. *C. A.* **30**, 8160[1]; *Rend. ist. lombardo sci.* **71**, 327(1938).—Various complex cobaltous and cobaltic derivs. of α-glyoximes and their hydrolytic products are described. In this work, RC(.NOH)C(:NOH)R is abbreviated to GH_2, the RC(:NO—)C(:NOH)R radical to GH, the RC(:NO—)C(:NO—)R radical to G; α-monophenylglyoxime (I) and its radicals to MPIIf, MPH and MP, resp.; α-methylbenzoylglyoxime (II) and its radicals to MBH_2, MBH and MB, resp., and α-diphenylglyoxime (III) and its radicals to DPH_2, DPH and DP, resp. *Derivs. of* III.—$CoBr_2$ (22 g.) in abs. EtOH and 48 g. III, allowed to stand at 60° until crystn. is complete, 50 cc. fuming HBr added, refluxed for 1 hr., allowed to crystallize and fractionally crystd. from $CHCl_3$, yield the complex *bromide*, $[Co(C_{14}H_{11}O_2N_2)_2Br_2]H$ (IV), black en masse, green when pulverized; magnetic susceptibility (hereafter designated χ_M and χ_A) -320×10^{-6}, 26×10^{-6}. The mother liquor yields less-brominated compds. with ill-defined Co:glyoxime ratios (less than 1:2). IV (10 g.), 100 cc. abs. EtOH and 20 g. KOAc, refluxed for 15 min., yield the *hydrate*, $[Co(C_{14}H_{11}O_2N_2)_2(OH)_2]H.H_2O$, maroon-red, χ_M and χ_A at 18°, 208×10^{-6} and 104×10^{-6}, resp., loses 1 H_2O mol. at 120° *in vacuo* over P_2O_5. Above 120° it decomp. more profoundly. Direct pptn. of the anhyd. cobaltous salt is impossible because of the insoly. of III in all solvents. However, by refluxing a mixt. of III and $Co(OAc)_2$ in anhyd. Me_2CO, there is pptd. the *anhyd. cobaltous salt*, $[Co(C_{14}H_{11}O_2N_2)_2]$, black; χ_M and χ_A at 18°, 1512×10^{-6} and 1740×10^{-6}, resp., while the *cobaltic salt*, $[Co(C_{14}H_{11}O_2N_2)_2OH]$, remains in soln. and can be pptd. by water. *In vacuo* over P_2O_5 at 120°, it is dehydrated to the *cobaltic salt*, $[Co(C_{14}H_{10}O_2N_2)H]$, χ_M and χ_A -251×10^{-6} and 30×10^{-6}, resp. Attempts to prep. NH_4 salts of the $[Co(GH)_2Br_2]-NH_2R_2$ type by the use of Bu_2NH gave only indefinite products, but with Bz_2NH salification of the acid and simultaneous substitution of Br by OH take place. The product has the compn. $[Co(DPH)_2Br_{1.36}(OH)_{0.64}]-Bu_2NH_2$ and is probably a mixt. of 68% of the *cobaltic compd.*, $[Co(DPH)_2]Bu_2NH_2$, and the *cobaltic compd.*, $[Co(DPH)_2(OH)_2]Bu_2NH_2$. The mixt. showed χ_M and χ_A values at 18° of 455×10^{-6} and 16×10^{-6}, resp. *Derivs. of* I.—I (32 g.) in abs. EtOH and fuming HBr (several cc.), heated at 60–70°, 18 g. $CoBr_2$ added during 2 hrs. with continuous passage of dry air, kept hot for 2 more hrs. in dry air, boiled, filtered and allowed to stand, ppts. the *bromide*, $[Co(C_8H_7O_2N_2)_2Br_2]H$ (V), dark green; χ_M and χ_A at 18°, -209×10^{-6} and 48×10^{-6}, resp. It is also formed by treating the product of Na cobaltinitrite and I (2 parts) with fuming HBr and purifying by EtOH. With excess Bu_2NH in EtOH, an NH_4 salt is not obtained, and the alky. of the medium leads to partial hydrolysis of the Br of the pseudo acid: the product is the *compd.* $[Co(C_8H_7O_2N_2)_2Br(C_4H_{11}N)]$. V (10 g.) and KOAc in abs. EtOH, heated for 4 min. on a steam bath, yield, after drying over P_2O_5 (tendency toward a partial loss of I with probable formation of the sesqui salt, $Co_2(MP)_3$), the *cobaltic compd.*, $[Co(C_8H_7O_2N_2)_2(OH)_2]H$. It is difficult to obtain reasonably pure, e. g., in 2 of several prepns., χ_M at 18° was -192×10^{-6} and -202×10^{-6}, χ_A was 34×10^{-6} and 14×10^{-6}. I and $CoBr_2$ in abs. EtOH, maintained for several hrs. at 50–60°, ppt. the *cobaltous-cobaltic bromide*, $[Co(C_8H_7O_2N_2)_4Br_{3.8}-(OH)_{0.2}].6EtOH$, maroon-yellow, χ_M and χ_A 8944×10^{-6} and 9475×10^{-6}, resp. It loses its 6 EtOH mols. at 80–100°. Its constitution is probably $[Br_2Co^{+++}(MPH)_2]-Co^{++}[(MPH)_2Co^{+++}BrOH]$ (VI). VI and satd. alc. NH_3 heated on a steam bath ppt. the yellow *ammoniate*, $[Co_3(C_8H_6O_2N_2)_4(NH_3)_4(HBr)_2]4H_2O$ (VII), which, *in vacuo* at 120°, gives the *anhyd. compd.*, to which is attributed the constitution $Br[(NH_3)_2Co^{+++}(MPH)MP]-Co^{++}[MP(MPH)Co^{+++}(NH_3)_2]Br$ (VIII). At 18° χ_M is 8980×10^{-6}, χ_A 9487×10^{-6}. Cobaltous Co is proved by these values and by its decompn. to cobaltous compds., which also show that the NH_3 is united directly to cobaltic Co. Thus, mineral acids yield $[Co^{+++}(NH_3)_2(MPH)_2]X$ salts, *e. g.*, VIII in dil. AcOH and concd. HBr ppt. the dark yellow *cobaltic bromide*, $[Co(C_8H_7O_2N_2)_2(NH_3)_2]Br$, χ_M and χ_A at 18° -263×10^{-6} and 10×10^{-6}, resp. VIII in dil. EtOH and dil. HNO_3 ppt. the yellow *cobaltic nitrate*, $[Co(C_8H_7O_2N_2)_2(NH_3)_2]NO_3$, χ_M at 18°, -271×10^{-6}. VIII and $HClO_4$ yield the *cobaltic perchlorate*, $[Co(C_8H_7O_2N_2)_2(NH_3)_2]ClO_4$, χ_M at 18°, -274×10^{-6}. VIII in dil. AcOH and $K_2S_2O_8$ yield the *cobaltic persulfate*, $[Co(C_8H_7O_2N_2)(NH_3)_2]_2S_2O_8$, χ_M at 18°, -515×10^{-6}. VIII and H_3PO_4 yield the *cobaltic acid phosphate*, $[Co(C_8H_7O_2N_2)_2(NH_3)_2]HPO_4$, χ_M at 18°, -503×10^{-6}. These reactions are double decompns. and show that, in AcOH, VIII decomps. thus: $VIII \xrightarrow{+AcOH} 2[Co^{+++}(MPH)_2(NH_3)_2]Br + Co(OAc)_2$. In boiling water for 10 min. (the soln. is maroon-red), VI ppts. the *cobaltic hydroxide*, $[Co(C_8H_7O_2N_2)_2Br(OH)]H$, χ_M and χ_A at 18°, -202×10^{-6} and 8×10^{-6}, resp. The mother liquor contains approx. 1/3 of the Co as cobaltous ions. VI in boiling C_5H_5N for several min. ppts. the yellow *cobaltic pyridine bromide*, $Co(C_8H_7O_2N_2)_2(C_5H_5N)Br$, χ_M and χ_A at 18°, -248×10^{-6} and 17×10^{-6}, resp. Chilling of



the mother liquor ppts. maroon *cobaltous-cobaltic pyridine bromide*, $[Co^{+++}(C_8H_7O_2N_2)_2(C_5H_5N)Br].CoBr_2$ (IX). It is stable only in the presence of C_5H_5N and on drying it becomes sky-blue, because of decompn. into the simpler *cobaltic pyridine bromide*, $[Co(MPH)_2(C_5H_5N)Br]$ (X) and $CoBr_2$. The blue mixt. showed χ_M and χ_A values at 18° of 9310 × 10^{-6} and 9625 × 10^{-6}, resp.; X, −250 × 10^{-6} and 15 × 10^{-6}, resp. In confirmation of these results, $CoBr_2$ and I in C_5H_5N in air formed X. On the other hand IX could not be prepd. by this method. VI and KOAc in abs. EtOH, heated for 20 min. on a steam bath, ppt. the complex *hydrated cobaltic hydroxide*, $[Co_3(C_8H_7O_2N_2)_4(OH)_4].4H_2O$. *In vacuo* at 100° it forms the *anhyd. hydroxide*, $Co_3(C_8H_7O_2N_2)_4(OH)_4$, the χ_M and χ_A values at 18° of which are 9110 × 10^{-6} and 9523 × 10^{-6}, resp. In an inert atm., alc. I and $Co(OAc)_2$ ppt. the violet-red *cobaltous salt*, $Co(C_8H_8O_2N_2)_2$, χ_M and χ_A 1525 × 10^{-6} and 1719 × 10^{-6}. It is difficult to filter and its aq. solns. tend to turn dark and decomp., so that it can be obtained pure only with great difficulty. The progressive decompn. was followed by analyses and magnetic measurements. All products analyzed to the point where the Co·N ratio was 1:2.98 were highly paramagnetic and therefore the product is not $[Co^{+++}(DP)(DPH)]$ or $[Co_2^{+++}(DP)_3]$, but is probably a cobaltous-cobaltic salt. *Derivs. of* II.—II (20 g.) and 15 g. $CoBr_2$ in abs. EtOH, exposed to air for 2 hrs., 66% aq. HBr (100 cc.) added dropwise (cooling), the ppt. dried *in vacuo* over KOH and purified by C_6H_6, yield the green *bromide*, $[Co(C_{10}H_2O_2N_2)_2Br_{1.5}(OH)_{1.5}]H$ (XI), χ_M and χ_A at 20°, −105 × 10^{-6} and 164 × 10^{-6}, resp. Its concd. alc. solns., dild. with cold water, ppt. a compd. $[Co(C_{10}H_9O_3N_2)_2Br_{1.5}(OH)_{1.5}]$ (XII), χ_M and χ_A at 20°, −105 × 10^{-6} and 164 × 10^{-6}, resp. Its concd. alc. solns., dild. with cold water, ppt. a *compd.* $[Co(C_{10}H_9O_3N_2)_2BrOH]H$, perhaps $[Co(MBH)_2(H_2O)_2]Br$ or a partial hydrolytic product $[Co(MBH)_2Br(OH)]H$. Its χ_M and χ_A values at 20° are −165 × 10^{-6} and 92 × 10^{-6}, resp. Aq. XII, boiled for 1 hr., ppts. a yellow *hydrated cobaltic compd.*, $Co_3(C_{10}H_9O_3N_2)_3.6H_2O$ (XIII). A similar compd. (XIV) is obtained by pptn. from a soln. of XII in dil. NaOH by dil. AcOH. Anhyd. compds. could not be prepd., since at 80° XIII and XIV decomp. XIII and XIV are diamagnetic. The general results of the previous expts. and those described in the present paper can be correlated best by reference to the accompanying schematic outline of the reactions and products.

C. C. Davis

Racemization of optically active coördination compounds. Application of the Arrhenius equation. E. Bushra and C. H. Johnson. *J. Chem. Soc.* 1939, 1937–45. —Optically active forms of $[Cr\ en\ (C_2O_4)_2]^-$ (I) were prepd. and the rates of racemization of I, $[Cr(C_2O_4)_3]^{---}$ (II), and $[Co(C_2O_4)_3]^{---}$ (III) were investigated at several temps. in water and in aq. Me_2CO. Inversion occurs through intramol. rearrangement of the coördinated radicals. In the aq. soln. at 18° the rate of inversion of II was nearly 20 times as fast as that of III, the values of E being 15.75 and 26.0 kg.-cal., resp., and of log PZ 8.05 and 14.5, resp. Univalent cations at high concns. accelerate the racemization of II and III, but not of I. Multivalent cations at low concns. accelerate the racemization of I and II, but not of III, and this effect is even more pronounced with respect to II in aq. Me_2CO. W. B. K.

Studies on the catalytic oxido-reduction of some metallic complex salts. XII. Catalytic oxidation of pyrogallol by the complex salts of platinum group. Syoitiro Kawakubo. *J. Chem. Soc. Japan* 60, 1031–6(1939); cf. Yamasaki, *C. A.* 30, 7019⁴.—Generally, the ammine complex salts of Pt, Pd, Rh and Ru have no catalytic action; some of them even show retarding action. The catalytic action of metallic complex salts depends on their constitution and on the nature of the central metal. **XIII. Reduction of quinone by hydrogen in the presence of [Pd en]Cl₂.** Yuzi Sibata and Eizi Matumoto. *Ibid.* 1173–6.—$[Pd\ en]Cl_2$ accelerates the catalytic reduction of quinone. If the absorbed quantity of H is expressed by C, and time by t, $K = C/\sqrt{t}$ gives a const. value for each expt.

A new class of ammines of the thiostannate complexes. G. Spacu and A. Pop. *Bull. sect. sci. acad. roumaine* 21, 52–61 (1938–39).—See *C. A.* 33, 7689⁶. J. E. D.

A new class of complex ammines belonging to the group of iron and cobalt dinitrosothiosulfates. G. Spacu and C. Gh. Macafovici. *Bull. sect. sci. acad. roumaine* 20, No. 6, 1–11(1938).—See *C. A.* 33, 7690¹. J. E. D.

Studies of ionization in nonaqueous solvents. II.

The formation of certain ammines. Wm. L. German and R. A. Jamsett. *J. Chem. Soc.* **1939**, 1337–41; cf. *C. A.* **32**, 8294[9].—The reactions between salts and NH_3 in solns. in MeOH and in EtOH resemble those between solid salts and gaseous NH_3 rather than those that occur in aq. salt solns. with ammonium hydroxide. The compn. of the compds. formed was obtained by cond. titrations in the nonaq. solvents. The following compds. were found in MeOH: $Ag(NH_3)_2NO_3$, $Cu(NH_3)_2Cl_2$, $HgCl_2.2NH_3$, $CoCl_2.2NH_3$, $Cd(NH_3)I_2$, $CaCl_2.2NH_3$, and $Ni(NH_3)_2Cl_2$. The following compds. were found in EtOH: $Ag(NH_3)_2NO_3$, $Cu(NH_3)_2Cl_2$, $HgCl_2.1.5NH_3$, $CoCl_2.2NH_3$, $Cd(NH_3)_2I_2$, $CaCl_2.2NH_3$ and $Ni(NH_3)Cl_2$. 1

Kenneth H. Slagle

A study of complex compounds of platinum and complex amines. A. M. Rubinshtein. *Compt. rend. acad. sci. U. R. S. S.* **24**, 559–61(1939)(in English); cf. *C. A.* **33**, 6744[4].—K_2PtCl_4 and 5-iodo-2-aminopyridine (= iampy) in alc. slowly deposit a green ppt. of $PtCl_2.2iampy$, which when dissolved in C_5H_5N (= py) and heated 30–60 min. on the water bath gives a yellow ppt. of $PtCl_2.2py$. The latter compd., when heated on the water bath with thiourea (= th), and the resulting material acidified with HCl, gave 2th.2py. $PtCl_2$, which according to Kurnakov's rules, indicates that $2py.PtCl_2$ and $PtCl_2.2iampy$ have trans configurations. $PtCl_2.2C_5N_2H_6$, produced from α-aminopyridine and K_2PtCl_4, when treated with C_5H_5N, gives $(C_5N_2H_6)_2.2py.PtCl_2$ (I); this agrees with Jörgensen's rule. I and K_2PtCl_4 give grayish pink $[(C_5N_2H_6)_2py_2Pt].PtCl_4$. When Cl_2 is passed through a soln. of I, insol. red $[(C_5N_2H_4Cl_2)_2.2py.Cl_2Pt].Cl_2$ is formed. The elec. cond. of solns. of I indicates a tetrammine structure. I after prolonged heating with concd. HCl gives yellow $C_5N_2H_6.py.Cl_2Pt$. Thus, in $PtCl_2.2iampy$ the 5-iodo-2-aminopyridine is attached to the Pt through I, and not through N as in the case of the α-aminopyridine-Pt complexes. 2

7—ANALYTICAL CHEMISTRY

W. T. HALL

Preservation of solutions for use in chemical analysis (sodium hypochlorite, ammonium molybdate and soluble starch). Hidehiro Goto, Ryozi Takeno and Tadasi Ikeda. *J. Chem. Soc. Japan* **60**, 945–8(1939).—0.1 *N* NaClO obtained by leaching bleaching powder with Na_2CO_3 soln. can be kept without change in a dark bottle; only 0.2–0.7% decompn. results after 1 year. A soln. which is 5 *N* in HNO_3, 3 *N* in NH_4NO_3 and contains 2.5% com. NH_4 molybdate can be kept without decompn. for at least 3 years. To preserve the starch soln. used in iodometry, a little HgI, CS_2, HCl or salicylic acid should be added. 5

T. Katsurai

The application of electrodeless ring discharge in high-frequency magnetic field for the spectral analytical search for traces. E. Fenner. *Spectrochim. Acta* **1**, 164–7 (1939).—Traces of Cd in Se and of Hg in gases which were too small to be detected in conventional spark or arc spectra were recognized when samples were inclosed in a tube inserted in a solenoid of 6 turns fed by a high-frequency current of 6 m. wave length. In like manner traces of Se in other materials are revealed by the Se lines at 2164.3 and 2413.5 A. 6

W. F. Meggers

3,5-Dinitro-4-methylbenzazide as a reagent for the identification of amines. Peter P. T. Sah. *Rec. trav. chim.* **58**, 1008–12(1939)(in English).—The use of 3,5-dinitrobenzazide (I) was extended to the identification of amines. Fifty amines were tested and the characteristics of their condensation products with I were obtained. The method consisted of refluxing I with an equiv. of the amine in anhyd. toluene and allowing the soln. to remain in the cold overnight. Primary amines gave the best results while secondary gave some difficulty owing to their greater soly. in C_6H_6 and toluene. The use of ligroin for recrystn. in the latter case gave better results. 7

J. C. Lo Cicero

***m*-Nitrobenzazide as a reagent for the identification of phenols.** Peter P. T. Sah and Tsu-Fen Woo. *Rec. trav. chim.* **58**, 1013–17(1939)(in English).—*m-Nitrobenzazide* (I) which on heating gives the isocyanate was made to condense with 33 phenols in boiling ligroin giving the corresponding urethans the phys. properties of which, i. e., soly., crystal structure and m. p., were obtained. 8

J. C. Lo Cicero

Polarographic determination of aluminum in magnesium alloys. B. A. Heller and A. M. Zan'ko. *Zavodskaya Lab.* **8**, 1030–2(1939).—Dissolve a 0.2–0.5-g. sample in a min. excess of 2 *N* HCl, cool, add a soln. of bromophenol blue, neutralize carefully at first with milk of lime until the yellow color begins to change to yellow-green and then neutralize completely with a satd. soln. of $Ca(OH)_2$ to the bright green color of the reference soln. (buffer soln. with a pH of 3.3, colored with bromophenol blue). When artificial lighting is used, the end of the reaction is detd. by the change of the yellow-green color of the soln. to a brown-green coloration. The soln. is then dild. to 100 ml., poured into an electrolyzer, and polarographed, starting with 1.4 v. The milk of lime should be prepd. from thoroughly ground $CaO(Ca(OH)_2)$. The procedure lasts 20 min. and is applicable for detg. Al in Mg alloys contg. up to 10% Al. The errors ranged up to 5–6%. 9

B. Z. Kamich

Determination of small amounts of antimony in mercury ores. M. Ya. Shapiro. *Zavodskaya Lab.* **8**, 986–8(1939). —The procedure is suitable for detg. small amts. of Sb in Hg ores contg. Fe, As and Si. Heat a 1–2-g. sample in a Kjeldahl flask with 10–20 ml. concd. H_2SO_4 until the supernatant liquid becomes clear, transfer the contents to a 200-ml. flask, dil. to the mark with a soln. of 10% H_2SO_4 contg. 1% tartaric acid, and filter. A 10–20 ml. portion of the clear filtrate is retained for colorimetric tests. To a Nessler tube add in the order given 10 ml. of a 0.5% gelatin soln., 5 ml. of 10% KI soln., 1 ml. of 10% pyridine soln., 1 ml. of H_2SO_3 (1.3), 60 ml. of H_2SO_4 (1:3), and 10 or 20 ml. of the test soln. To another Nessler tube add these same solns. 10 or 20 ml. of 10% H_2SO_4, and enough of an Sb soln. to give the same coloration. The Sb soln. contains 0.1 mg. Sb per ml. The method is applicable for detg. 0.03–3% Sb in ores contg. up to 8% Hg, up to 10% Fe, and up to 5% As. The detn. requires 2.5 hrs. 10

B. Z. Kamich

Activation of zinc in the determination of small amounts of arsenic. K. B. Khait. *Lab. Prakt.* (U. S. S. R.) **14**, No. 8, 22–6(1939).—Min. amts. of $CuSO_4$ which cause no losses of As during the activation of Zn were not over 1.88 mg. of Cu per 2 g. of Zn. In such amts. $CuSO_4$ can be used as an activating substance and complete conversion into AsH_3 is accomplished. A $PtCl_4$ soln. cannot be used as an activator of Zn because (up to 90%) As is adsorbed by the spongy Pt which covers the surface of Zn. A fu-

sion of Zn with $MgCl_2$ followed by its granulation was found to be a good activating substance for Zn. Add 1–1.5 wt. % of anhydrous $MgCl_2$ to fused metallic Zn and pour the liquid mass into cold water. Such granulated Zn causes no losses of As in the analysis. Three plots, 4 tables and 6 references are given. W. R. Henn

Estimation of arsenic. Paul Nitsche. *Pharm. Zentralhalle* **80**, 701–6(1939).—Four procedures are described but for org. substances such as *must, wines, bones, hair,* parts of *cadavers,* etc., it is recommended to destroy org. matter in the wet way and then carry out a modification of the Gutzeit tests. Full details are given for detecting as little as 0.5 γ of As. A 5% soln. of $HgBr_2$ is recommended for impregnating the paper upon which the stain is to be produced and the generator is kept in a bath of cold water. W. O. E.

Note on the use of nephelometer for the routine determination of traces of arsenic by Bougault's method. Jacques Thuret. *Ann. fals.* **32**, 328–30(1939).—Bougault's method consists essentially in reducing oxygenated As compds. in HCl soln. by means of hypophosphorous acid. The resulting turbidity can be measured with the nephelometer by comparison with standard solns. treated similarly. The standards, however, are not stable, even if stabilized by the addn. of gum arabic, and must be prepd. daily. The following procedure gave turbidities which showed no change after 1 month: dissolve 2.5 g. borax in 150 cc. distd. H_2O, add 1 g. powd. rosin, heat 15–20 min. with const. stirring, continue stirring while allowing to cool, and dil. to obtain the desired series of turbidity standards. A. Papineau-Couture

Studies of gravimetric analysis by means of the thermobalance. XXI. Determination of calcium, lead and thorium as picrolonate and of phosphorus, palladium, columbium, zirconium, gold, beryllium, tantalum and silicon by the oxine method. Tosiyasu Kiba and Tadasi Ikeda. *J. Chem. Soc. Japan* **60**, 911–14(1939); cf. Goto, *C. A.* **28**, 4331⁹.—The proper temps. of drying as detd. by the thermobalance are: Ca picrolonate octahydrate < 40°, hemihydrate 150–75°, anhydride 200–30°; Pb picrolonate sesquihydrate < 140°, hemihydrate 220–60°; Th picrolonate < 35°, anhydride 160–80°; oxine phosphomolybdate dihydrate 115–35°; Pd oxine 120–40°; Cb_2O_5-oxine 110–30°; Zr oxine 115–50°; metallic Au > 700°; BeO > 880°; Ta_2O_5 > 450°; $SiO_2.12MoO_3$ 600–50°. **XXII. Determination of arsenic.** Yukito Yosida. *Ibid.* 915–17.—Proper drying temps. are: As_2S_3 < 200°, As_2S_5 < 130°, $MgNH_4AsO_4.6H_2O$ < 60°, $Mg_2As_2O_7$ 850–950°, Ag_3AsO_4 550–780°, $UO_2NH_4AsO_4.3.5H_2O$ < 60°, $UO_2NH_4AsO_4.H_2O$ 200–310°, $(UO_2)_2As_2O_7$ 620–80°, $BiAsO_4.0.5H_2O$ 160°, $BiAsO_4$ 450–550°. **XXIII. Determination of cobalt, copper, iron, vanadium, uranium, molybdenum, selenium, thorium and silicon.** Hisazi Kato, Hiraku Hosimya and Sigeharu Nakazima. *Ibid.* 1115–18.— The proper heating temps. for various compds. used in gravimetric detn. are: $CoNH_4PO_4.H_2O$ 105–70°, $Co_2P_2O_7$ > 600°, $CoSO_4$ 500–600°, Co_3O_4 800–900°, CuO 800–950°, Fe_2O_3 > 800°, V_2O_3 > 650°, U_3O_8 800–900°, Ag_2MoO_4 250–500°, $PbSeO_4$ < 280°, ThO > 780°, $SiO_2.12MoO_3$ 480–550°, SiO_2 > 900°. **XXIV. The rapid method of determining metals as complex compounds and the gravimetric evolution method by the use of various fluxes.** Kiyosi Tani and Harumi Hasimoto. *Ibid.* 1119–23.— The thermal decompn. of various complex salts of Cu, Ni, Co, Cd, Zn, Pb, Bi was studied with the thermobalance. The proper temp. for heating to const. wt. was detd. for each complex salt. The proper heating temps. for fluxes used in the evolution of gas were detd. **XXV. Determination of mercury.** Yukito Yosida. *Ibid.* 1124–6.— The proper heating temps. were detd. for various compds. of Hg. T. Katsurai

Determination of small amounts of cobalt in the presence of large amounts of iron. P. V. Faleev. *Zavodskaya Lab.* **8**, 381–9(1939).—Co in Cu-Ni ores contg. large amts. of Fe was detd. as follows: Heat a 1–10-g. sample with 10 ml. of concd. HCl until evolution of H_2S ceases, add 5 ml. HNO_3, evap. to dryness, and repeat evapns. with 5-ml. portions of HCl. Heat the residue with 5 ml. HCl, dil. with 50–60 ml. hot water, dissolve the salts, filter, neutralize the filtrate with potash, filter, and dissolve the ppt. in the min. amt. of 80% HOAc. To the soln. (not exceeding 100 ml.) add 7–8 ml. HOAc, and ppt. the Co as $K_3Co(NO_2)_6$. Allow to settle for 24 hrs. and filter. The ppt. contains only small amts. of Fe which are removed by dissolving and repptg. under the above conditions. Det. the Co by weighing the $K_3Co(NO_2)_6$. B. Z. Kamich

Determination of cobalt and nickel in "mixtures" and hard alloys (tungsten carbides). V. G. Shcherbakov. *Zavodskaya Lab.* **8**, 389–91(1939).—The following methods were used: (1) Calcine the sample to destroy carbides and oxidize the W and Co. Sep. the Co and Fe from the W by pptn. with NaOH. Dissolve the ppt. in HCl, ppt. the Fe with NH_3 filter and electrolyze the filtrate for Co. (2) Treat the sample with HF and follow this with dropwise addn. of HNO_3 to destroy carbides. Ppt. the Co and Fe with NaOH, add 2–3 ml. of 30% H_2O_2 or 0.5 g. NH_4 persulfate, and boil the ppt. and soln. for 10 min. Filter, dissolve the ppt. in HCl, ppt. the Fe with NH_3 and det. the Co in the filtrate by electrolysis. The method was also used for samples contg. Ni instead of Co, but in this case NH_4 persulfate was used as the oxidizer. B. Z. K.

Determination of gold in ores by the wet method. O. E. Zvyagintsev, V. A. Vorob'eva and S. K. Shabarin. *Zavodskaya Lab.* **8**, 909–10(1939).—The method is applicable to both sulfide and oxidized quartz ores. Sulfide ores are first treated with HNO_3, the Au is extd. with I_2 soln., then reduced and amalgamated with Hg. The amalgam is dissolved in HNO_3, the extd. Au is dissolved in aqua regia, and it is then detd. by the drop reaction on a filter paper impregnated with $HgNO_3$. The sensitivity of the method is 0.005 g./ton. B. Z. Kamich

Determination of iron in iron salts of organic acids containing phosphorus. C. F. Bickford, A. E. Jurist and W. G. Christiansen. *J. Am. Pharm. Assoc.* **28**, 1028–9 (1939).—The Fe is pptd. as sulfide in ammoniacal soln., dissolved in acid, the Fe^{++} oxidized, pptd. as $Fe(OH)_3$ and weighed as Fe_2O_3. Org. matter is usually destroyed first but in some cases it is unnecessary. Thus with Fe adenylate, $C_{10}H_{12}N_5O_7PFe$, contg. 13.93% Fe, the value 13.36–14.42% Fe was obtained after destruction of org. matter and 13.72–14.05% when analyzed directly. A. Papineau-Couture

Elimination of iron by means of cupferron in the colorimetric determination of lead by the dithizone method. Mme. M. L. Panouse-Pigeaud and H. Cheftel. *Ann. fals.* **32**, 296–301(1939); cf. *C. A.* **30**, 3849⁷.—In the detn. of Pb by the dithizone method, under certain conditions the interference of Fe cannot be overcome by the use of KCN. It has already been proposed to remove Fe with cupferron (Clifford, *C. A.* **32**, 5934⁸), but the excess of the latter remaining in the soln. interferes with the subsequent colorimetric detn. of Pb (also noted by Clifford in private communication to the authors). This is overcome by destroying the cupferron residue by heating. The method (technique described in detail) consists essentially in destroying org. matter by H_2SO_4-HNO_3-$HClO_4$, pptg. Fe with cupferron in an acid soln., extg. the ferric complex with $CHCl_3$, evapg. the aq. soln. (contg. all the Pb) to white fumes, taking up in water and extg. with dithizone in the usual manner. A. Papineau-Couture

Volumetric determination of lithium. I. T. Polyanichka. *Zavodskaya Lab.* **8**, 1052–4(1939).—The method depends on the conversion of Li^+, Na^+ and K^+ to normal carbonates by evapg. in the oxalic acid and heating the residue. In one portion the three carbonates are titrated with HCl to a methyl orange end point and in another portion the $Na_2CO_3 + K_2CO_3$ is detd. similarly after dissolving them in 50 ml. of EtOH which has been satd. with Li_2CO_3. B. Z. Kamich

The assay of mercury. J. Sandilands. *Analyst* **65**, 13–17(1940).—The proposed method consists in heating the sample with partly dehydrated HIO_3 which converts the Hg from ores or mercurials into HgI_2 which is made to condense in the cooled front end of the tube. The excess I_2 formed by decompn. of HIO_3 is then removed by treat-

ment with $Na_2S_2O_3$ and the excess of the thiosulfate, if an excess is used, by careful treatment with I_2 soln. The soln. of the HgI_2 is then made acid and HgS formed by introduction of H_2S. The ppt. is dried and weighed after filtering with a sintered glass crucible. W. T. H.

Determination of small amounts of nickel. V. M. Peshkova. *Zavodskaya Lab.* **8**, 921–5(1939).—Small amts. of Ni (not less than 0.2 mg.) in the presence of large amts. of Co can be detd. gravimetrically with dimethylglyoxime. Smaller amts. of Ni should be detd. colorimetrically. If the colorimetric detn. of Ni involves its sepn. beforehand, then the ppt. of the glyoxime Ni salt is dissolved in a very little 2–3 *N* HCl and the soln. is neutralized with ammonia which is added in slight excess. B. Z. Kamich

Photoelectric method of determining silicon in cast irons and steels. A. L. Davydov, B. E. Reznik and Z. M. Vaisberg. *Zavodskaya Lab.* **8**, 1033–8(1939).—Si in cast irons and steels contg. P was detd. colorimetrically using Si-Mo blue complex. The detns. were made with and without sepn. of the Fe. Both methods gave equal accuracy. For steels contg. 0.1–0.8% Si the error was 3–5% and for cast irons contg. 0.5–4% Si the max. error was 2–5%. The method is more accurate and reliable than that which is based on the yellow Si-Mo complex. B. Z. Kamich

Determination of vanadium in cast irons and slags with the aid of *p*-phenylaminobenzoic acid. V. V. Stepin. *Zavodskaya Lab.* **8**, 1039–40(1939). - *p*-Phenylaminobenzoic acid was successfully used as an indicator instead of *o*-phenanthroline in detg. V in cast irons and slags. The indicator is sensitive enough for the detection of 0.5 γ V. B. Z. Kamich

Electrophotometric determination of fluorine in aluminum salts. M. M. Raĭnes and A. I. Krupkin. *Zavodskaya Lab.* **8**, 399–404(1939).– As little as 0.01–2.0 mg. of F in alums and $Al_2(SO_4)_3$ was detd. colorimetrically with the photoelec. cell. Two methods were used. A $ZrCl_4$ soln. was colored with a salt of alizarinsulfonic acid and the bleaching effect of F^- measured or the color was produced from Ti^{++++} and H_2O_2 and bleached. The F^- was distd. from $Al_2(SO_4)_3$ by the Tananaev method (cf. *C. A.* **29**, 1741[7]) but FeSi was used in place of CO_2. B. Z. Kamich

Preliminary investigation of the determination of fluorine in lime. C. J. Kochler. *Am. Soc. Testing Materials, Symposium on Lime* **1939**, 83–7(1940).—The use of fluoride as preservative in *foods* and in *treating* public *water supplies* makes the detn. of F in lime important. Existing methods which might be applied are reviewed critically; a procedure of steam distg. H_2SiF_6 from a 20-g. sample with 100 ml. 60% $HClO_4$ and glass beads, and titrating successive 80-ml. portions of condensate mixed with an equal vol. of EtOH and buffered by NaOH + $CH_2ClCOOH$, in the presence of Alizarine S indicator, with standard $Th(NO_3)_4$ soln., is described. Since many successive portions of distillate are necessary before the removal of F is complete, a math. treatment of the data obtained from the second and third portions, to arrive at the probable total of the series, was attempted without very encouraging results when the amts. to be recovered varied widely. The study is to be continued. Thirteen references. C. J. Schollenberger

Polarographic and photocolorimetric determination of oxygen in water. A. M. Zan'ko, F. A. Manusova and A. D. Nikitin. *Zavodskaya Lab.* **8**, 937–40(1939).—A comparative study was made of the polarographic and colorimetric (with NH_3-Cu complex) methods for detg. O in water. Both methods give comparable results to 1 ml. When the O content is 1 to 0.1 mg. the use of the polarographic method involves various difficulties including the effect of temp., contact of the sample with the O of the air, and small height of the O waves. A colorimetric method based on the reaction of *o*-tolidine on Cu can be used if the O content is below 1 mg./l. (down to 0.01 mg./l.). In this method a part of the NH_3 soln. of Cu is evapd. until NH_4Cl begins to crystallize, the soln. is cooled, the crystals dissolved, 1–2 ml. of 0.3% gelatin and 0.5–1 ml. of 1% tolidine are added, the soln. is dild. with a satd. soln. of NH_4Cl, and the Cu is detd. colorimetrically. B. Z. Kamich

The determination and detection of small quantities of phosphorus by the quinine molybdate complex. John A. Street. *Australian Chem. Inst. J. & Proc.* **6**, 395–9(1939).—A new reagent, quinine molybdate, for the microdetection of P and its application to the rapid detn. of minute amts. of P contained in purified C_2H_2 are described. The method takes advantage of the fact that quinine can combine with the phosphomolybdate ion, forming an exceedingly voluminous ppt. which can be easily centrifuged and measured. Take 2–5 ml. of the soln. contg. about 0.1–0.3 mg. of P in a centrifuge tube and add 2 or 3 ml. of quinine molybdate reagent. After heating in boiling water for 5 min. place the tube in the centrifuge together with a similar tube contg. a standard soln. of phosphate which has been treated in the same way. Centrifuge these 2 solns. and measure their resp. vols. Rapid estn. within 5% accuracy is possible. In order to obtain such an accuracy in detg. the phosphine in crude acetylene contg. 0.01–0.03% phosphine, special tubes for the centrifuge were designed. The reagent consists of: (*a*) Ammonium molybdate soln. prepared according to Noyes (*Qualitative Chemical Analysis*); (*b*) 6 *N* HNO_3; (*c*) 20% quinine nitrate. Standard 0.002 *N* phosphate solns. were used for cylinder gas analysis and 0.02 *N* for crude gas. To prep. quinine nitrate, dissolve 20 g. of quinine dihydrochloride in 150 ml. of water, heat the soln. to boiling and add an excess of $(NH_4)_2CO_3$ soln. Filter and wash the ppt. Dissolve it in 50 ml. of 6 *N* HNO_3 and dil. to 100 ml. with water. A sensitivity of 0.003 in one drop is claimed with a practical limit of 0.01 per drop. The application of the method to the detn. of P in iron and steel is suggested. R. S.

Determination of phosphorus and its halides. O. D. Khalizova. *Zavodskaya Lab.* **8**, 940–3(1939).—Yellow P, $POCl_3$, PCl_3, HCl and Cl_2 in air are detd. with the aid of 4 absorbing systems: (1) The Cl and $POCl_3$ are absorbed in water, the Cl^- being detd. nephelometrically in 1/2 of the soln. and the H_3PO_4 colorimetrically in the second half by the Denigès method. (2) Absorption in 0.1 *N* $AgNO_3$ to det. the elementary chlorine nephelometrically. (3) Absorption in Br water followed by evapn. of the soln. and detn. of total P by the Denigès method. (4) Absorption in $AgNO_3$ soln., filtration through a Schott filter, and washing of the ppt. with 3% HNO_3 to dissolve any ppt. formed from PCl_3. The Ag_3P is then oxidized with Br water and the P is detd. by the Denigès method. From the above mentioned detns. it is possible to calc. the P, $POCl_3$, PCl_3, HCl and Cl_2 in the air. B. Z. Kamich

Polarographic analysis of white metals. Danilo Cozzi. *Ann. chim. applicata* **29**, 442–7(1939).—Details of methods for the polarographic analysis of alloys contg. Pb, Sn, Sb, Cu and Zn are given. A. W. Contieri

Polarographic determination of the alloying constituents in alloy steels. M. v. Stackelberg, P. Klinger, W. Koch and E. Krath. *Arch. Eisenhüttenw.* **13**, 249–62(1939).—See *C. A.* **33**, 8523[1]. M. Hartenheim

Quantitative spectral analysis of "hydronalium" alloys. K. E. Mann. *Spectrochim. Acta* **1**, 108–16(1939).—Zeiss app. and procedure are used in making detns. of Mg, Si, Mn, Fe and Cu in hydronalium alloys contg. 2–10 % Mg 0.8–1.2% Si, 0.2–0.3% Mn and Fe and Cu as impurities. Av. errors range from 0.6 to 4.8%. W. F. Meggers

Spectral analysis of magnesium alloys. K. A. Sukhenko and L. A. Alifanov. *Zavodskaya Lab.* **8**, 966–8(1939).—The following detns. can be made: Na from the lines Na 5889 A. and Fe 5914 A. for concns. of 0.005 to 0.02%, Ca from the lines Ca II 3933.6 A. and Fe I 3930 A. for concns. of 0.005 to 0.15%. For Fe the line Fe II 2382 A. was used and also Cu 2403 A. In detg. Fe the const. electrode was made of electrolytic Cu. The last pair of lines made it possible to work in the concn. range of 0.01 to 0.07%. B. Z. Kamich

Origin of the colors obtained in testing for alkali chlorates by the dry method. Armando D. del Boca. *Anales farm. bioquím.* (Buenos Aires) **10**, 88–108(1939).—When fused $KClO_3$ is partially reduced by wood charcoal in the presence of a trace of Fe compd. the residual salt mixt. is

purple or red because of formation of perferrate, K_2FeO_4. Continued heating at high temp. converts the K_2FeO_4 to green ferrate, K_2FeO_3. L. E. Gilson

Determination of barium sulfate in the lead plates of batteries. E. T. Vil'yamovich. *Zavodskaya Lab.* **8**, 1057–9(1939).—The $BaSO_4$ is converted into $BaCO_3$ by extensive leaching with Na_2CO_3, the Pb is then pptd. as Pb(OH)Br with KBr soln. in the presence of a slight excess of NH_3, the soln. is filtered, and the $BaSO_4$ is repptd. and weighed. Time required for a detn. is 7–9 hrs. and the error did not exceed 1.12%. B. Z. Kamich

Rapid determination of sulfate in the presence of large amounts of chromate. A. A. Babalova, L. E. Sabinina and P. S. Pil'nik. *Zavodskaya Lab.* **8**, 911–13(1939).—The method is applicable to solns. where the sulfate content is approx. known. A definite amt. of titrated $BaCl_2$ soln. in alc. is added to the unknown soln., the ppt. of $BaSO_4$ and $BaCrO_4$ is filtered through a Schott filter, the $BaCrO_4$ is dissolved in HCl, and the CrO_4 is detd. by a conventional method. The sulfate is calcd. from the amt. of $BaCl_2$ added and $BaCrO_4$ formed. Analysis takes 2–2.5 hrs. B. Z. Kamich

Automatic device for controlling the change from chromate to bichromate ions. S. S. Orlov. *Zavodskaya Lab.* **8**, 913–16(1939).—A description is given of an automatic signalling device for controlling the reaction $2CrO_4^{--} + 2H^+ = 2HCrO_4^- = Cr_2O_7^{--} + H_2O$. The set-up includes a pair of PbO_2-covered Pt gauze electrodes. One of the half-cells contains a standard soln. of $NaHCrO_4$ which contacts the soln. to be titrated by means of a porous glass plate. B. Z. Kamich

Iodometric determination of sulfites. M. V. Gapchenko. *Zavodskaya Lab.* **8**, 1064–5(1939).—To the test soln. add 2 *N* NaOH and an excess of 0.1 *N* I_2 soln., and after acidifying with HCl titrate with 0.1 *N* thiosulfate. The addn. of the sulfite to the I_2 or the I_2 to the sulfite had no perceptible influence on the results. The presence of NaOH impedes the oxidation of the sulfites by the oxygen of the air. B. Z. Kamich

Detection of gases used in warfare. A. Gigon and M. Noverraz. *Schweiz. med. Wochschr.* **69**, 859–60(1939).—An to be tested for gases used in chem. warfare is bubbled by means of an aspirating pump through a tube contg. 2 cc. of an alc.-H_2O soln. to which bromophenol blue has been added. The acid reaction of the war gas changes the color of the indicator. The method is a modification of Kling's technique (cf. *C. A.* **32**, 8034[8]). With chloropicrin as an example, it was found that (with breathing at a rate of 21. per min.) a concn. which produced a change in color in 1½ min. would be harmless even after prolonged inspiration of the gas, whereas a concn. which produced a color change in 1 to 2 sec. would be lethal after 10-min. respiration. Maurice M. Rath

Spectral analysis of solutions and minerals. A. K. Rusanov and V. M. Alekseeva. *Zavodskaya Lab.* **8**, 963–5(1939).—The intensities of the lines Na 5890.0 and 5895.9 A.—Cr 5787.98 A. and Li 6103.59 A.—Mo 6030.06 A. were measured to det. Na and Li. With a 2-ml. sample the Na can be detd. down to a concn. of 0.001% and Li to 0.003%. These elements can be detd. in the presence of other alk. metals with a probable error of ±4.6% for Li within the concn. range of 0.001–0.2% and ±4.3% for Na for the concn. range of 0.001–0.1%. B. Z. K.

Rapid determination of carbon dioxide in ammonium salts containing carbon. G. Zavarov. *Zavodskaya Lab.* **8**, 1061–3(1939).—The Winkler method for detg. carbonates is modified to make it applicable to solns. contg. NH_4 salts. The NH_4 group is removed with formalin and an excess of NaOH and the soln. is then analyzed by the Winkler method; the carbonate is pptd. with $BaCl_2$ and the excess NaOH is titrated with HCl. The procedure requires only 10–12 min. and is applicable to solns. contg. urea. Corrections should be made for the acidity of the formalin and for the CO_2 in the alkali. B. Z. Kamich

Galvanometric titration of strong acids. A. P. Sergeev. *Zavodskaya Lab.* **8**, 907–9(1939); cf. *C. A.* **32**, 4457[9].—The method of galvanometric titration was applied to strong acids. The control soln. used was neutral. The acids titrated were 0.2 and 0.001 *N* HCl and 0.2 *N* HBr. The results compare favorably with those obtained by titrating in the presence of phenolphthalein. B. Z. K.

Biochemical method of large-scale extraction of prussic acid in sorghum for breeding purposes. M. I. Smirnova and G. A. Katanskaya. *Compt. rend. acad. sci. U. R. S. S.* **24**, 592–5(1939)(in English).—One-g. aliquot of leaves was triturated with glass and a few drops of toluene in a porcelain mortar. The mass obtained was placed in a graduated flask and made up to 100 cc. with H_2O. The flask was corked tightly, allowed to stand at room temp. for 12 hrs. during which time the extn. and splitting up of the glucoside were taking place and the HCN was partly liberated. Then the contents of the flask were stirred and 5 cc. of the suspension was drawn off into a conical flask 60 mm. high and 20 mm. wide at the bottom. The flask was tightly closed with a cork which had a strip of picrate paper (4 mm. × 30 mm.) attached by means of paraffin. It was kept in the dark at room temp. for 48 hrs. Two flasks were loaded with each of the samples. The intensity of the color assumed by the paper was used to est. the HCN content by comparison with the results obtained from standard solns. contg. KCN and tartaric acid. A. H. Krappe

Determination of hippuric acid by colorimetry. Georges Denigès. *Compt. rend.* **209**, 972–4(1939); cf. *ibid.* **107**, 163(1888).—The method, specially suited for detg. hippuric in the presence of benzoic acid, depends on the formation of the red cochineal-like substance by the action of NaOBr on hippuric acid; a similar reaction does not take place with benzoic acid. To 5 cc. of a soln. to be tested, on a boiling water bath, add 2 cc. of NaOBr. aq., recently prepd. by adding 20 cc. H_2O and 1 cc. Br to 10 cc. of a 30% soln. of NaOH. Stir the mixt. for 30 sec. and then add 1 cc. $CHCl_3$ or 1.5 cc. Et_2O which dissolves the red substance. Remove the colored soln. and det. the hippuric acid by the depth of color. The method is sensitive to 0.5 g./l. The NaOBr can be replaced by NaOCl but the color is more yellow and the test is less sensitive. C. A. Silberrad

Determination of silicic acid in aluminate solutions containing chromium and fluorine. K. A. Vasil'ev and O. D. Barinova. *Zavodskaya Lab.* **8**, 916–20(1939).—Acidify the sample with 20% H_2SO_4, heat to dissolve, and cool. If Cr is present it should be reduced. Then add 20–40 ml. ammonium molybdate, dil. to 300 ml., stir, and let stand for 15 min. Add 40 ml. HCl (1:1) and an excess of a titrated 1.2% soln. of 8-hydroxyquinoline, stopper and heat for 10 min. at 60–70° with periodic shaking. Cool, dil. to 500 ml. and stir. Filter, discard the first portions, and to a 100-ml. portion add 50 ml. H_2O, 60 ml. HCl (1:1) and 30 ml. of 80% oxalic acid, and titrate with 0.1 *N* bromide-bromate soln. in the presence of methyl red. B. Z. K.

Conductometric titration of sulfuric acid in a mixture of sulfuric and nitric acids. K. K. Savich. *Zavodskaya Lab.* **8**, 1059–61(1939).—The H_2SO_4 in mixts. of HNO_3 and H_2SO_4 was detd. by conductometric titration with benzidine-HCl after the mixt. had been previously neutralized with strong alkali. The elec. concd. decreases until all the H_2SO_4 is attached to the benzidine whereupon it makes a sudden jump. Best results are obtained when the HNO_3 and the H_2SO_4 are about 0.1 *N*. The benzidine-HCl soln. should be about 1%. Pt electrodes 1 sq. cm. and 5–6 mm. apart are convenient. During titration the electrodes become covered with benzidine hydrosulfate. B. Z. Kamich

Detection and determination of ortho-, pyro- and metaphosphate ions in their mixtures. B. Wurzschmitt and W. Schuhknecht. *Angew. Chem.* **52**, 711–15(1939).—A qual. method for *o-, pyro-, hexa-* and trimetaphosphate was developed on the basis of known reactions. The titrimetric detn. of pyrophosphate of Brizke and Dragunow was checked and improved by modifications. The method for detn. of phosphate ions in mixts. makes use of the selective extn. of phosphomolybdic acid (from *o*-H_3PO_4 and $(NH_4)_2MoO_4$) by means of org. solvents. The pyro-and meta-acid are not extractible. Total H_3PO_4 is detd. by the method of Lorenz and together with the above methods

permits the calcn. of the individual acids. Exptl. data and 6 references are given. Karl Kammermeyer

Microchemical determination of magnesium. P. Vukulov. *Zavodskaya Lab.* **8**, 494–5(1939).—The method is based on the vol. of HCl required to dissolve the $Mg(OH)_2$ ppt. First, ppt. the $Mg(OH)_2$ with excess 0.1 *N* NaOH, boil the soln. for 3 min., dil. to 100 ml. with water, filter, and titrate the filtrate with 0.1 *N* HCl, using Congo red indicator to det. approx. NaOH used to ppt. the Mg. To a portion of the test soln. corresponding to 1.1–1.2 ml. of 0.1 *N* NaOH, add NaOH in excess (0.1–0.2 ml.), 1 ml. distd. water, and 1 drop of Congo red, heat carefully to boiling, keep in boiling water for 3 min., and centrifuge. Neutralize the excess NaOH in the supernatant soln. with 0.1 *N* HCl, mix the $Mg(OH)_2$ ppt. with small amts. of 0.1 *N* HCl until a blue color is produced, heat the soln., keep in boiling water, and add more HCl to dissolve the ppt. completely. Titrate the excess HCl with 0.1 *N* NaOH. Any free acid or NH_4 salt in the soln. to be tested should be removed by titration to a pH of 3–5.2 and by gentle ignition. Differences between exptl. and actual values ranged from 0.000005 to 0.00003 mg./ml. soln. B. Z. Kamich

The use of perchloric acid in the digestion of plant materials. C. S. Piper. *Australian Chem. Inst. J. & Proc.* **6**, 421–7(1939); cf. *C. A.* **32**, 1608⁸.—HCl does not ext. completely the Mn, Fe and Cu from the ash of plant materials even when H_2SO_4 is used during the ashing process. The following digestion procedure makes treatment of the SiO_2 with HF unnecessary (in the detn. of Mn, Ca, Mg, Cu, Fe, phosphoric acid, etc.): To 1–5 g. of the plant material, dried 16–18 hrs. at 105°, add 4 ml. $HClO_4$ (sp. gr. 1.54) and 15–30 ml. HNO_3 (sp. gr. 1.42). Heat gently 3–5 min., and after the initial reaction has subsided, reduce to a vol. of 7–10 ml. (further reduction without addn. of H_2SO_4 often results in explosion); add 2–4 ml. concd. H_2SO_4 and reduce until dense fumes have been evolved for 5–10 min. Heat 2–3 min. further at a high heat. Certain detns. such as the estn. of Cu with diphenylthiocarbazone require 10–15 min. boiling after diln. of the digestion mixt. Solns. with pH values greater than 3–4 give interfering cherry-red colors with diphenylthiocarbazone in the detn. of Zn. George Ayers

Detection of urea in urine stains on carpets. G. N. Gee. *Analyst* **65**, 25–6(1940).—Expts. on carpets stained with human and animal urine showed that procedures depending upon the evolution of NH_3, the formation of biuret, color tests, liberation of N_2, etc., were unsatisfactory because of interference by the wool. Better results were obtained by extn. with EtOH and acetone followed by evapn. of the ext. and identification of the urea under the microscope. W. T. H.

Potentiometric titration of organic precipitates. VI. Determination of potassium, rubidium and cesium precipitated as their dipicrylamine complexes. Tosiyasu Kiba. *J. Chem. Soc. Japan* **60**, 1073–80(1939); cf. *C. A.* **32**, 5726².—By means of dipicrylamine, K, Rb and CS are pptd. The 6 nitro groups in the ppt. are titrated with Ti^{+++} soln. and the end point is detd. potentiometrically. T. Katsurai

Determination of allyl alcohol in the air. N. B. Baranov. *Zavodskaya Lab.* **8**, 931–2(1939).—Pass a definite vol. of air contg. the allyl alc. through 3 Petri tubes each contg. 15 ml. water, at a speed of 51./hr. The allyl alc. is usually absorbed completely in the first tube. Transfer the alc. soln. to an Erlenmeyer flask, add a definite vol. (10–25 ml.) of a bromide-bromate soln., then 40 ml. of a 10% H_2SO_4 soln., and allow the stoppered mixt. to stand for 15 min. Add 3 ml. of 1% KI soln., stopper, and after 15 min. titrate with 0.01 *N* $Na_2S_2O_3$. For 2 mg. allyl alc. the errors did not exceed 2% and for 0.1 mg. the error reached as high as 10%. The presence of MeOH in the air in amts. equal to that of the allyl alc. did not affect the detns., while an equal amt. of acetone increased the results slightly. Formaldehyde also increased the results slightly, but the errors were not higher than the exptl. deviations. B. Z. Kamich

Determination of acetone. Melvin W. Green. *J. Am. Pharm. Assoc.* **29**, 33–5(1940).—Of the 3 general methods for assaying Me_2CO (Hg-complex, oxime, and CHI_3 methods), the Hg method gives the lowest, the oxime method gives the highest, and both give variable results. The CHI_3 method gives more consistent values but they are too high, probably because a secondary reaction takes place. Ten rather than 5 equivs. of I are involved. A. Papineau-Couture

Analysis of acetylene-ethylene gas mixtures. Ya. T. Eidus. *Zavodskaya Lab.* **8**, 948–50(1939).—The C_2H_4 in C_2H_2 + C_2H_4 mixts. was detd. by absorbing the C_2H_2 in a Hempel tube contg. over 100 ml. of a soln. contg. 20 g. $Hg(CN)_2$ in 100 ml. of 2 *N* NaOH. Absorption of C_2H_2 was practically complete after 3 min. shaking while the vol. loss of C_2H_4 was 1.8%. The absorption of the C_2H_4 was 2.5–3 times slower than in an ammoniacal 2% soln. of $AgNO_3$. Diln. of the C_2H_2 with air or with an inert gas decreased the absorption of C_2H_2 during a 3-min. period. B. Z. Kamich

Potentiometric titration of glucose with alkaline tartrate solutions of copper, including Fehling's solution. H. T. S. Britton. *Analyst* **65**, 18–24(1940).—A series of potentiometric titrations gave results which were in agreement with the values obtained by Lane and Eynon, *C. A.* **17**, 1400, with methylene blue. The precise ratio of Na tartrate to $CuSO_4$ is not a matter of great importance although variations in the oxidizing effect of Cu on glucose are influenced by the alkali content. Na tartrate is just as good as Rochelle salt. The ease with which Cu_2O is reoxidized by the air in the vicinity of the end point shows that any attempt to use an outside indicator will lead to unreliable results. Detailed directions are given for carrying out the detn. W. T. H.

Isodihydroxycholenic acid. Specificity of the Hammersten cholic acid reaction. Kazumi Yamasaki, Kumao Takahasi and Chai Heung Kim. *J. Biochem.* (Japan) **30**, 239–46(1939).—Three isomeric dihydroxycholenic acids (3,12-dihydroxy-$\Delta^{7,8}$-cholenic, 3,12-dihydroxy-$\Delta^{8,14}$-cholenic and 3,12-dihydroxy-$\Delta^{8,9}$-cholenic) are formed from cholic acid in concd. HCl. The last (isodihydroxycholenic) is associated with the violet Hammersten color reaction. The isodihydroxycholenic acid is formed also when cholic acid is boiled in AcOH with $ZnCl_2$, $SbCl_3$ or $FeCl_3$. The original Yamasaki modification of the Hammersten reaction has certain disadvantages which are eliminated by the following procedure. A very small amt. of the test material is dissolved by warming in AcOH. Concd. HCl (3–4 drops) is added and the soln. is boiled carefully in a water bath until a slightly turbid soln. results. Left at room temp., the color changes from yellow to violet. The reaction is very specific. The color is affected by the side chain of the bile acid mol. The reaction is pos. for bile acids which contain a carboxyl on C_3 in addn. to 2 secondary alc. groups at C_7 and C_{12} as well as for 3-keto-7,12-dioxycholic acid. Bile acids like 7,12-dihydroxycholanic containing a secondary alc. or keto group at C_3 do not give the Hammersten reaction S. Morgulis

Detection and estimation of benzedrine. Edward T. Illing. *Analyst* **65**, 3–7(1940).—Benzedrine, or β-aminopropylbenzene, $C_{19}H_{13}N$, is allied to ephedrine and adrenaline. It diminishes gastro-intestinal activity, interferes with sleep and may cause pronounced psychological changes. It tends to abolish fatigue. A case of acute aplastic anemia followed the ingestion of 190 mg. in 19 days. Severe cardiovascular collapse resulted but the patient recovered. In the case of a sudden death due to hemorrhage in the cranium, an attempt was made to prove the presence of benzedrine in the viscera. Benzedrine is a liquid, slightly sol. in water, more sol. in EtOH and readily dissolved by acids, Et_2O, amyl, alc., EtOAc and $CHCl_3$. It is entirely volatile at 100° and appreciable loss results at lower temps. Benzedrine gives the general reactions for alkaloids. It is best detected by a modified Mohler test as was recommended for the detection of benzoic acid (cf. *C. A.* **26**, 2942). A purple color is obtained. A fairly stable color results if the following soln. is used as diluent. Take 40 ml. water contg. 2 g. KNO_3, add 20 ml. of concd. H_2SO_4 and then while cooling add 200

ml. of 7.5 *N* NH_4OH and 40 ml. of water contg. 0.8 g. of $NH_2OH.HCl$. As a rule it is convenient to dil. the final 15 ml. of test soln. to 50 ml. with the above diluent. 2–3 mg. of benzedrine in 50 ml. of soln. is convenient for matching the color obtained in the test. The benzedrine can be sepd. from viscera by the Stas-Otto process and the benzedrine extd. from the alk. soln. with $CHCl_3$. The acetate is appreciably volatile so that if acidification is required at any stage, tartaric acid is recommended. It is advisable to ext. a portion of the $CHCl_3$ ext. with HCl soln. to prove the presence or absence of benzedrine. The benzedrine salt can be treated with water and NaOH and the benzedrine distd. off in dil. HCl soln. after which the color test can be applied. The benzedrine content of medicinal tablets was detd. by 3 methods and satisfactory values obtained by the distn. procedure. W. T. H.

Examination and determination of 2-methyl-1,4-naphthoquinone. J. L. Pinder and J. H. Singer. *Analyst* **65**, 713(1940).—Samples should be tested by the m. p. The pure product m. at 106° but the lemon-yellow to light brown decompn. product has a m. p. of 235° and the methylnaphthalene, from which the methylnaphthaquinone is usually prepd. by oxidation with CrO_3, m. at 32°. The quinone can be estd. by means of its absorption spectrum. A satisfactory chem. assay can be based on the reduction to hydroquinone by means of $TiCl_3$ with the end point detd. by an internal oxidation-reduction indicator. Weigh out 0.2 g. of the sample, dissolve it in 10 ml. of MeOH and 15 ml. of AcOH. Add to the soln. 4 g. of Na_2CO_3 and 25 ml. of a 10% aq. Rochelle salt soln. Titrate with 0.1 *N* $TiCl_3$ with K indigosulfonate as indicator. A suitable colorimetric test can be carried out as follows: To 1–5 ml. of alc. soln. contg. 0.4–0.8 g. of the quinone, add 3 ml. of a mixt. of equal vol. MeOH and concd. NH_4OH soln. Add 3–5 drops of $NC.CH_2.CO_2Et$ and allow the mixt. to stand exactly 30 sec. Add 5 ml. of 6 *N* KOH soln., mix and allow to stand 15 min. out of sunlight. Dil. to 50 ml. and measure the absorption in the Hilger (Spekker) absorptiometer with a light blue No. 6 filter interposed. W. T. H.

Bromatometric determination of antipyrines. V. Madis. *Österr. Chem.-Ztg.* **42**, 290–3(1939).—The various methods employing I_2 and picric acid solns. for the analytical detn. of antipyrines are discussed. M. suggests a method using $KBrO_3$ soln. in the presence of $AuCl_3$ as indicator. The analysis is carried out as follows: Dilute a neutral antipyrine soln. to 40 cc. with H_2O and then add 10 cc. of 2 *N* HCl, 1 g. KBr and 1 cc. of 0.1% $AuCl_3$. Heat the mixt. to 40–45° and titrate with 0.1 *N* $KBrO_3$ soln. until a permanent yellow color results, which is the end point of the titration. The Br_2 freed during the titration adds on to the double bond of the antipyrine. The action of the indicator is as follows: The $AuCl_3$ is converted by KBr into $K[AuBr_4]$, which has an intense yellow color, but is immediately reduced by antipyrine to colorless $K[AuBr_2]$. A slight excess of Br_2 oxidizes the latter to a yellow complex of trivalent auribromide, the formation of which serves as the end point of the titration. The results obtained by this method are compared with those from Kolthoff's iodometric method. The method is applicable to the detn. of antipyrines in the presence of salts together with which it is usually prescribed. Antifebrin, caffeine, caffeine salts, phenacetin and salicylic acid do not interfere with the test, but the method cannot be used if pyramidon, quinine or codeine salts are present. E. J. Mahler

Resorbed feldspar in a basalt flow. Carl Fries, Jr. *Am. Mineral.* **24**, 782–90(1939).—The basalt appears to have picked up some andesine, partially resorbed it, and then pptd. more calcic plagioclase, preserving the andesine remnants as cores. C. H. Hale

The characteristics of quartz veins of Verkhnyaya Selemdzha. G. P. Volarovich. *Mém. soc. russe minéral.* **67**, No. 1, 133–9(1938); *Khim. Referat. Zhur.* **2**, No. 4, 38(1939).—Quartz veins of 2 different ages are described. The older veins form a net of lenses which have a distinct borderline with the contg. rocks and no sign of metasomatosis. Sericite, muscovite, chlorite, the carbonates of Ca and Fe and rare crystals of pyrite are assocd. with the quartz. No Au was found. The new quartz formations are in the form of irregular, branching veins. In contrast to the older formations a metasomatosis of the xenolites of the contg. rocks is observed. Assocd. minerals are calcite, siderite, sericite, chlorite, orthoclase, sagenite, arsenopyrite, scheelite, antimonite, galenas, pyrite, sphalerite and chalcopyrite. The young quartz veins contain Au. W. R. Henn

The volcanic chain of western Cameroons. Bernard Gèze. *Compt. rend. soc. géol. France* **1939**, 219–20.—The lavas of Mt. Camerun vary from limburgites to labradorites, with occasionally some scattered trachyte. Little Mt. Camerun (Etinde) consists of rocks rich in leucite and nephelite—*etindite*. Further N. N. E. Mts. Manenguba and Bambuto consist of trachyte, andesite and basalt, the older parts of which, as also those of Etinde, are in places lateritized. C. A. Silberrad

Granite pegmatites of the Mt. Antero region, Colorado. Geo. Switzer. *Am. Mineral.* **24**, 791–809(1939).—Numerous Be-rich pegmatites and veins occur in a granite stock near Mt. Antero. The temp. apparently ranged from approx. 600° as shown by formation of low-quartz as the 3rd mineral (after microcline and beryl) of the pegmatite, to less than 200° as shown by the formation of fluorite after adularia in the hydrothermal veins. S. describes twinned octahedra of fluorite and gives a new angle table for bertrandite. C. H. Hale

The breakdown of the molecules in magma as a factor in its differentiation. Yu. A. Bilibin. *Compt. rend. acad. sci. U. R. S. S.* **24**, 783–5(1939) (in French).—The simplification of the mols. in the course of their breakdown in the magma can be reduced to 2 chief types: loss of a certain quantity of Si and breakdown of the mols. of the feldspar type into simpler complexes. The breakdown of the mols. affects the differentiation of the magma and its products in 2 ways: (1) some constituents of the mols. may be eliminated in the initial stages of crystn. and (2) in the deep magmatic centers at high temps. the breakdown of the mols. occurs prior to crystn. At the cooling of the marginal layers, an assocn. of certain mols. follows under the following conditions: the cooling rates must lie within certain limits, the breakdown temp. in the compd. must lie within the temp. limits of the magmatic center that is cooling and the diffusion velocities of the different constituents of the decompd. mols. must be sufficiently different. A. H. Krappe

Crystallization in the magmatic rocks of Persia. Emanuel Christa. *Mineralog. petrog. Mitt.* **51**, 172–260(1939).—Detailed petrographic data on the lavas which are characterized by alkali feldspars with a discussion of miscibility in the system albite–orthoclase–anorthite. An analysis of trachyte is included. J. F. Schairer

Petrographic observations on the rocks from Persia collected by A. Gabriel. A. M. Sedlacek. *Mineralog. petrog. Mitt.* **51**, 261–93(1939).—Microscopic data on plutonites and metamorphic rocks from the deserts of eastern Persia. J. F. Schairer

The eruptive rocks from Lainzer Tiergarten in Vienna. Alexander Kohler and Arthur Marchet. *Mineralog. petrog. Mitt.* **51**, 102–40(1939).—Two series of extrusive volcanic rocks are described including many basic tuffs and a contact rock. J. F. Schairer

Metataxis and metablastesis in the migmatites of the northwestern Thuringian Forest. Werner Koch. *Mineralog. petrog. Mitt.* **51**, 1–101(1939).—Ortho- and para-rocks of many different mineral facies occur in Ruhlaer Sattel. The petrography of their alteration to migmatites is described. The relation of the migmatites to hybrid granites and palingenetic diorites is discussed. A chem. analysis of diorite is included. J. F. Schairer

Geochemical investigations of volcanoes in Japan. XIX. The randon content of mineral springs of Yahiko-Kakuda district. 1. Iwazi Iwasaki. *J. Chem. Soc. Japan* **60**, 999–1004(1939); cf. *C. A.* **33**, 8536[6].—The results of the detn. of the Rn contents in 20 hot springs in the Yahiko-Kakuda district are given. **XX. The influence of rain water on the density of the water from a fumarole. 1.** Sinya Oana. *Ibid.* 1005–7.—The vapor from the Ioyama, Hakone is condensed and its d. is detd. The d., in dry season, is found to be greater than that of tap water by 1.9 γ. When it rains the d. becomes smaller owing to diln. by rain water. From the results of the d. detn. the percentage compn. of the condensed vapor can be estd. **XXI. Density of mineral waters in the vicinity of Komagatake, Akita prefecture.** *Ibid.* 1008–9.—It is found that the higher the temp. of the mineral water, the greater the d. and the smaller the pH. It is suggested that the d. of magmatic water is greater than that of tap water. T. Katsurai

The Boxhole crater and Huckitta meteorite (Central Australia). C. T. Madigan. *Trans. Roy. Soc. S. Australia* **61**, 187–90(1937); *Neues Jahrb. Mineral., Geol., Ref. I*, **1939**, 718–19; cf. *C. A.* **33**, 5777[8].—In this crater Fe-stained shale and pieces of Fe were found, the latter being an av. octahedrite similar to that found in the Henburt crater (cf. Alderman, *C. A.* **26**, 4775). C. A. Silberrad

Apatites. M. P. Fiveg and A. P. Shubin. *O. N. T. I.*

(Moscow-Leningrad) 1938, 152 pp.; *Khim. Referat. Zhur.* 2, No. 1, 25(1939).—In the deposits of volcanic origin the concn. of the phosphates seldom occurs in commercially important quantities. The amt. of apatites in the Khibin deposits is estd. at 2 billion tons contg. 430 million tons of P_2O_5. The apatite ore after treatment in the Kirovsk plant gives a concentrate contg. 39.5–39.8% of P_2O_5. The waste products are used as fertilizers, or they can be made to yield (after an addnl. flotation) a nephelite concentrate for the production of the oxides of Al, Na and P and of cement. W. R. Henn

9—METALLURGY AND METALLOGRAPHY

D. J. DEMOREST, OSCAR E. HARDER AND RICHARD RIMBACH

Occurrence and uses of the rare metals. G. Berg. *Z. prakt. Geol.* **46**, 75–7(1938); *Neues Jahrb. Mineral. Geol., Ref. II*, **1938**, 554–5.- Hess's account of the production and uses of these metals (*C. A.* **32**, 1621[7]) is amplified. Addnl. details are given for Be, Cs, Rb, Ge, Ga, Zr, Co, Li, Mo, Pt, Pd, Rh, Se, Te, U, Ra, V, W, and Ilc. C. A. Silberrad

Roasting and cyanidation of arsenopyrite concentrates. J. A. Walker. *Chem. Eng. Mining Rev.* **32**, 122–4(1940).

Notes are given on the exptl. treatment of exceptionally high-grade arsenopyrite concentrates. Four lines of treatment were followed: (*a*) roasting of concentrate in air, (*b*) removal of As under N and subsequent roasting in air, (*c*) removal of As under SO_2 and subsequent roasting in air and (*d*) destruction of the Fe_2O_3 by soln. of calcine in acid. The calcine obtained was then cyanided. Each treatment is outlined. Conclusions include: (1) Roasting arsenopyrite concentrates in air, followed by cyanidation results in high-grade residues. (2) A high temp. "finish" improves the extn. of Au from the calcine. The removal of the bulk of the As under N, followed by roasting the resulting pyrrhotite in air gives calcine from which high Au extn. is possible, but in the plant such a method would be difficult to apply. The treatment that shows the greatest promise is oxidation of the concentrate under SO_2 to produce Fe_3O_4. This product is sol. in H_2SO_3 and the soln. of the Fe oxide leaves the Au free in the siliceous residue. This residue can be recovered by filtration and subsequently cyanided. W. H. Boynton

Cyaniding gold-copper ores. R. J. Lemmon. *Chem. Eng. Mining Rev.* **32**, 103–6(1939).—A brief review of past exptl. work on the extn. of Au by cyanidation from ores contg. Cu minerals. Details are given of the use of NH_4 salts in sepg. the Cu from the Au. If the excess NH_3 is not totally combined with some of the NH_3-sol. cupric salt, the free and uncombined NH_3 will dissolve the cuprammonium cyanides and the elimination of the salts from the Au soln. effluent prior to pptn. with Zn will not be effected. NH_3 can be supplied by stirring together lime and $(NH_4)_2SO_4$ soln. with 1 lb. pure $(NH_4)_2SO_4$ requiring 0.43 lb. slaked lime to yield 0.53 lb. of NH_3. Despite the complicated equations in the cuprammonium cyanide process, the working procedure is simple. W. H. B.

Canadian nickel, its history, production and uses. K. H. J. Clarke. *Eng. J.* **22**, 505–11(1939).—A review. C. G. F.

Instrumentation in production control in a Swedish acid open-hearth furnace. Sven-Erik Brundin and Johan Paues. *Jernkontorets Ann.* **123**, 441–82(1939).—Instrumentation is not generally applied in Swedish steel production because the furnace is fired with generator gas of variable compn. and difficult to analyze automatically. In a study made on a 17-ton furnace, the production time was reduced from 9 hrs. and 9 min. to 8 hrs. and 29 min. after installation of instrumental control without affecting the fuel requirements. H. C. Duus

Vanadium oxides in iron-refining slags. A. N. Morozov. *Metallurg* **14**, No. 1, 15–27(1939).—Petrographic and thermal study of the $CaO–V_2O_3$, $CaO–V_2O_4$, $CaO–V_2O_5$, $SiO_2–V_2O_3$, $SiO_2–V_2O_4$ and $SiO_2–V_2O_5$ systems showed the existence of the compds. $2CaO.V_2O_3$, $CaO.V_2O_3$, $CaO.V_2O_5$, $2CaO.V_2O_5$ and $3CaO.V_2O_5$. CaO does not form compds. with V_2O_4. SiO_2 does not combine with V_2O_3, V_2O_4 or V_2O_5. V_2O_5 and V_2O_4 are reduced to V_2O_3 by Fe at 1600–1650°. H. W. Rathmann

Fuels and the metallurgical industry, with special reference to the iron and steel industry. Stacey G. Ward. *Proc. Staffordshire Iron Steel Institute* **54**, 44–66(1938–39); cf. *C. A.* **33**, 8545[8].—A lecture. G. T. M.

Developments in fatigue, creep, age-hardening, diffusion, microscopy, borocarbides, powders, electrodeposition and die castings. Frances H. Clark. *Mining and Met.* **21**, 18–23(1940). G. G.

Deformation and fatigue of metallic materials as detected by x-rays. Fritz Regler. *Forschungsarb. Metallkunde Rontgenmetallog.* No. **26**, 98 pp.(1939).—Deformation of metals causes both peripheral and radial broadening of x-ray diffraction spots. A no. of examples of peripheral broadening brought about by cold deformation and fatigue are shown. With moderate reductions the spots tend to merge to form lines and with increasing reduction the well-known fiber structures result. Wrought Fe members from an old bridge were examd. Some showed spots and others fibering. The significance of radial broadening is discussed. Measurements of this broadening indicated that radial line width tended to a max. characteristic of

the material, which was termed the "fracture line width." This was 6.30 mm. for pure Fe and as high as 7.80 for some alloy steels. On fractured fatigue specimens the line width rose slowly to a max. at the point of fracture. On notched specimens the width increased abruptly at the notch. The max. of the line width on materials subjected to fatigue but not fractured indicated the location at which fracture would ultimately occur. Measurements of the line width in and near welds indicated positions of stress concn. Several practical applications of radial broadening of x-ray lines are given. One is in reference to axles from an elec. locomotive in which one axle had failed. Broadening of the lines near a change in section indicated a point of dangerous stress concn. and that other axles would fail by fatigue. Others did, and the design was changed. Detailed directions for x-ray study of fatigue damage are given. J. L. Gregg

Radiographic development in the casting industries. Charles W. Briggs. *Metals & Alloys* **11**, 1–5(1940).—A historical review followed by a discussion of the importance of radiography to the designer and in mfg., and of its special application in the inspection of Al and steel castings. I. Hartmann

Flame hardening in the commercial heat-treating plant. W. G. Hamilton. *Heat Treating Forging* **26**, 23–5(1940).—The Gleason flame hardening machine is described and its application to the heat-treatment of large gears, cast-iron plungers, and internal cams is discussed. I. H.

Forgings for steam-turbine rotors. Hans Dahlstrand and H. J. Stein. *Heat Treating Forging* **26**, 9–15(1940).—An outline of present practice of making suitable forgings for steam-turbine spindles with special emphasis on the prepn. of ingots, forging, heat treatment, machining and special alloys developed recently for high-temp. operation. The latter include C-Mo-V, Ni-Mo, Cr-Ni-Mo alloys; their compn. and phys. properties are described. I. Hartmann

Influence of the degree of ammonia dissociation upon the nitrided surfaces. Yu. M. Lakhtin. *Aviapromyshlennost* **1939**, No. 10, 35–43.—Steel rods contg. C 0.33, Si 0.37, Mn 0.45, P 0.022, Cr 1.41, Mo 0.42 and Al 1.11% were nitrided for 24 hrs. at 520° under degrees of NH_3 varying from 5 to 90%. By increasing the degree of dissocn. up to 65–70% the hardness of the nitrided layer and the depth of N diffusion were not adversely affected. A higher degree of dissocn. produces large decreases in hardness of the nitrided layers and also in the depth of N diffusion. In the interval up to 45–50% dissocn. the microstructure of the nitrided layer did not change and at higher dissocns. the structure assumes a less differentiating character. No increase in brittleness was observed with increasing degree of NH_3 dissocn. B. Z. Kamich

The disposal of waste acids. W. W. Hodge. *Wire & Wire Products* **15**, 32–42(1940); cf. *C. A.* **34**, 6341.—A review of methods for the disposal and utilization of waste pickle liquor, including 19 references. George Ayers

Review of iron and steel literature for 1939. E. H. McClelland. *Heat Treating Forging* **26**, 28–33(1940).—The twenty-third annual review of iron and steel literature published separately in books and pamphlets. I. H.

A preliminary study of gases in cast iron. Wm. Y. Buchanan. *Foundry Trade J.* **61**, 423–4, 443–6(1939).—Existing knowledge is summarized and several brief abstracts are included. Exptl. work on dissolved gases, cast iron, rust treatment, mill-scale addn., etc., is described. Conclusions: (1) Sparking is said to indicate oxidation, i. e., gassy metal. This appears to be incorrect, as sparking occurs at high temps. and low Si range, whereas the gas vol. may be much greater in high-Si iron. (2) Fluidity and life must play an important part in the ultimate performance of the quantity of gas present as, for example, good castings can be had from high-P, or high-C, high-Si, medium-P iron even with excessive gas content, but the element of risk will always be present. (3) Moisture is the cause of most gas formation in cast iron. (4) Gas escaping rapidly through metal may to a certain extent delay freezing locally. (5) In high-duty irons the presence of gas is more severe than in low-grade irons, owing to the tendency to low fluidity and life in these irons. (6) Apart from the many causes of gas holes, dissolved gas must always be an addnl. contributing factor. (7) The permissible vol. of gas in molten cast iron can be established by some research. I. Hartmann

Ten years' progress in cast iron. J. G. Pearce. *Metallurgia* **21**, 41–2(1939). J. L. Gregg

Types of high-duty cast irons. A. J. Nicol Smith. *Foundry Trade J.* **62**, 51–2, 53(1940).—Two types of cast irons are considered: Those which have high strength properties, and "special irons," which are high-duty in respect to some other special property, such as corrosion resistance. Austenitic irons are the most important class of special irons; they have very good corrosion and heat resistance. Martensitic irons are wear resistant. High-Si irons have considerable heat resistance and good acid resistance, but are brittle and difficult to manuf. and machine. High-Cr irons have good corrosion and heat resistance; their mech. properties vary with the total C content. High-Al irons can be made with good mech. properties; they are very heat resistant, especially in oxidizing or sulfurous atms. I. Hartmann

Effect of sintering time, sintering temperature and pressure of compression on the mechanical properties of sintered iron. W. Eilender and R. Schwalbe. *Arch. Eisenhüttenw.* **13**, 267–72(1939).—A fundamental phenomenon of the sintering process is the occurrence of a sudden grain growth, which takes place for all grain sizes between 850° and 900°. This sudden growth is attributed to stresses within the crystal lattice, which are characteristic for the cold-deformed state. With increasing sintering temp. a rapid increase of strength is at first observed followed by a distinct drop in strength which however stops at higher temps. Increasing pressure increases tensile strength, elastic limit, elongation and density considerably. Sintering time increases tensile strength up to about 2 hrs.; after this the tensile strength remains const. Elongation increases steadily, and elastic limit shows a min. at about 30 min., but in general changes little with time. The sudden grain growth is not affected by the pressure. Sintering temp. has a very irregular effect on tensile strength, elastic limit, elongation and reduction of area, although the character of all these curves is fundamentally the same. From 500°, tensile strength increases rapidly to a max. at 800°, decreases to a min. at 1000° and increases again up to 1200°. M. Hartenheim

Progress in steel metallurgy during the last ten years. W. H. Hatfield. *Metallurgia* **21**, 33–5(1939).—A review in which new materials and new methods are briefly mentioned. J. L. Gregg

High-temperature steels. N. A. Minkevich and A. M. Borzdyka. *Metallurg* **14**, No. 1, 61–78(1939).—Steels contg. C 0.4, Cr 14.7, Mn 12.2, W 2.2 and Si 1.8% and C 0.4, Cr 14.1, Mn 13.6, Mo 3.1 and Si 1.65% were found satisfactory with respect to corrosion resistance and mech. properties for service at 850–950°. H. W. R.

Investigation of decarburization and oxidation of high-speed steel. N. M. Lapotyshkin. *Ural. Met.* (*Ural. Ind. Inst. im. S. M. Kirova*) **1938**, No. 11, 22–7; *Khim. Referat. Zhur.* **2**, No. 4, 96(1939).—High-speed steel (grade "R") contg. C 0.67, Mn 0.31, Si 0.36, Cr 4.3, W 18.22, and V 0.42% was used for the expts. Samples of this steel were heated to 1280°, held at this temp. and tempered. On heating the sample in the interval 700–1100° and holding it for 0.5–12 hrs., an increase of the temp. increases the degree of decarburization. The decarburized steel is rapidly transformed to normal steel at 950–1000°. At higher temps. a gradual transformation takes place. The greater the temp. the faster the ferrite zone appears. Heating in a neutral atm. effects min. decarburization; in an oxidizing atm. decarburization is max. With increase of temp. and time of holding of the steel, the loss of wt. increases, but the oxidation velocity decreases with an increase of the duration of holding. Holding at high temp. favors grain growth and formation of tube-type crystals in the decarburized layer. The results of the expts. are presented in the form of graphs,

diagrams and tables. Photographs of the microstructures are given. W. R. Henn

The critical cooling rate of steel. M. M. Zamyatnin. *Metallurg* **13**, No. 12, 29–38(1938).—Assuming Newton's law of cooling by conduction and the Stefan-Boltzmann radiation law, it is shown that the critical quenching rate of eutectoid steel is 200° per sec. at 900° for a specimen cooled solely by conduction and 600° per sec. for a specimen cooled solely by radiation. This difference is caused by the different form of the 2 cooling curves. Actual exptl. critical cooling rates are between the above values. H. W. Rathmann

The fatigue endurance of killed, capped and rimmed steels. J. F. McDowell. *Metals & Alloys* **11**, 27–32 (1940).—Killed, capped and rimmed steels of approx. similar chem. compn. and nearly identical phys. properties have been found to vary quite definitely in their ability to withstand stress reversals. The fatigue ratios (ratio of fatigue endurance to tensile strength) detd. are, resp., 0.50 for killed steels, 0.42 for capped steels and 0.37 for rimmed steels. In the calcn. of the limiting stress, cognizance of this fact must be taken when either of the latter two steels is involved. Skin decarburization is the cause of the low fatigue endurance of the rimmed and capped steels. Segregation of elements other than C away from the skin plays a minor role in the effect upon fatigue properties. I. Hartmann

The quality of steel in relation to hot-working properties. H. A. Dickie. *Proc. Staffordshire Iron Steel Inst.* **54**, 33–40(1938–39).—The steel compn. and the process of making inpurities and addns., affect the characteristics of hot-working of steel. Red shortness due to Cu may be minimized by addn. to the steel of Ni to the extent of about half the Cu content. G. T. Motok

Precipitation hardening of mild, unalloyed steels. H. Wilhelm and J. Reschka. *Arch. Eisenhuttenw.* **13**, 273–5 (1939).—Plain steels with 0.04–0.2% C were quenched in water from 650° and then stored at 18°; hardness and tensile strength were regularly tested over about 5 years. The hardness decreased after 100 days steadily up to 1500 days more or less according to C content, in av. 30–38%. This process is considered to be a kind of tempering effect, contrary to the effect of pptn. hardening, and seems to be dependent on temp. of storing. M. Hartenheim

Consideration on cast steels of high mechanical resistance. Georges Delbart. *Bull. assoc. tech. fonderie* **13**, 338–46(1939).—The primary structure, homogenization and final treatment of cast steel affect the mech. resistance. 9 references. G. T. Motok

Mechanical properties of rolled carbon steel at low temperatures. I. V. Kudryavtsev. *Vestnik Metallo-prom.* **19**, No. 3, 6–15(1939).—Various beam shapes made from low-C, open-hearth, Bessemer and Thomas steel were tested at temps. down to −70°. In lowering the temp. from 20° to −70° there was an increase in all cases of the tensile strength, yield point and relative elongation, with the yield point increasing much more rapidly than the tensile strength. The impact toughness was decreased. The results were not substantially affected by normalizing. For all steels the effect of riveting and subsequent aging was to reduce the impact toughness, open-hearth metal having the least decrease. For this steel the impact toughness was practically the same for the interval 20° to 0° both before and after aging, while for lower temps. the differences were not great. Bessemer steel had the largest drop in impact toughness, especially from 20° to 0° and the same was true for Thomas steel, but to a lesser extent. The hardness increased with decreasing temp. It is suggested that the serviceability of metals be judged from their impact toughness. B. Z. Kamich

Manganese in carbon steels. Bernard Thomas. *Metallurgia* **21**, 73–5(1940).—Two steels contg. 0.53 or 0.54% C, one with 0.67% Mn and the other with 0.81% Mn were tested in the form of strips 0.12 in. thick and thinner. They were tested by supporting each end and bending with a load applied at the middle of the specimen. Deflection at load and permanent set were detd. The steels were tested as-rolled, annealed and as quenched and tempered. Results were considered to prove that the 0.14% more Mn in the one steel greatly improved strength or "resilience." J. L. Gregg

The effect of special elements on the properties of chromium-silicon-vanadium high-speed steel. N. T. Gudtsov, A. N. Bekova, S. A. Kazeev and A. V. Polyakov. *Metallurg* **14**, No. 1, 51–61(1939).—Addns. of Mo (0.35–3.18%), Co (0.66–6.3%), Ti (0.12–0.38%) and a Cb-Ta mixt. (0.1–2.0%) were made to steel contg. C 1.0–1.2, Cr 10–13, Si 0.9–1.6 and V 2.0–2.5%. Mo and Ti improved the cutting properties; Co and the Cb-Ta mixt. showed no effect. Steel contg. 3.18% Mo was equal or slightly superior to a W 18, Cr 4 and V 1% steel. H. W. Rathmann

Properties and machinability of a leaded steel. T. J. Dolan and B. R. Price. *Metals & Alloys* **11**, 20–7(1940); cf. Robbins *C. A.* **33**, 9248⁵.—The usual static, impact and fatigue properties and the machinability of an ordinary S. A. E. 1045 steel, to which 0.20% Pb had been added, were studied. The steel was tested in 3 conditions, namely (*a*) cold drawn, (*b*) normalized and (*c*) quenched-and-tempered. In general the static phys. properties are very similar to those of an ordinary C (nonleaded) steel, and indicate that the addn. of a small amt. of Pb did not impair these properties in any way. The Charpy impact strengths of the cold-drawn samples are considerably lower than for the normalized and quenched-and-tempered specimens; all results are about in the range generally obtained for nonleaded C steel under similar testing conditions. The same is approx. true of the fatigue properties of the steels; the quenched-and-tempered leaded steel is highly "notch-sensitive." The relative machining qualities of these steels and of various other C steels and cast irons were evaluated by detg. the h. p. required to drill small holes in each metal in a special dynamometer drill press. The power required for the leaded steel specimens was lower than for any of the materials tested except for cast iron and for screw stock steel S. A. E. X1112. Economically the leaded steel is more expensive in initial cost, but the machinability tests indicate that in many applications a saving can probably be made in processing cost and in the general speeding up of production. 5 references. I. Hartmann

Hardenability of molybdenum S. A. E. steels. Robert M. Parke and Alvin J. Herzig. *Metals & Alloys* **11**, 6–13 (1940).—The hardenabilities of eight Mo-bearing S. A. E. steels, one Mn-Si-Mo steel, and one C steel were studied by obtaining their temp. *vs.* isothermal-reaction-time curves (S curves). The shapes of the alloy-steel curves are significantly different from those for C steels. Each of the 9 alloy steels has a more or less prominent reversal in its S curve below about 650°. The effect of the alloys in reducing the crit. quenching rate is clearly indicated by the shifting of the nose toward greater time. The effect of the alloys Ni, Cr and Mo on the lower portion of the curve is relatively small and greatly overshadowed by the effect of C. The effect of increasing C in expanding the region of austenite stability below 250° gives a more definite understanding of the varied response of low-, medium- and high-C steels to hardening. The results indicate the possibility of selecting steels with an alloy content sufficient to reduce the crit. cooling rate to fit the section size (or heat-treating practice) and with a C content that will enforce transformation to an acicular product of the desired hardness when treated by conventional liquid or air quenches. The S curve is a useful supplement to the equil. diagram for it defines a system that is not in equil., a condition prevailing in ferrous metallurgy far more frequently than the usually hypothetical equil. condition. I. Hartmann

Titanium in forging steel. Geo. F. Comstock. *Heat Treating Forging* **26**, 26–7(1940).—Residual-Ti contents of about 0.1% or more prevent the formation of coarse dendrites in small ingots of 0.35 to 0.40% C steel poured at about 1595 to 1620°, while similar amts. of Al or Zr were not effective. With over about 0.2% residual Ti content and addn. of 0.05 to 0.15% Al the grain-coarsening

temp. of forged 0.35 to 0.40% C steel was found to be above 1065°. I. Hartmann

Filtration of metallic systems and determination of the nature of phases in alloys. M. P. Slavinskiĭ and N. L. Kleĭman. *Metallurg* **13**, No. 12, 68–80(1938).—An alloy contg. Sn 83, Sb 11.5 and Cu 5.5% was fused, cooled at 0.3–0.4° per min. and filtered in a CO_2 atm. with a quartz sand filter at 280° and 240°. CuSn was sepd. at 280° and Sn_3Sb at 240°. The filtrate contained Sb 7.38, Cu 1.12% and balance Sn. An alloy contg. Sn 11.37, Sb 11.60, Cu 2.08, Cd 1.45, As 1.34% and balance Pb yielded SnSb, Sn_3Sb and 3 phases identified as eutectics. A Pb alloy contg. Ca 0.8 and Na 0.8% yielded Pb_3Ca ppt. and a Ca-free filtrate. H. W. Rathmann

β'-β Transformation in lithium-lead alloys. Thomas C. Wilson. *J. Chem. Phys.* **8**, 13–19(1940).—Measurements made by Grube and Klaiber (*C. A.* **29**, 987[4]) on Li-Pb alloys indicate that a peculiar transformation occurs in the β-phase of these alloys. The behavior of this transformation was investigated up to pressures of 10,000 kg./sq. cm. by measurements of the elec. resistance. These results, with those from rough thermal-expansion measurements, indicate that the transition occurs gradually on heating from a phase of abnormally high energy and entropy content to a phase of more normal character. X-ray analyses show that the transition is accompanied by movements of the Li atoms in the lattice to more orderly positions. G. M. Petty

Casting of alloy 6852. A. V. Provorov. *Aviapromyshlennost* **1939**, No. 10, 20–4.—The alloy 6852 contains 9.5–11.5% Al, 4.0–6.0% Fe, 4–6% Ni, 0.1% Mg and the rest Cu. The alloy was cast by pouring into sand molds and by centrifuging. The latter method gave a greater compactness and less gas inclusions and porosity than the former method. The castings from both methods had small-grained structures. The recommended heat-treatment: quenching in water at 900–915°, holding for 15 min., and tempering at 650–700° for 1.5–2 hrs. B. Z. Kamich

Light alloys of aluminum. A. von Zeerleder. *Metallurgia* **21**, 47–53(1939).—Although about 850 Al alloys are listed in Gmelins handbook, the no. really useful may be reduced to about 24. Of these 24, half are casting alloys and half are wrought alloys. Each of these groups may be divided into hardenable and non-hardenable alloys. Some of the more important alloys are discussed and properties of cast and wrought alloys are listed. Although Al is expensive, Al castings are frequently cheaper than Fe castings designed to do the same job. J. L. Gregg

Copper and copper alloys: a survey of technical progress during 1939. H. J. Miller. *Metallurgia* **21**, 43–6(1939).—A review with 56 references. J. L. Gregg

Alloy cast irons. P. A. Russell. *Proc. Staffordshire Iron Steel Inst.* **54**, 72–5(1938–39).—Principally alloying elements added to cast irons are Ni, Cr, Si, Mn, Cu and Mo. The addn. of elements causes much greater solidification shrinkage than in nonalloyed cast irons. G. T. Motok

The system iron–cobalt–antimony. W. Geller. *Arch. Eisenhüttenw.* **13**, 263–6(1939).—After a brief review of the binary systems Fe–Co, Fe–Sb and Co–Sb, the results of the thermal, dilatometric and structural examn. of the system Fe–Co–Sb are described in detail. This ternary system has a simple form; no new phases besides the phases of the 3 binary systems occur. The ε-phase of FeSb forms with CoSb a continuous series of solid solns.; both phases are orthohexagonal, of the form of Ni arsenide. Phases $FeSb_2$ and $CoSb_2$ both of which form peritectics in the binary marginal systems, also form a continuous series of solid solns. An alloy of 5% Sb, 76% Co and 19% Fe was quenched from 1000° and tempered at 850°; it lies outside the γ-α-transformation. Other alloys of this system showed that no pptn. hardening takes place; hence these alloys have no practical importance. Five references. M. Hartenheim

Forging and stamping of airplane propeller blades from magnesium alloys of high strength. S. M. Voronov and L. Ya. Shpolyanskiĭ. *Aviapromyshlennost* **1939**, No. 2, 24–33.—Mg alloys contg. 4.5–5% Al, 0.5–0.6% Zn and 0.3–0.5% Mn are forged much less easily than alloys of the type Dow F. The max. extent of deformation during forging should not be over 20–25% to prevent destruction of the material. The alloy has a more narrow temp. interval of forging than the alloys contg. 4–4.5% Al of the Dow F type. The recommended temp. interval is 330–350°. The stamped blades of the Al-Zn-Mn alloy should be heat-treated by either of the following methods: (1) heating at 350–400° for 6–12 hrs. followed by air cooling or (2) heating at 420° for 2 hrs. followed by 12-hr. aging at 200°. B. Z. Kamich

The heat treatment of "K" monel and "Z" nickel. Staff Development and Research Division, International Nickel Company, Inc. *Heat Treating Forging* **25**, 593–7(1939); **26**, 16–20, 25(1940).—"K" monel is an alloy contg. approx. Ni 66, Cu 29 and Al 2.75%. "Z" nickel is an alloy contg. approx. 98% Ni. These alloys are corrosion resisting and may be hardened by aging at moderate temps. The mech. properties obtained from various forms and tempers are indicated and the cycles of heat treatment and best heat-treating conditions are described in detail. I. Hartmann

Nickel-columbium alloys. S. A. Pogodin and A. N. Zelikman. *Metallurg* **14**, No. 1, 8–14(1939).—Ni-Cb alloys contg. up to 69% Cb and only traces of Al were prepd. by aluminothermic reduction of Cb_2O_5 and NiO using 95% of the stoichiometrically required Al. Cb recovery was 60–70%. Hardness tests, elec. cond. measurements and micrographic study indicated a max. soly. of 11–12% Cb in Ni solid soln. at 900°. At higher concns. Ni_3Cb was formed. H. W. Rathmann

Study on the corrosion of iron by electron diffraction. Sizuo Miyake. *Sci. Papers Inst. Phys. Chem. Research* (Tokyo) **36**, 363–70(1939)(in English).—A study of the electron-diffraction patterns obtained from Armco iron immersed in NaCl solns. for varying lengths of time shows that the uppermost surface is γ $Fe_2O_3.H_2O$. When this is removed, there is revealed, depending on the time of immersion, an adherent layer of either γ Fe_2O_3 or a new substance, called the "two-ring substance" from its diffraction pattern. This new substance is shown probably to be intermediate in compn. between the other 2 oxides. E. O. Wiig

Effect of sulfur and sulfur compounds in naphtha upon certain corrosion tests. Sensitivity of the doctor test. L. M. Henderson, M. S. Agruss and Geo. W. Ayers, Jr. *Ind. Eng. Chem., Anal. Ed.* **12**, 1–3(1940).—The effects of a no. of mercaptans, sulfides, disulfides, of free S, dibutyl sulfone, and thiophene, dissolved in Stoddard solvent, varnish makers' and painters' naphtha, and rubber solvent upon the distn.-corrosion test, the Cu-strip corrosion test at 50°, and the doctor test were studied. There are two detg. factors pertaining to distn.-corrosion test on S compds. in naphtha soln.: (1) the b. p. of the S compd. with reference to the boiling range and end point of the solvent and (2) the stability of the S compd. at moderately high temps. In many instances the quantity of the S compd. also affects the corrosion test. In general a more corroded strip is obtained in this test with higher-boiling naphthas than with lower-boiling ones. A 0.05% soln. of free S in Michigan Stoddard solvent was found to be strongly corrosive to Cu in the Cu-strip test; a concn. of 0.003 to 0.004% free S just affects a Cu strip. The sensitivity of the doctor test for 7 mercaptans was detd. to be practically the same in each of three naphthas. 17 references. I. Hartmann

Electrode coatings for welding aviation steels. E. P. Rogozhkin. *Tekhnika Vozdushnogo Flota* **1939**, No. 3, 31–50.—The effects of various electrode coatings upon the arc stability in welding of aviation steels were studied. From the point of view of arc stability and appearance of the weld the following two coatings are suggested: (1) $BaCO_3$ 33.3, Cr_2O_3 16.6, MnO_2 16.6, and chalk 33.3% in case of direct polarity, and (2) $K_2Cr_2O_7$ 7.7, kaolin 30.8, pyrolusite 23.1, TiO_2 7.7, $NiCO_3$ 15.4, and chalk 15.4% in case of reversible polarity. The resulting welds were dense, clean, and had no gas or slag inclusions. B. Z. K.

Flotation apparatus for separation of ore-pulp constituents. Alva H. Garrett (50% to Charles O. Parker). U. S. 2,179,622, Nov. 14. Various structural, mech. and operative details.

Froth flotation of ores with use of substituted biguanides as flotation reagents. David W. Jayne, Jr. and Arvid E. Anderson (to American Cyanamid Co.). U. S. 2,180,926, Nov. 21. In the flotation treatment of ores such as those of Cu, Pb and Au, use is made of ethylene-*o*-tolylbiguanide hydrochloride or other substituted biguanide of the general formula $RR_1NC(:NH)NHC(:NH)NH_2$ in which R and R_1 represent H or alkyl or aryl radicals, or of an acid salt or aldehyde condensation product of such a substituted biguanide.

Apparatus for concentrating ores by sedimentation. Charles E. Wood. U. S. 2,180,574, Nov. 21. Various structural and operative details.

Working up ores and other metallurgical raw materials. Aurél Bognár. Hung. 122,479, Dec. 15, 1939. Sulfide-contg. substances, or mixts. of free S with nonsulfide materials, are treated at temps. above 150° and pressures above 60 atm. with steam and oxygen or O-contg. gases. The nascent SO_3 converts the metals to sulfates. Nitric acid or nitrates or nitrous gases can be used as catalysts.

Rotary bowl and vibrating apparatus for classifying materials such as those of gold-ore pulps. Jes Asmussen (to A. O. Smith Corp.). U. S. 2,179,807, Nov. 14. Various structural and operative details.

Apparatus for separating materials, such as sand and titanium, by flotation. Russell S. Ellis. U. S. 2,180,278, Nov. 14. Various structural, mech. and operative details.

Treating vanadium ores also containing uranium and radium. John S. Potter (to S. W. Shattuck Chemical Co.). U. S. 2,180,692, Nov. 21. A process of treating a vanadiferous ore contg. U and Ra values involves prepg. a relatively thick mixt. of the ore, in comminuted condition but not comprising a large proportion of fines, with strong H_2SO_4, allowing the ensuing reaction to take place substantially by the heat of reaction alone, breaking up the resultant reaction mass and leaching with water to obtain a leach liquor contg. dissolved V and U values, together with radium-bearing slimes suspended therein sepg. from the residual sands the leach liquor with the suspended slimes, and then sepg. the slimes from the leach liquor as a radium-bearing concentrate.

Slags containing vanadium. Soc. industrielle & commerciale des aciers, Fr. 841,006, May 9, 1939. Slags contg. V are made from pig contg. V and Mn by eliminating the Mn and refining the remainder. Mn is eliminated by adding to the molten mass S or substances contg. S, such as pyrites. MnS is formed and is removed.

Hearth furnace adapted for heating billets, etc. George R. McDermott (to Surface Combustion Corp.). U. S. 2,180,089, Nov. 14. Various structural and operative details.

Gas-fired furnace suitable for melting or heating metals. Stephen Stanworth and James Stanworth. U. S. 2,180,774, Nov. 21. Various structural and operative details.

Checkerwork construction suitable for use with blast

furnaces. Arthur G. McKee. U. S. 2,179,666, Nov. 14. Various structural features.

Composition for foundry molds, etc. Norman J. Dunbeck (to Eastern Clay Products, Inc.). U. S. 2,180,897, Nov. 21. Sand is used with a reversible binder of nonswelling, colloidal montmorillonite.

Casting malleable iron. Albert W. Morris (to Morris Engineering Corp.). U. S. 2,179,513, Nov. 14. App. is described, and a method involving pouring the metal into a mold such as one of Cu contg. about 1% Fe.

Aluminum. Henri L. Gentil. Fr. 841,109, May 10, 1939. Compds. contg. Al, such as bauxite, clay, volcanic ash, etc., are treated with a reducing agent at 1800° and under a vacuum of 2 mm. pressure. Example is given of heating a mixt. of bauxite and Fe pyrite in an elec. furnace at 1800° under a pressure of 2 mm. Al is liberated, volatilized and condensed. SO_2 is a valuable by-product in the reaction.

Lithium-copper. Harold J. Ness (to Nesaloy Products, Inc.). U. S. 2,181,092, Nov. 21. Molten Cu in a furnace (details of which are described) is heated in the presence of Li vapor.

Separation of nickel from copper. Guenther Hamprecht and Gustav Pauckner (to I. G. Farbenind. A.-G.). U. S. 2,180,520, Nov. 21. A Cu-Ni matte is treated with Cu chloride soln. with the formation of Ni chloride and CuCl and part of the soln. of the latter is treated with Cl to form $CuCl_2$ and the soln. thus obtained is employed for the treatment of further amts. of the Ni-Cu matte, the other part of the soln. from the matte treatment being treated for pptn. of the Cu by the action of Ni-Cu matte.

Purifying lead and tin. Louis S. Deitz, Jr. (to Nassau Smelting & Refining Co.). U. S. 2,180,139, Nov. 14. A process of treating a commercially pure alloy consisting of upward of 80% of Pb or Sn to remove residual abrasive impurities which tend to cause surface irregularities in finished products made therefrom, while maintaining the composition of the alloy substantially unaltered, the alloy being one which would normally be used at temps. well above its freezing point without further purification for the manuf. of slush castings, extruded shapes, bearings, etc., comprises heating such an alloy to a temp. at which all of its constituents are molten and which approximates that at which it will be employed in the manuf. of the products, cooling the alloy to a temp. substantially lower than that at which it is initially heated and lower than that at which it will be employed in the manuf. of the products, removing the small quantity of insol. material produced, and reheating the alloy to a temp. suitable for its intended use.

Heat-treatments such as annealing, hardening or normalizing steels. Arthur H. Vaughan (to Electric Furnace Co.). U. S. 2,180,376, Nov. 21. App. is described, and a method involving treating a hydrocarbon-contg. gas with air in predetd. proportions to provide reaction products contg. CO_2, water vapor and undissocd. hydrocarbons in excess of the amt. of CO_2, removing at least a part of the water, reheating the remaining reaction products to about 980–1090° to react the CO_2 and undissociated hydrocarbons and provide a nondecarburizing gas, and utilizing the noncarburizing gas as an enveloping and protecting atm. in a heat-treating furnace.

Apparatus for heat-treating metal articles as in hardening crankshaft surfaces, etc. Francis S. Denneen, Wm. C. Dunn and Courtney N. Mitchell (to Ohio Crankshaft Co.). U. S. 2,180,038, Nov. 14. Various structural, mech. and operative details.

Inhibiting oxidation of metals such as steel during heating. Harold J. Ness (to Nesaloy Products, Inc.). U. S. 2,181,093, Nov. 21. App. is described, and a method of heating metals in an atm. contg. Li or a Li compd. and CO.

Light-metal pistons. The Birmingham Aluminium Casting (1903) Co. Ltd. and Frank G. Woollard. Brit. 507,084, June 9, 1909. A light-metal piston, e. g., of Al alloy, has a hard coating of an oxide of the metal or 1 of the constituent metals of the piston on its head part and a coating of a suitable soft bearing metal, e. g., Sn, on its skirt. The oxide coating may be dyed; it may be produced by anodic oxidation of the head immersed in a suitable bath, the skirt being protected during the oxidation process by means of a rubber or like impervious material.

Agglomerated materials such as compositions for electrical contacts. Paul Schwarzkopf. U. S. 2,179,960, Nov. 14. There are used together at least one metal selected from a first group consisting of W, Mo and Ta, and at least one metal selected from a second group consisting of Ag, Ni, Co, Fe, Cu, Al, Au, Cr, Sn, Zn and Pt, the metal of the first group present in individual dense particles coarser than those of the original metal powder obtained from its compds. or ores, and obtained in such coarser state by heat-treatment at temps. at least as high as sintering temp. and subsequent powdering, the metal of the second group forming substantially a solidified melt agglomerating the individual coarse particles and present in amts. of about 3–90% of the material or bodies.

Electric contacts. Franz R. Hensel (to P. R. Mallory & Co.). U. S. 2,180,956, Nov. 21. Contacts which are resistant to oxidation are formed of 50–99% of one or more of the nitrides of Ti, Zr, Hf, V, Cb and Ta, together with 1–50% of Ag, Cu or Au or their alloys.

Pig iron. Herman A. Brassert and Tom P. Colclough (to H. A. Brassert & Co.). Can. 386,453, Jan. 23, 1940. In a coke-fired blast furnace the m. p. of the slag is lowered by decreasing the ratio of lime to SiO_2 to about unity. This causes liquefaction of the slag-forming materials high enough in the furnace to permit superheating of the descending liquid slag by the ascending hot gases. This superheating increases absorption of impurities from the iron by the slag during the descent to the hearth. Excess S is removed by further treatment, e. g., by adding a Mn alloy and maintaining an oxidizing atm. in contact with the Mn slag surface.

Lithium treatment of furnace atmospheres in heating steel, etc. Harold J. Ness (to Nesaloy Products, Inc.). U. S. 2,181,094, Nov. 21. App. is described, and a method of creating an atm. contg. metallic Li in a furnace or the like which involves mixing a compd. of Li such as Li_2CO_3 with powd. C, introducing the mixt. with O or an O-contg. gas into a furnace and maintaining a sufficiently high temp. in the furnace to effect a reduction of the Li compd. to metallic Li. U. S. 2,181,095 relates to preventing oxidation of metals by a heating torch such as a gas torch which involves introducing Li or a Li compd. into the flame of the torch. U. S. 2,181,096 relates to making lithiated ferrous metals by heating metals such as steel to their m. p. in an atm. which exhibits a strong Li spectrum. U. S. 2,181,097 relates to conditioning a furnace in which a Li-contg. atm. is to be produced, which involves applying to the lining of the furnace a Li compd. such as LiCl or Li_2CO_3 in a liquid dissolving or suspending medium such as water.

Steel for the production of objects subjected to great wear. Kohle- und Eisenforschung G. m. b. H. Fr. 841,054, May 10, 1939. A steel highly resistant to wear, obtained by basic fusion, particularly, Thomas steel, comprises C 0.10–0.25, Mn 0.9–1.6, P 0.08–0.25, Si 0.6–2.5% and the remainder Fe and the usual impurities, is particularly suitable for the manuf. of rails, tires, piles and other objects subjected to great wear. The increase in the content of Si has greatly increased the toughness and the resistance to wear. Cu 0.25–0.5 and Cr 0.5% can be added to increase the corrosion resistance.

Increasing the resistance of steel to hydrogen under pressure. Kohle- und Eisenforschung G. m. b. H. Fr. 841,055, May 10, 1939. The resistance of steel contg. separately or together, Cr, Mo, V and other elements capable of forming carbides, to an attack by H under pressure is higher the lower the Mn content. Usually steel with a Mn content below 0.25% is fairly resistant.

Forming finned tubing of metals such as copper, brass or an aluminum alloy. Albert J. Townsend and Frank J. Bascombe. U. S. 2,179,530, Nov. 14. In flattening finned tubing, spaces between fin elements are filled with a deformable material such as Pb of sufficient hardness to

support the finning during deformation, followed by flattening and removal of the filling material. App. is described.

Dentures of cobalt alloys. Charles H. Prange (to Austenal Laboratories, Inc.). U. S. 2,180,549, Nov. 21. Dentures are formed of alloys having only slight shrinkage on solidifying and which contain Co together with Cr 10–40 and Mo about 5–20%.

Ferrous alloys suitable for cylinder liners, pistons, piston rings, etc. Walter E. Jominy (to General Motors Corp.). U. S. 2,179,695, Nov. 14. Alloys which have good wear resistance contain Fe together with C 2.25–4.0, Si 1.5–3.5, Ti 0.05–0.60, P 0.6–1.25 and Mn 0.3–1.0%.

Hard molybdenum alloy suitable for facing cutting tools, etc. Allen E. Wisler and Henry B. Woods (to Hughes Tool Co.). U. S. 2,179,836, Nov. 14. An alloy is used which may be formed of Mo 87, B 4, Cr 6 and C 3% (the proportions being variable).

Tin alloys suitable for casting pliable ornamental articles. Charles H. Bell, Louis S. Deitz, Jr., and Abraham I. Stein (to Nassau Smelting and Refining Co.). U. S. 2,180,137, Nov. 14. Sn is used with Cu 0.90–1.05 and Cd 0.01–0.1%.

Zinc alloys. Wm. H. Finkeldey (to Edes Mfg. Co.). U. S. 2,180,291, Nov. 14. Alloys which are suitable for casting, rolling, etc., contain Zn having not more than 0.01% impurities together with Al about 0.25–1.75 and Mg about 0.003–0.035%. U. S. 2,180,292 relates to alloys of Zn (of like high purity) with Al about 0.1–1.75, Mg 0.001–0.035 and Mn 0.002–0.25%. U. S. 2,180,293 relates to engraving plates formed from like high purity Zn alloyed with Al 0.25–1.75 and at least one of the metals Mg 0.003–0.035, Mn 0.002–0.25, or Cu 0.01–0.2%.

Metallic printing plates or cylinders. Josef Horn (50% to Erich Weber). U. S. 2,181,111, Nov. 21. A method of producing metallic printing plates or cylinders for relief printing comprises superimposing upon a pliant ground plate of Al or Mg or an alloy thereof, at least one intermediate layer of Zn, Cd or an alloy thereof, superimposing on the intermediate layer or layers at least one layer of heavy wear-resistant metal characterized by an ability to carry printing ink and consisting of Cu, brass, tombac, Cr, Ni, alpaca, Ag, steel or an alloy thereof, and removing all of the metal layers superimposed on the ground plate at the nonprinting areas to such an extent that the top surface of the ground plate is exposed.

Chromium-coating iron and steel articles. Karl Daeves, Gottfried Becker and Fritz Steinberg. Fr. 840,975, May 8, 1939. Fe and steel articles are treated with gaseous $CrCl_2$ through ceramic carriers, such as porcelain. (1) The articles are placed in a reaction furnace, in presence of the ceramic carriers, and a stream of gaseous $CrCl_2$ is passed through the furnace heated to 1000°; (2) the articles surrounded by pieces of porcelain or other ceramic substances previously enriched in $CrCl_2$, are heated to 950–1000°; or (3) the articles are heated, in presence of the carriers and of substances which at high temp. emit gaseous $CrCl_2$.

Preventing corrosion of ferrous metals by liquids such as nitrogen compounds. Robert W. Moncrieff and Edward B. Thomas (to Celanese Corp. of America). U. S. 2,180,427, Nov. 21. A liquid contg. a nitrogenous base, such as ethylene diamine, which normally has a corrosive action on Fe is used with an alk. earth metal compd. such as $Ca(OAc)_2$, which is convertible by aq. CO_2 into a water-insol. carbonate, in sufficient amount to inhibit materially such corrosive action.

Welding electrode. John T. Marvin (to General Motors Corp.). U. S. 2,180,813, Nov. 21. A flux-carrying electrode is made by molding finely divided metal powder into the desired shape, sintering to form a highly porous product and impregnating the product with fluxing ingredients which solidify and are held within the pores of the electrode. Various examples are given.

Electrode for use in spot welding. Geo. Goldstein (to General Motors Corp.). U. S. 2,179,693, Nov. 14. A coating of Hg is used between a body of material such as Cu and a tip which may be formed of Cu or "elkonite" and serves to permit movement of the tip.

Electrical contacts such as those of spot-welding apparatus. James P. Burke. U. S. 2,180,396, Nov. 21. A main body portion of a metal of high elec. cond. such as Cu is used with a retaining wall or band of high-strength metal such as Cr encompassing a portion of the main body portion, and a portion of high elec. cond. such as Cu encompassing the wall of high-strength metal.

10—ORGANIC CHEMISTRY

CHAS. A. ROUILLER AND CLARENCE J. WEST

Collected works of Sergei Nikolaevich Naumov. Edited by M. S. El'gort. *Acta Univ. Asiae Mediae*, Ser. VI, *Chemia* Nos. 10-33 (1937). **The life and work of Sergei Nikolaevich Naumov.** M. S. El'gort. *Ibid.* 11-20 (in German, 21-31). **The scientific achievements of Sergei Nikolaevich Naumov.** *Ibid.* 33-48 (in German, 49-65).—24 papers and a portrait are included. E. J. C.

Catalytic hydration of acetylene and of some alkylacetylenes. Raymond E. Schaad and Vladimir N. Ipatieff. *J. Am. Chem. Soc.* **62**, 178-80 (1940).—Hydration of propyne, 1-butyne (I), 1- and 2-pentyne, 1-hexyne and 1-heptyne (II) gives Me_2CO, 2-butanone, 2-pentanone, 2-hexanone and 4-heptanone (III), resp. If the hydrocarbon is liquid, it is dropped simultaneously with water at const. rates from burets into the upper end of a vertical Pyrex tube contg. solid H_3PO_4 catalyst (Ipatieff, U. S. pat. 1,993,512-13, *C. A.* **29**, 2546[5,6]) heated to 204° (I reacts at 150°); if the hydrocarbon is gaseous, it is passed from a weighed Al bomb through a calibrated flowmeter to the top of the catalyst tube. In addn. to the ketone formation there is formed a small quantity of oil with relatively high b. p. and *n* (probably condensation products); some isomerization also occurs; I appears to be changed to the 2-isomer; that II yields III shows that isomerization of II occurs before hydration. C_2H_2 and H_2O at 260–300° give 30–56% of AcH, with about 50% of condensation products (crotonaldehyde and aromatic hydrocarbons); in the case of C_2H_2 the catalyst needs reactivation after some 20 hrs. (heating in dry air at 500° for 16 hrs., followed by steaming at 260° for 16 hrs.). C_2H_2-C_2H_4 and C_2H_2-N mixts. also yield AcH, the C_2H_4 and N acting as diluents. C. J. West

Condensations by sodium. XV. Reactions of disodium compounds with ethylidene and methylene chlorides. Avery A. Morton and John T. Massengale. *J. Am. Chem. Soc.* **62**, 120-3 (1940); cf. *C. A.* **32**, 7437[7].—Amylidenedisodium (I) and $MeCHCl_2$ give 13% of BuCH:CHMe (80% of the max. possible estd. from the $BuCH(CO_2H)_2$ (II) usually obtained by carbonation). CH_2Cl_2 and I give 1-hexene. These reactions are in agreement with the view that I is present as an intermediate from which II is obtained by carbonation. PhNa prepd. from PhCl and Na in petr. ether at 30° and refluxed with PhMe at 52° for 2 hrs. was relatively inactive, carbonation showing that no exchange had occurred (MeI showed the same lack of exchange); if petr. ether is removed so that the b. p. is 85°, there results 26% $PhCH_2CO_2Et$ (III) and 35% $PhCH(CO_2Et)_2$ (IV); at 106° there were formed 17% III and 39% IV; the yields were still lower at higher temps. Exchange of PhNa with PhMe gave low yields when the Na compd. was heated for some time before adding all of the PhMe. Efforts to use this reaction for showing the existence of some benzylidenedisodium (V) along with benzylsodium (VI) as a product of the exchange reaction between PhNa and PhMe were qualitatively successful; styrene from CH_2Cl_2 and methylstyrene from $MeCHCl_2$

were both formed, though the yield was not over 4%. Me_2SO_4 and MeI give approx. the same yield of PhEt (43%) when added to the mixt. of V and VI; in neither case is iso-PrPh found among the products. Use of PhCl instead of AmCl as the source of PhNa gives the same yield but the product is less reactive with PhMe; that from PhCl is a black powder which settles quickly whereas that from AmCl is green and remains in suspension for some time. Attempts to use $PhCH_2Cl$ and $PhCHCl_2$ as sources of mono- and di-Na compds. were unsuccessful, either because the Na compd. formed was too reactive for isolation in the presence of incoming $PhCH_2Cl$ or because little or no reaction occurred with the metal. Behavior of the di-Na compds. with other dihalogen compds. such as $(CH_2)_4Cl_2$ and $PhCHCl_2$ was tried but no evidence of the expected reaction was found. Styrene was not obtained from $PhCH_2CH_2Cl$ and $PhCH_2Na$. **XVI. Formation of decane in the Wurtz reaction.** Avery A. Morton and Graham M. Richardson. *Ibid.* 123–6.—No decane is formed prior to formation of AmNa in the reaction between AmCl and Na. This Wurtz synthesis is divided into 2 distinct phases, that concerned with formation of organometallic compd. and that related to reaction of this intermediate with addn. of alkyl chloride. If free radicals are present in the early phase, their activity is limited to addn. with Na or to disproportionation and combination of the -idene product with 2 atoms of Na to form another organometallic compd. A curve gives the relation of acid and decane yields with changing ratio of Na to AmCl; as the ratio increases, the yield of decane decreases. **XVII. Comments on the formation of triphenylene.** Avery A. Morton, John T. Massengale and Graham M. Richardson. *Ibid.* 126–9.—*o*-$C_6H_4Ph_2$ and Ph_2 are not metallated by PhNa but are by AmNa. Under the conditions in which organometallic compds. are isolated in this work no evidence of metallation of PhCl could be detected. Triphenylene is not formed under the conditions of this work either as a result of metallation of *o*-$C_6H_4Ph_2$ or of PhCl. **XVIII. A study of the possible conversion of amylsodium to amylidenedisodium.** Avery A. Morton and Graham M. Richardson. *Ibid.* 129–31.—Amylidenedisodium (I) frequently is obtained in somewhat higher yields if the mixt. is warmed at 42° or is stirred for a very long time. Simultaneously lower yields of caproic acid are usually found. These results suggest that AmNa is capable of being converted into I but the change is an uncertain one and does not exceed 10% at the most. Active Ni appears to decomp. a portion of the AmNa at 42°. Under appropriate conditions $BuCH(CO_2H)_2$ is 1 of the carbonation products of the reaction of AmCl on Na in C_6H_6 although AmNa is completely removed by the solvent at room temp. Small quantities of C_6H_6 are not quantitatively metallated by AmNa. C. J. West

Chlorine derivatives of aliphatic series. XVI. Vicinal effect. D. V. Tishchenko. *J. Gen. Chem.* (U. S. S. R.) 9, 1380–8(1939); cf. *C. A.* 33, 4190[1,6].—The sapon. rate of aliphatic primary, secondary and tertiary 1,2-, 1,3- and 1,4-dichlorides is studied by heating the compds. in sealed tubes with aq.-alc. 0.1 *N* NaOH at the required temps. (30–100°) for 1–13 hrs. and titrating the cold reaction products with 0.1 *N* NaOH or HCl at definite intervals of time. The compds. tested are: $(CH_2CClMe_2)_2$; $CH_2(CClMe_2)_2$, b_5 51.5°; $(CClMe_2)_2$, m. 159–60°; $(CH_2CHClMe)_2$, b_{12} 62–2.5°, d_4^{13} 1.0529, n_D^{13} 1.4495, M. R.$_D$ 39.53; $CH_2(CHClMe)_2$, b_{761} 142–7°, d_4^{18} 1.0634, n_D^{18} 1.4399; $(CHClMe)_2$, b. 116–17°; $(CH_2CH_2Cl)_2$, b_{762} 155°; $CH_2(CH_2Cl)_2$, b. 120–2°, d_4^{19} 1.204, n_D^{19} 1.452, M. R.$_D$ 25.3; $(CH_2Cl)_2$. Again the tabulated results show that in each series the sapon. velocity decreases from 1,2- to 1,4-dichlorides and between the series from the primary to tertiary. With changes in the NaOH concn. the sapon. rate of tertiary dichlorides is practically unchanged, while that of primary and secondary dichlorides decreases sharply. For understanding of the varied reactivity and magnitude of dipole moments of polysubstituted org. compds. the conception of *"vicinal effect"* is suggested. The latter in the presence of neg. substituents (the valency electronic pair of the link C—X is nearer to X) decreases the dipole moments of the bond C—X and retards the ionization of atoms or the X groups. Pos. substituents (electron pair is closer to C) decrease the moments of the C—X bonds and facilitate the ionization of X groups. The vincinal effect is more pronounced with the greater propinquity of polar substituents and practically disappears at the 1,4-position. Chas. Blanc

Peroxide effect in the addition of reagents to unsaturated compounds. XXIV. The addition of hydrogen iodide to propene, 1-bromopropene, allyl chloride and allyl bromide. M. S. Kharasch, James A. Norton and Frank R. Mayo. *J. Am. Chem. Soc.* 62, 81–6(1940); cf. *C. A.* 34, 369[6].—In a thorough investigation of the addn. of HI to C_3H_6, CH_2:$CHCH_2Cl$ and CH_2:$CHCH_2Br$, only 1 (the "normal") addn. product was obtained in each case. The addn. of HI to 1-bromopropene yields a mixt. of approx. 33% 1,1- and 66% of 1,2-dihalides. It is shown that I is a catalyst for the addn. of HI and that peroxides accelerate this addn. because they liberate I from HI. $MeCHICH_2Cl$ and $EtCHIBr$ have been prepd. in the pure and nearly pure states, resp. C. J. West

1,2- and 1,4-Addition. IV. Nitrogen tetroxide and isobutylene. Arthur Michael and G. H. Carlson. *J. Org. Chem.* 5, 1–13(1940); cf. *C. A.* 33, 5803[6].—The action of N_2O_4 (I) on $Me_2C{:}CH_2$ (II) is investigated under various conditions. When II is treated with I in ether, bis(α,β-nitrosonitric ester) (III) of II does not sep. from the addn. products formed (cf. Sidorenko, *J. Russ. Phys. Chem. Soc.* 38, 955(1906); Wallach, *Ann.* 241, 296 (1888); Strack and Fanselow, *C. A.* 23, 1874). Liquid II, in the absence of a solvent, and I give III in 7–12% yield; in the presence of petr. ether in 0–13% yield. Moderate changes in low temps. do not alter the course of the reaction appreciably, the yield of III being 12% and 7.4%, resp., at −12° and −80°. When I reacts with gaseous II, oily products are obtained which were not further examd. because pronounced oxidation occurs. Unlike the oily product of the expts. carried out in the presence of petr. ether, which readily decomps. and cannot be sepd. into definite fractions, the liquid products from the expts. in ether are relatively stable and can be sepd. under reduced pressure into a blue distillable oil (IV) and a green residual oil. The products obtained in the presence of petr. ether yield with PhSNa in MeOH in addn. to $NaNO_3$ and $NaNO_2$, an oil, b_5 145–7°, which on oxidation with Cr_2O_3 in AcOH or with H_2O_2 in Ac_2O gives β-phenylsulfonyl-α-nitroisobutane (V), m. 89–90°, in addn. to some diphenyl disulfone, m. 193–4°. Although the thioether corresponding to V is probably formed from α,β-dinitroisobutane (VI), this compd. has not been isolated nor has the corresponding diamine been obtained by catalytic reduction of the addn. products formed in ether. Catalytic reduction of the crude oil and of IV gives, in addn. to NH_3, $Me_2CHCH_2NH_2$ which is probably formed chiefly from nitroisobutene and from VI through a series of reactions which also yield diisobutylamine. Reduction of IV gives NH_3 and β-hydroxyisobutylamine in practically equimol. proportions and it is probable that these products are formed from the α,β-nitronitrous ester deriv. (VII) of II. Based on the yields of the reduction products, α-nitroisobutene constitutes 5–12% of the crude addn. product and VII represents 16–23%. Assuming that the isolated diisobutylamine is formed from VI, VI constitutes at least 12% of the crude addn. product. **V. Nitrogen tetroxide and tetramethylethylene.** *Ibid.* 14–23.—The action of I on $Me_2C{:}CMe_2$ (VIII) is studied under various exptl. conditions. In ether almost const. yields (19.6–22%) of 2,3-dinitro-2,3-dimethylbutane (IX) are obtained, while without solvents or in petr. ether, only low yields of IX are formed. The nitric ester of 2-nitro-2,3-dimethyl-3-butanol (X) appears to be formed in variable amts. under all conditions used. In the absence of a solvent and under strong oxidative conditions the yield of X is considerable. X readily combines with IX, forming a double compd. (XI). Under the oxidizing action of an excess of I, all IX is transformed into XI. Accordingly isolation of IX is realized only under conditions tending to depress the oxidizing action of I and the yield of X. The

compn. of XI is deduced from the analytical data and from the relative amts. of NH_3, 2-amino-2,3-dimethyl-3-butanol and tetramethylethylenediamine obtained on catalytic reduction of XI. The possibility of the formation of X is discussed and it is suggested that I may oxidize VIII to the corresponding oxide and then act upon the latter to yield X. It is, however, more probable that X is formed by oxidation of the corresponding nitrosonitric ester which in turn is probably formed primarily by direct addn. of I to VIII. With an excess of VIII and ether, IX is obtained in about 20% yield. Under the oxidizing action of an excess of I, all IX appears to be combined with X to form XI. These results and the compn. of XI indicate that the crude reaction product formed in approx. equimol. amts. consists chiefly of IX and the nitric ester of 2-nitroso-2,3-dimethyl-3-butanol (XII). XII under the oxidizing action of I is converted into X, which combines with IX to XI. The results confirm those of Demianov and Sidorenko (*C. A.* **5**, 2100). The dinitrous ester as found by Schmidt (*Ber.* **36**, 1775(1903); **37**, 546(1904)) has not been observed. F. E. Brauns

Sulfur studies. XV. The synthesis of alkanesulfonic acids and certain derivatives. P. H. Latimer and R. W. Bost. *J. Org. Chem.* **5**, 248(1940); cf. *C. A.* **32**, 911[5].—Alkanesulfonic acids (I) are mostly prepd. by oxidizing mercaptans or disulfides. Hemilian's method modified by Strecker (*Ann.* **148**, 90(1868)) by heating alkyl halides with $(NH_4)_2SO_3$ has so far not been used for the prepn. of I above the pentanesulfonic acid. The following RSO_3H are prepd. by heating the corresponding alkyl halides with a soln. of 2 mols. $(NH_4)_2SO_3$ in an equal wt. of distd. H_2O for several hrs. The mixt. is then dild. and 0.5 mol. $Ba(OH)_2$ is added and the I isolated as their Ba salts. The Ba salts of I are sepd. from the Ba halides by extg. the latter with abs. EtOH in a Soxhlet. The yields of the *Ba salts* and the m. ps. of the *phenylhydrazonium salts* are as follows: R = *Me* 81.6%, 193–4° (decompn.); *Et* 83.0%, 182.8°; *Pr* 89.0%, 204.5° (decompn.); *Bu* 86.5%, 114–15°; *Am* 82.0%, 108–8.2°; C_6H_{13} 68.7%, 101–1.6°; C_7H_{15} 70%, 100–0.5°. The acid chlorides are prepd. according to Sprague and Johnson (*C. A.* **30**, 6703[8]). The *p-toluidides* (II) and *p-phenetidides* (III) are obtained by the action of a slight excess of the sulfonyl chloride on a pyridine soln. of the amine. The yields and m. ps. of the II and III are resp.: R = *Me* (IV) 6.7%, 102.0–2.7°, 54.5%, 126.5–7.4°; *Et* 45%, 80.0–0.5°, 38.4%, 80.4–1°; *Pr* (V) 49.5%, 67.0–7.8°, 61.0%, 101.0–1.5°; *Bu* 58.4%, 74.2–5.2°, 48.5%, 78.2–79°; *Am* 56%, 48.4–9.4°, 34.5%, 69–70°. In addn. to these compds. *o-benzoxyphenyl methanesulfonate*, m. 92–3°, and *β-naphthyl methanesulfonate*, m. 103.5–4.5°, are prepd. in 56% and 50% yield, resp. IV and V are tested for their chemotherapeutic and antipyretic actions and compared with those of phenacetin. F. E. Brauns

α-(Alkylsulfonyl) amides. Austin Pomerantz and Ralph Connor. *J. Am. Chem. Soc.* **61**, 3386–8(1939); cf. *C. A.* **32**, 1672[2]; **34**, 372[4].—α-Bromoamides were prepd. from the crude acid chloride of the α-Br acid and concd. NH_4OH (satd. at 0°), the chloride being added during 3 hrs. and NH_3 being passed through continuously at 0°; *α-bromovaleramide* m. 78.5–9°; *α-bromocaproamide* m. 58.5–9°; the yields are 50–70%. α-(Alkylthio)-amides were prepd. by adding the haloamide in portions with shaking to a soln. of the mercaptan in EtONa at 0°; after 2–5 days at room temp. the reaction is complete; with 0.15 to 0.30 mole of reactants the av. yields are 88%. *α-(Alkylthio)amides:* $EtSCH_2CONH_2$ m. 50.5–1°, $EtSCHMeCONH_2$ m. 65–5.5°, $PrSCHMeCONH_2$ m. 56.5–7°, $BuSCHMeCONH_2$ m. 60.5–1.5°, $EtSCHEtCONH_2$ m. 100.5–1°, $PrSCHEtCONH_2$ m. 78–8.5°, $BuSCHEtCONH_2$ m. 65–5.5°, $EtSCMe_2CONH_2$ m. 93.5–4°, $PrSCMe_2CONH_2$ m. 95–5.5°, $BuSCMe_2CONH_2$ m. 107.5–8°, $EtSCHPrCONH_2$ m. 101.5–2°, $PrSCHPrCONH_2$ m. 98.5–9°, $BuSCHPrCONH_2$ m. 64.5–5°, EtSCH(iso-Pr)-$CONH_2$ m. 111–11.5°, PrSCH(iso-Pr)$CONH_2$ m. 98.5–9°, BuSCH(iso-Pr)$CONH_2$ m. 75–5.5°, $EtSCHBuCONH_2$ m. 84.5–5°, $PrSCHBuCONH_2$ m. 100.5–1°, $BuSCHBuCONH_2$ m. 86.5–7°; *β-(butylthio)isobutyramide*, m. 54.4–5° (54%). *α-(Alkylsulfonyl)amides* were prepd. in an av. yield of 72% by oxidation of the mercapto amides in AcOH-Ac_2O with 30% H_2O_2 at about 0°: $EtSO_2CH_2CONH_2$ m. 98.5–9°, $PrSO_2CH_2CONH_2$ m. 104–4.5°, $EtSO_2CHMeCONH_2$ m. 126–6.5°, $PrSO_2CHMeCONH_2$ m. 122–2.5°, $BuSO_2CHMeCONH_2$ m. 114–14.5°, $EtSO_2$-$CHEtCONH_2$ m. 168–8.5°, $PrSO_2CHEtCONH_2$ m. 137–7.5°, $EtSO_2CMe_2CONH_2$ m. 92.5–3°, $BuSO_2CMe_2CO$-NH_2 m. 99.5–100.5°, $BuSO_2CMe_2CONH_2$ m. 77.5–8°, $EtSO_2CHPrCONH_2$ m. 117.5–18°, $PrSO_2CHPrCONH_2$ m. 125–5.5°, $BuSO_2CHPrCONH_2$ m. 125–5.5°, $EtSO_2CH$-(iso-Pr)$CONH_2$ m. 122–3.5°, $PrSO_2CH$(iso-Pr)$CONH_2$ m. 116–17°, $BuSO_2CH$(iso-Pr)$CONH_2$ m. 126.5–7°, $EtSO_2CHBuCONH_2$ m. 112–12.5°, $PrSO_2CHBuCONH_2$ m. 119–19.5°. The pharmacol. study will be reported elsewhere. C. J. West

Reaction of atomic hydrogen and azomethane. H. Heaikin and H. Austin Taylor. *J. Chem. Phys.* **8**, 1–7 (1940).—At 27° the only reaction between at. H and MeN:NMe is an addn. to the N double bond to produce $MeNHNHMe$ by a mechanism with a max. activation energy of 3–4 kg.-cal. At 110° there is, in addn., a rupture of the C-N bond in MeN:NMe, producing CH_4, and of the N-N bond in $MeNHNHMe$, producing $MeNH_2$. The energy of activation of each rupture is about 8 kg.-cal. At 195° an addnl. reaction is evident, involving assocn. of Me radicals with MeN:NMe. G. M. Petty

The synthesis of pentadecanoic acid. Charles F. Krewson. *Pharm. Arch.* **10**, 88–92(1939).—The following scheme employing the nitrile process for attaching an addnl. C to the chain is used: myristic acid → Bu myristate → myristyl alc. → myristyl bromide or iodide → myristyl cyanide → pentadecanoic acid. The prepn. of Bu myristate, m. 163–5° (90.8% yield), tetradecyl alc. (myristyl alc.) and myristyl bromide and iodide is given in detail. H. M. Burlage

Derivatives of fatty acids of high molecular weight. I. Characterizations of acids. Henry Gilman and Grover M. Ford. *Iowa State Coll. J. Sci.* **13**, 135–47(1939).—See *C. A.* **32**, 4943[1]. F. E. Brown

Preparation of pure stearic acid. J. P. Kass and L. S. Keyser. *J. Am. Chem. Soc.* **62**, 230(1940).—Pure stearic acid, m. 69.6–70.2° (cor.) and dissolving in concd. H_2SO_4 at 70° without discoloration, results in quant. yield by catalytic reduction of linoleic, elaidic or α- or β-eleostearic acid in AcOH at 3 atm. pressure of H at room temp. for 3 hrs. C. J. West

Chlorination of butyl trichloroacetates. Howard M. Waddle and Homer Adkins. *J. Am. Chem. Soc.* **61**, 3361–4(1939).—Bu (I), iso-Bu (II) and *sec*-Bu trichloroacetates (III) were prepd. in 82–9% yields by refluxing 2 moles Cl_3CCO_2H and 4 moles of the alc. for 6–8 hrs. In the chlorination of the esters, 2 moles (440 g.) was heated in the reaction flask to 120°, a 200-w. light bulb was placed 5 cm. from the surface and Cl was passed in at the rate of 15–20 g. per hr. at 120 ± 2° and continued until the wt. corresponded to 2 moles Cl (69.9 g.). Each of the esters gave 2 mono-Cl (approx. 0.5 mole) and a di-Cl deriv. (a few hundredths of a mole); about 0.25 mole of ester was recovered unchanged and about 25% was not accounted for except in intermediate fractions and the distn. residue. Chlorobutanols were obtained from 5 of the 9 Cl esters isolated. The lower-boiling Cl esters from II and III reacted with NaOH much more slowly than in the case of the other 5 esters; approx. 50% was recovered unchanged after several hrs. with 1 mole-equiv. of NaOH; iso-PrCHO was detected among the products from II; with 2 mole-equivs. of NaOH 32 g. of the ester of II gave 5 g. of iso-PrCHO and 4 g. of a glycol (?), b_7 69–70°. The Cl ester from III did not yield products which could be identified. *Trichloroacetates:* I, b_{24} 100–1°, d. 1.266, *n* 1.4495 (all d. and *n* values are for d_4^{20} and n_D^{20}); II, b_{24} 93–4°, d. 1.255, *n* 1.4456; III, b_{19} 88–9°, d. 1.252, *n* 1.4440; *2-chlorobutanol*, b_5 94–6°, d. 1.390, *n* 1.4728; *4-isomer*, b_5 113–16°, d. 1.417, *n* 1.4800; *dichlorobutanol*, b_5 127–31°, d. 1.497, *n* 1.4930; *2-chloro-2-methylpropanol*, b_5 80–1°, d. 1.369, *n* 1.4658; *3-isomer*, b_5 98–9°, d. 1.397, *n* 1.4742; *3-chlorobutan-2-ol*, b_5 83–4°, d. 1.378, *n* 1.4671;

1(?)-isomer, b_5 91–3°, d. 1.395, *n* 1.4713; *dichlorobutan-2-ol*, b_5 108–10°, d. 1.475, *n* 1.4850; *dichloro-2-methylpropanol*, b_5 101–5°, d. 1.477, *n* 1.4862; *2-chlorobutanol*, b_{28} 74–6°, d. 1.062, *n* 1.4410 (*phenylurethan*, m. 52.5–3.5°); *4-isomer*, b_{10} 72–5°, d. 1.125, *n* 1.4551 (*phenylurethan*, m. 54–5°); *dichlorobutanol*, b_8 87–93°, d. 1.273, *n* 1.4786; *3-chloro-2-methylpropanol*, b_{21} 76–8°, d. 1.083, *n* 1.4460 (*phenylurethan*, m. 63.5–4°); *1(?)-chlorobutan-2-ol*, b_{27} 68–70°, d. 1.068, *n* 1.4410 (*phenylurethan*, m. 78.5–9°). C. J. West

Preparation of acetyl bromide. Theodore M. Burton and Ed. F. Degering. *J. Am. Chem. Soc.* **62**, 227(1940).—AcBr is prepd. in 71.4–3.4% yields by adding slowly through the dropping funnel, with stirring, a slight excess of 99.5% AcOH (3.075 mols.) to 1 mol. of PBr_3; purified PBr_3 gives only 74.9% of AcBr; addn. of PBr_3 to an excess of boiling Ac_2O gives 81.7% of AcBr. C. J. West

Ketene and its dimer. Charles D. Hurd and Arthur S. Roe. *J. Am. Chem. Soc.* **61**, 3355–9(1939).—Ketene (I) reacts with *tert*-BuOH, *tert*-AmOH and PhOH, with concd. H_2SO_4 or *p*-$MeC_6H_4SO_3H$ as catalyst, to give approx. 90% of their acetates. In the presence of AcOK I reacts with acrolein, crotonaldehyde, HCHO and HCO_2Me to give complex products of high mol. wt.; the reactions occur even at −80°. I and HCO_2H give HCO_2Ac, b_{19} 33–3.5°, n_D^{19} 1.3940, d_4^{20} 1.1458; with $PhNH_2$ this gives PhNHCHO. Acetylketene (II), b_{28} 43–3.1°, has d^{25} 1.0817, γ^{25} 33.89, *P* 188; II displays 23% enolization toward iso-PrMgCl; the liberated gases contain 1.8 and 21.8% (by vol.) of C_3H_8 and C_4H_8. Heating 51.4 g. of II at 650° gives 19.8 g. I and 12.6 g. unchanged II. II (15.7 g.) and BzH give 8.38 g. of PhCH.CHAc. II and Et_2Zn in C_6H_6 or PhMe give a yellow solid that yields nothing but tars on hydrolysis or on reaction with BzCl. C_3O_2 does not react with BzH. C. J. West

Reduction of certain simple and substituted acid amides. I. Electroreduction of cyclic and open-chain peptide groups. N. I. Gavrilov and A. V. Koperina. *J. Gen. Chem.* (U. S. S. R.) **9**, 1394–1401(1939).—Studies of Tafel (*Ber.* **34**, 258, 1181(1901)) and Kindler (*C. A.* **21**, 2669) on the electrolytic reduction of org. acid amides are extended to the investigation of the reduction mechanism of the CO group in the CO-NH link in aliphatic and aromatic acid amides and their *N*-substituted alkyl, aryl, acyl and peptide derivs. The reduction was carried out in a closed porous cell with Pb electrodes (cf. Tafel, *Ber.* **33**, 2209(1900)) at 40° and 9 amp. and 120 v. (c. d. 0.187 amp./sq. cm.). The electrolysis was continued until the absorption of H in the cell had stopped (about 2 hrs.). The detn. of unabsorbed H was made at intervals of 5 min. The rate of H absorption, as well as the kinetics of reduction, was calcd. from the difference in the vol. of residual H formed during the electrolysis with and without the presence of the substance under investigation. The cathode soln. was prepd. by dissolving 0.01 mol. of the substance in a mixt. of 40 ml. H_2O, 30 ml. alc. and 5 ml. of concd. H_2SO_4. Greater proportions of H_2O or alc. were used for poorly sol. compds. $BzNPh_2$ was treated in an AcOH medium. A 20% H_2SO_4 soln. was used as the anode liquid. With some expts. the reaction products or the unaltered substances in the cathode soln. were isolated and identified. The following compds. failed to react: $PhCH_2CONH_2$ (I) and its *N*-Ph (II) and *N*-di-Ph (III) derivs.; $HCONH_2$; $AcNH_2$ and $AcNPh_2$; $EtCONMe_2$ (IV) and $EtCONPh_2$ (V); $Me_2CHCONMe_2$ (VI) and $Me_2CHCONPh_2$ (VII); $Me_3CCONMe_2$ (VIII); phenaceturic acid (IX); acetyl(*N*-phenyl)glycine, $AcNPhCH_2CO_2H$; acetylglycine and dimethyl- (X) and trimethylacetylglycine (XI); glycylglycine and glycylalanine. $PhCH_2CONHMe$ (XII) was reduced 40.2, $HCONMe_2$ (XIII) 52.7, $HCONPh_2$ (XIV) 55.8, $AcNHPh$ (XV) 55, $AcNPh_2$ (XVI) 66 and diketopiperazine 40%. $PhCONH_2$ and its *N*-Me and *N*-di-Me derivs., $PhCH_2CONMe_2$ (XVII), phenylacetopiperidide, $(PhCH_2CON.(CH_2)_4.CH_2)$ (XVIII), and hippuric acid (XIX) were reduced 96–100%. The tentative results show that in the aromatic amides the cathodic reduction of the CO group is only possible when it is directly linked with the aryl radical. The removal of the two even by 1 C atom inhibits the reduction (I and IX). The reactivity of I was successively increased with the substitution of 1 and 2 H atoms in the amido group (XII and XVIII). The same effect was produced by piperidine (XVIII). The introduction of Ph radical caused no increased reactivity (II and III). The aliphatic acid amides as a rule were inactive. The reactivity of $HCONH_2$ and $AcNH_2$ was increased by the introduction of Me and Ph radicals into the amido group (XIII, XIV, XV and XVI). $EtCONH_2$, iso-$PrCONH_2$ and Me_3CCONH_2 and their *N*-substituted Me and Ph derivs. are incapable of reduction (IV, V, VI, VII and VIII). Of the acylated amides only XIX was reduced. X was prepd. when 15 g. iso-PrCOCl was slowly introduced into 11 g. glycine and 30 g. of anhyd. K_2CO_3 in 100 ml. Et_2O and boiled 1–2 hrs. The residue from the ether, after the addn. of excess HCl, was extd. with ether and the ether expelled, giving white crystals, m. 103–4°. XI, m. 134–5°, was similarly prepd. in 26% yield from Me_3CCOCl. Chas. Blanc

3-Nitrophthalates of the monoethers of ethylene and diethylene glycol. A. J. Veraguth and Harvey Diehl. *J. Am. Chem. Soc.* **62**, 233(1940).—*3-Nitrophthalates* of $HOCH_2CH_2OR$ were prepd. by boiling the ether with the anhydride 15 min. after soln. resulted (if the b. p. is above 150°, PhMe is added); the oily layer is washed with hot H_2O and the deriv. crystd. from H_2O contg. sufficient EtOH for soln.; *Me* m. 128.4 9°; *Et* m. 118–8.6° (*monohydrate*, m. 94.2–4.5°); *Bu* m. 120–20.6° (121–20.6° given); *Ph* 112–13°; benzyl, an oil. The *3-nitrophthalate* of the mono-Me ether of diethylene glycol m. 87 90° (monohydrate) or 91.4–2.2° (anhyd.); the derivs. of the Et and Bu ethers are oils. C. J. West

Structure of the mixed polymer of butadiene and acrylonitrile. E. N. Alekseeva. *J. Gen. Chem.* (U. S. S. R.) **9**, 1426–30(1939).—An equimol. mixt. of butadiene (I) and acrylonitrile (II) contg. 1% BzO_2H was polymerized at 60° for 116 hrs. and the product was vacuum-distd. at room temp. II in the polymer was detd. by the Kjeldahl method. The polymer was ozonized and oxidized with H_2O_2 by the method of Pummerer, *et al.* (*C. A.* **30**, 4044[3]). The resulting carboxylic acids were methylated with abs. MeOH contg. 10% HCl and the distn. fractions analyzed, giving succinic, butanetricarboxylic, hexanetetracarboxylic and dodecanepentacarboxylic acids in definite proportions, indicating that about one-half of the polymerization product is formed by the alternate succession of I and II in the mol. About one-third of the polymer consists of the mols. in which 1 I unit corresponds to 2 or 3 mols. of II. Chas. Blanc

Cyclic methyleneimines. II. Hydrolysis of quaternary compounds and preparation of aliphatic secondary amines. Raymond Blundell and John Graymore. *J. Chem. Soc.* **1939**, 1787–9; cf. *C. A.* **33**, 1337.—*N,N',N''*-Trimethyltrimethylenetriamine (I) (from $MeNH_2$ and HCHO) and EtI at 0° after 12 hrs. give the *ethiodide*, m. 72° (decompn.); distn. with NaOH gives $MeNH_2$ and MeEtNH. The *propiodide* of I m. 105° (decompn.); NaOH gives $MeNH_2$ and MePrNH (*2,4-dinitrophenyl deriv.*, orange, m. 72–3°). MePrNH and HCHO in H_2O, made alk. with NaOH, give *methylenebismethylpropylamine*, b. 170–1°, d_4^{19} 0.795. The *butiodide* of I m. 123 5° (decompn.); on standing the product showed a high I content (presence of II). Hydrolysis by evapn. with HCl gives $MeNH_2$.HCl, Me_2BuN and MeBuNH (HCl salt, m. 171°; *2,4-dinitrophenyl deriv.*, golden, m. 81°). I forms a *complex* with NaI and a *diiodide* (II), m. 162°, with I. EtCl, PrCl and BuCl do not react with I; iso-PrI gives a very poor yield of a reaction product. C. J. West

Catalytic action of *p*-toluenesulfonic acid on acetylene γ-glycols. I. The action on 2,5-dimethyl-3-hexyne-2,5-diol and 3,6-dimethyl-4-octyne-3,6-diol. A. Babayan. *J. Gen. Chem.* (U. S. S. R.) **9**, 1410–11(1939).—Preliminary expts. showed that acetylene γ-glycols react with *p*-$MeC_6H_4SO_3H$ (I) by cleaving 2 mols. H_2O and forming corresponding divinylacetylenes. Thus, the distn. of 4.9

g. 2,5-dimethyl-3-hexyne-2,5-diol with 0.07 g. I at 140–60° gave 91.1% *divinylacetylene*, b. 117–20°, b_5 35°. Under similar conditions 3,6-dimethyl-4-octyne-3,6-diol (3.14 g. and 0.08 g. I) yielded 90% *1,2,5,6-tetramethyldivinylacetylene*, b_{680} 160–7°. Chas. Blanc 1

Constituents of the plants of Veronica species. Hukuziro Huzikawa, Yutaka Kudo and Hirosi Sengoku. *J. Pharm. Soc. Japan* **59**, 611–14(in German, 241–2)(1939). —The mannitol content of 8 species of *Veronica* ranged from 0.15 to 0.74%. The mannitol was identified as the hexa-Ac, tribenzylidene, or triformal deriv. F. I. N. 2

Synthesis of amino acids from benzoylaminomalonic ester. E. P. Painter. *J. Am. Chem. Soc.* **62**, 232–3 (1940).—P. confirms the use of $BzNHCH(CO_2Et)_2$ for the synthesis of amino acids as reported by Redemann and Dunn (*C. A.* **33**, 9285[1]); in addn. to those previously prepd. norleucine, α-amino-γ-phenoxybutyric acid and the lactone of α-amino-γ-hydroxybutyric acid have been obtained in good yields. The ester did not give condensation products with CH_2Br_2, $C_2H_4Br_2$ and $C_2H_4Cl_2$ with the proper halogen content, and the desired amino acids could not be isolated after hydrolysis. The use of anhyd. reagents in alkylation of the ester should be emphasized. C. J. West 3

Racemization of amino acids and dipeptides on acetylation with ketene. Wm. M. Cahill and Irving F. Burton. *J. Biol. Chem.* **132**, 161–9(1940); cf. *C. A.* **33**, 1317[3].—*l*(−)-Leucine and *l*(+)-glutamic acid when acetylated with ketene give either the active or racemic *N*-Ac deriv., depending upon the conditions employed. Racemization occurs only when the pH of the soln. is on the acid side of neutrality. Both glycyl-*l*(−)-leucine and *l*(−)-leucylglycine give the corresponding active Ac deriv. but when acetylated under racemizing conditions the former gives a completely racemized deriv. and the latter under the same exptl. conditions yields acetyl-*l*(−)-leucylglycine of max. optical activity. Similar results are obtained with Ac_2O under the proper conditions. This selective racemization may serve as a convenient tool for identifying terminal amino acids in peptides. A. P. Lothrop 4

Synthesis and properties of isocysteine and isocystine. Alfons Schöberl and Hans Braun. *Ann.* **542**, 274–91 (1939).—β-Alanine and o-$C_6H_4(CO)_2O$, heated at 160° for 1 hr., give 85% of *N*-phthalyl-β-alanine, m. 150–1°; Br and red P give 90% of the α-Br deriv. (I), m. 169–71°; Me ester, m. 103–4° (Gabriel, *C. A.* **2**, 1442, gives 52–3°); refluxing I with 48% HBr for 10 hrs. gives 82% of α-bromo-β-alanine-HBr (II), m. 188–90°; *Me ester-HCl*, m. 123–5° (decompn.). II (5 g.) in 8 cc. H_2O, neutralized with 22 cc. *N* NaOH and treated with 12 cc. Na_2S_2 (contg. 325 mg. polysulfide S), satd. with N_2 and allowed to stand in N atm. for 12–15 hrs. at room temp., shaken with animal charcoal, filtered, reduced to half its vol. under H *in vacuo*, acidified with 30 cc. concd. HCl, reduced with 4 g. Sn, dild. to 400 cc., treated with H_2S to remove the Sn and evapd. to dryness, gives 54.8% of isocysteine-HCl (III) (purified through the mercaptide), m. 137–9°. While III can be oxidized by H_2O_2 in aq. soln. contg. $FeSO_4$, isocystine (IV) is obtained cryst. by oxidation of 1 g. III in 4 cc. H_2O with 0.8 g. I in 36% yield (as the HI salt), m. 189–91°; NH_4OH gives 96.4% of free IV, m. 185° (decompn.). III and IV can be detd. colorimetrically by the use of phosphotungstic acid. $ClCH_2CH(OH)CO_2H$ (30 g.) and 300 cc. NH_4OH (satd. at 0°), heated 4 hrs. at 100°, give isoserine; o-$C_6H_4(CO)_2O$ at 160° gives 97.5% of *phthalylisoserine*, m. 196–7° (cor.); *Me ester* (V), m. 106–8° (cor.), 94.5% yield with MeOH and HCl; AcCl gives 100% of the *O-Ac deriv.* of the ester, m. 135–7° (cor.). Refluxing 21 g. V and 42 g. PCl_5 in 450 cc. C_6H_6 for 30 hrs. gives 49% of *α-chloro-β-phthalylalanine Me ester* (VI), m. 119–20°; if $CHCl_3$ is used as the solvent, the by-product, *N-phthalylisoserine monophosphate*, m. 188–9° (cor.), is isolated. Refluxing VI with 20% HCl for 5 hrs. gives 75.7% of *α-chloro-β-alanine-HCl*, m. 134–5°; from this III is prepd. as from II. The degradation products from IV and dithiodiglycolic acid (VII) treated with *N* NaOH at 50° and 100° and with *N* H_2SO_4 and H_2O at 100° are given; VII is stable to *N* H_2SO_4 after 12 hrs. at 100°; IV gives NH_3 only with *N* NaOH at 100° and gives SS only with H_2O (in 15.9% yield) and with *N* H_2SO_4 (in 32.6% yield). C. J. West 5

Structure of alginic acid. I. E. L. Hirst, J. K. N. Jones and Winifred O. Jones. *J. Chem. Soc.* **1939**, 1880–5; cf. *C. A.* **33**, 9287[6].—Two samples of Na alginate (I) were used, having $\eta_{sp.}/c$ 33.3 and 12.4 for c 1; both had $[\alpha]_D^{25}$ 139° (H_2O, c 1). The free acid (II) gave 21% furfural and had an equiv. wt. of 182 (titration with 0.1 *N* NaOH); the yield of CO_2 on boiling with 12% HCl was 70% of the theory, owing to the stability toward acid reagents. II is almost unaffected by boiling dil. HCl, H_2SO_4 or HNO_3; heating with H_2O at 150° led to little if any autohydrolysis. I, II or the Me ester of II could not be acetylated by Ac_2O and C_5H_5N or $ZnCl_2$; HI led to degraded products. Hot dil. alkali rapidly degraded II with the formation of orange decompn. products; thus, the methylation of II by Me_2SO_4 and 30% NaOH was unsatisfactory even when carried out in an O-free atm. II formed an insol. Tl deriv., which reacted slowly and incompletely with MeI and gave even less satisfactory results with Me_2SO_4. Therefore, a degraded II was prepd. by boiling 50 g. I with 400 cc. 10% MeOH-HCl for 17 hrs.; this acid (III) was obtained in a yield of 25 g.; it was sol. in H_2O, had $[\alpha]_D^{25}$ −134° (H_2O, c 1.6), and gave 20.4% furfural and 86.6% of uronic anhydride; the equiv. wt. was 203. The filtrate from III, neutralized with Ag_2CO_3, filtered, evapd., extd. with cold MeOH, evapd. to dryness with 600 cc. *N* TlOH and boiled with MeI for 2 days, extd. with MeOH and further methylated with MeI and Ag_2O, yielded 20.2 g. of a sirup, giving 1.9 g. of Et_2O-insol. solid and 18.3 g. of Et_2O-sol. sirup, 15 g. of which was the *Me ester*, $b_{0.002}$ 147° (bath temp.), n_D^{25} 1.4580, $[\alpha]_D^{25}$ 60° (H_2O, c 10), of *trimethylmannuronic acid*, pale-green viscid sirup, $[\alpha]_D^{25}$ 36.4° (H_2O, c 1.62); oxidation with Br gave a mixt. of 2,3,4-trimethyl-*d*-mannosaccharolactone Me ester and Me 2,3,4-trimethyl-*d*-mannosaccharate. Methylation of III as the Tl salt with MeI, followed by Purdie's reagents, gave a product exceptionally stable to acids; it was recovered unchanged after heating with 3% MeOH-HCl at 90° or 2% MeOH-HCl at 120° for 24 hrs. Boiling with 50% HNO_3 for 18 hrs. gave *meso*-dimethoxysuccinic acid; this indicates that in each of the mannuronic acid residues the Me groups were attached either to C_2 and C_3 or C_4 and C_5. Hydrolysis of the methylated III by heating with 4% MeOH-HCl at 150° for 24 hrs. gave the *Me ester* of *2,3-dimethylmethyl-d-mannuronide*, $b_{0.005}$ 180°, n_D^{25} 1.4650, $[\alpha]_D^{25}$ 59° (H_2O, c 2); hydrolysis gave 2,3-dimethyl-*d*-mannuronic acid (IV), $[\alpha]_D^{25}$ 30° (MeOH, c 1.5), 33° in 2% MeOH-HCl, unchanged after 12 hrs. Oxidation of IV with Br at 30° for 6 hrs. gave 2,3-dimethyl-*d*-mannosaccharic acid, $[\alpha]_D^{25}$ 16° (H_2O, c 4.2), −7.5° (alkali, c 2.1); this was oxidized by HIO_4 to $OHCCO_2H$ and $HO_2CCH(OMe)CH(OMe)CHO$, and further oxidized to $(MeOCHCO_2H)_2$. Thus, the major portion of the I mol. is composed of β-*d*-mannuronic acid residues; reasons are given for the view that I contains solely pyranose residues which must in this case be linked through C_1 and C_4. C. J. West 6

Condensation brought about by bases. VIII. The conversion of ethyl benzoyldimethylacetate to ethyl benzoate and ethyl isobutyrylisobutyrate in the presence of sodium ethoxide and triphenylmethane. The reversibility of the Claisen type of condensation. Charles R. Hauser and Boyd E. Hudson, Jr. *J. Am. Chem. Soc.* **62**, 62–6(1940); cf. *C. A.* **34**, 988[7].—$BzMe_2CCO_2Et$ (I) on standing in Et_2O with EtONa and Ph_3CH for 5 days at room temp. is completely decompd. into BzOEt and $Me_2CHCOCMe_2CO_2Et$ (II). That at least most of the II thus formed from I is in the form of its enolate is shown by the action of $Me_2CHCOCl$ on the reaction mixt., which results in the formation of 32% of *Et 2,2,4,4,6-pentamethyl-3,5-diketoheptanoate*, b_{18} 136–8°; cyclization gives hexamethylphloroglucinol. That the proton donor (Ph_3CH) is necessary for the conversion of I is shown by the fact that the I is recovered unchanged after standing for 5 days with EtONa in Et_2O; stronger proton donors, such as H_2O or EtOH, cause I to be cleaved to acids or 7 8 9

esters. $AcCMe_2CO_2Et$ with EtONa gives Me_2CHCO_2Et, $AcCH_2COCMe_2CO_2Et$ (III) and some AcOEt; it is assumed that the ester is cleaved to form AcOEt and the Na enolate of Me_2CHCO_2Et; the latter immediately enolizes the unchanged ester, which then condenses with AcOEt, giving III. These results illustrate the reversibility of the Claisen type of condensation. The mechanisms of these reactions are discussed. C. J. West

meso-**Methyltetradecylsuccinic acid.** Mitizo Asano and Tiaki Azumi. *J. Pharm. Soc. Japan* **59**, 605–6 (in German, 214–16) (1939).—A mixt. of 50 g. palmitic acid and 4 g. P was heated with 80 g. dry Br at 70–90° for 5 hrs., followed by heating for 4 hrs. more with 20 g. addnl. Br. About 200 cc. dry alc. was added slowly, with cooling, and the mixt. was heated for 1 hr. and cooled. The reaction mixt. was then extd. with ether, washed with a Na_2CO_3 soln. and evapd. to dryness. The oil was then distd., which gave 47 g. Et α-bromopalmitate (I), b_3 190–200°. Et methylmalonate (9 g.) in 15 cc. alc. and 1.2 g. Na and 18 g. I when heated at 130–40° for 9 hrs. gave 18 g. ester, b_4 220–30°, which on hydrolysis gave heptadecane-2,2,3-tricarboxylic acid (II), $C_{17}H_{32}(CO_2H)_3$, decomp. 127°. II (2 g.) when heated at 130–40° for 3 hrs. gave a compd., m. 90–5°, which when boiled with 20 cc. 5% alkali for 30 min. gave, after acidifying, *meso*-α-methyl-α′-tetradecylsuccinic acid, $C_{17}H_{34}(CO_2H)_2$, m. 98–101°. F. I. N.

Ionization constants and hydrolytic degradations of cyameluric and hydromelonic acids. C. E. Redemann and H. J. Lucas. *J. Am. Chem. Soc.* **61**, 3420–4 (1939); cf. Pauling and Sturdivant, *C. A.* **32**, 2087[2].—Improved methods are given for the prepn. of melon (I), its K and Na salts, and cyameluric acid (II) and its K and Na salts. Titration of the K salts of I and II, using the glass electrode, shows that hydromelonic acid (III) is much stronger than II; values of K_1, K_2 and K_3 are: III, large, 3.16×10^{-3}, 1.26×10^{-6}; II, 1×10^{-3}, 6.30×10^{-7}, 1.12×10^{-9}. Hydrolysis of III with 6 *N* HNO_3 (gently boiled for 1.5 hrs.) gives 72.5% of cyanuric acid (IV); hydrolysis of II gives 93.5% of IV. The titration data and results of hydrolysis indicate that the mols. of these 2 acids contain the planar cyameluric nucleus of P. and S. C. J. West

Thiourea complex salts of lead and thallium. C. Mahr and Hertha Ohle. *Ann.* **542**, 44–8 (1939).—A concd. soln. of $PbCO_3$ in $HClO_4$ (contg. 20% of free acid), treated with an equal vol. of $CS(NH_2)_2$ (I) (cold satd. soln.), gives the *complex* $Pb(ClO_4)_2.6I$, needles, easily sol. in H_2O; $Pb(ClO_3)_2.6I$, yellow, sol. in H_2O. $TlClO_4.4I$, needles, which may be recrystd. from H_2O; $TlClO_3.4I$, cryst. ppt. C. J. West

Exchange reaction of the oxygen atom between glucose or fructose and water. Tosizo Titani and Kokiti Goto. *Proc. Imp. Acad.* (Tokyo) **15**, 298–9 (1939).—The work of Koizumi and Titani (*C. A.* **33**, 4555[6]) on the exchange of one O in glucose for O^{18} is confirmed, and similar results are obtained with fructose (100 hrs. at 55° or 9–20 hrs. at 100°). C. J. West

Pectic substances. IV. Citrus araban. G. H. Beaven, E. L. Hirst and J. K. N. Jones. *J. Chem. Soc.* **1939**, 1865–8; cf. *C. A.* **33**, 4203[8].—Com. citrus pectin, used in this work, contained about 78% Me pectate, 7% araban (I), galactan and smaller amts. of other materials, including hesperidin (II). Preferential soln. of the araban occurs when the pectin is boiled with 70% EtOH; 3 extns. of 1 kg. give 10 g. II and 26 g. I, $[\alpha]_D^{19}$ −34° in H_2O; soln. of I in H_2O and pptn. with Me_2CO give I with $[\alpha]_D^{19}$ −118° in H_2O (about 70% pure); the impurities are removed by acetylation, 8 g. crude I giving 4.2 g. of di-Ac deriv., $[\alpha]_D^{19}$ −94° (Me_2CO). I undergoes hydrolysis with hot 0.01 *N* H_2SO_4 at a rate that indicates the presence of arabofuranose mols. in the polysaccharide; the rate is similar to that of apple and peanut arabans under the same conditions. I is methylated by heating the Tl deriv. with MeI; 10 g. I ($[\alpha]_D$ −80°) give 3.9 g. of a Me deriv., pale-brown, crisp solid with $[\alpha]_D^{19}$ −128° (MeOH); hydrolysis yields an equimol. mixt. of 2,3,5-trimethyl-*l*-arabofuranose, 2,3-dimethyl-*l*-arabinose and 3-methyl-*l*-arabinose; details are given of the identification of these sugars. The structural problem is therefore the same as that discussed in connection with the apple and peanut arabans; the higher rotation of the Me deriv. is believed not to indicate a difference in structure but to be due to the difficulty of sepg. the araban and pectic acid. C. J. West

Agar-agar. II. The isolation of derivatives of 3,6-anhydro-*l*-galactose from agar and the synthesis of their enantiomorphs. I. A. Forbes and E. G. V. Percival. *J. Chem. Soc.* **1939**, 1844–9; cf. *C. A.* **32**, 1214.—The isolation of the anhydro sugar has been reported in *C. A.* **33**, 1673[7], 2110[3]. Methylation of 2.4 g. of 3,6-anhydro-α-methyl-*d*-galactoside gives 2.3 g. of the *2,4-di-Me deriv.* (I), $b_{0.01}$ 90.5°, n_D^{15} 1.4641, n_D^{19} 1.4412, $[\alpha]_D^{19}$ 87° ($CHCl_3$, *c* 0.9), $[\alpha]_D^{19}$ 75° (H_2O, *c* 0.5); in *N* H_2SO_4 (*c* 1.2) $[\alpha]_D^{19}$ changes from 72° to 22° in 24 hrs.; the free sugar does not crystallize, $[\alpha]_D^{19}$ 14° ($CHCl_3$, *c* 1.3), 21° (H_2O, *c* 1.2). 2,3,4-Triacetyl-6-tosyl-α-*d*-galactosyl 1-bromide, shaken with Ag_2CO_3 in abs. MeOH for 15 hrs., gives *triacetyl-6-tosyl-β-methyl-d-galactoside*, a glass, $[\alpha]_D^{19}$ −3° ($CHCl_3$, *c* 1.5); titration in EtOH with *N* NaOH gives a *compd.*, $C_7H_{12}O_5$, m. 118°, $[\alpha]_D^{19}$ −114° (H_2O, *c* 0.7); methylation gives *2,4-dimethyl-3,6-anhydro-β-methyl-d-galactoside* (II), m. 82°, $[\alpha]_D^{19}$ −77° (H_2O, *c* 0.6), −86° (H_2O, *c* 0.5). I in MeOH ($[\alpha]_D^{19}$ 98°) and 7% MeOH-HCl gives II (const. rotation after 2 hrs.). II with *N* H_2SO_4 for 18 hrs. at 24 hrs. gives 2,4-dimethyl-3,6-anhydro-*d*-galactose, which forms an *anilide*, m. 118°, $[\alpha]_D^{19}$ 100° (EtOH), changing to 56° in 1 day; the amide (III) m. 150°, $[\alpha]_D^{19}$ 75° (H_2O, *c* 1). The lactone with 3% MeOH-HCl at 70° for 6 hrs. gives *Me 2,4-dimethyl-3,6-anhydro-d-galactonate* (IV), m. 49–50°, $[\alpha]_D^{18}$ 63° (H_2O, *c* 0.6), 73° ($CHCl_3$, *c* 0.6); it readily yields the above amide. The *l*-isomer of III m. 151°, $[\alpha]_D^{19}$ −74° (H_2O, *c* 0.7); the intermediate lactone $b_{0.01}$ 135° (30% of free acid), $[\alpha]_D^{19}$ −27° (H_2O, *c* 1), changing to −37° in 7 days and to −54° on heating at 80° for 24 hrs. (the equil. soln. contains 20% lactone). The *l*-isomer of IV $b_{0.02}$ 125°, m. 48–9°, n_D^{19} 1.4615, $[\alpha]_D^{19}$ −64° (H_2O, *c* 0.6), $[\alpha]_D^{19}$ −72.5° ($CHCl_3$, *c* 0.6). The natural product is therefore the *l*-isomer. The oil from the sepn. of the *l*-isomer on hydrolysis and treatment with $PhNH_2$ yields several crops of tetramethyl-*d*-galactose anilide but no other recognizable substance. 3,6-Anhydro-α-methyl-*d*-galactoside and the *l*-isomer of II on treatment with 6% H_2SO_4 for 3 hrs., followed by neutralization with $BaCO_3$, yield a small quantity of a resin, similar to that obtained when methylated agar is so treated, and a Ba salt (10–20%) which gives an immediate ppt. of CHI_3 in the cold with NaOI (levulinic acid formation). The yield of levulinic ester (16%) produced by the hydrolysis of methylated agar is of the same order as that estd. for the anhydro-*l*-galactose. It is concluded that the 3,6-anhydro-*l*-galactose units are preformed in agar. C. J. West

3,4-Dimethylgalactose. J. S. D. Bacon and D. J. Bell. *J. Chem. Soc.* **1939**, 1869–71.—3,4-Isopropylidene-β-methylgalactoside (8 lots of 2 g. each) in 40 cc. dry $CHCl_3$ and 70 g. N_2O_5 in 250 cc. $CHCl_3$, cooled with ice for 5 min., poured into ice water, shaken and the $CHCl_3$ soln. run into $KHCO_3$, give 14 g. of the *2,6-dinitrate* (I), m. 79°, $[\alpha]_D^{19}$ 40° ($CHCl_3$, *c* 10); some *β-methylgalactoside 2,3,4,6-tetranitrate*, m. 114–15°, $[\alpha]_D^{19.5}$ −12.4° ($CHCl_3$, *c* 4), $[\alpha]_D^{19.5}$ −7.1° (EtOH, *c* 7.1), was also formed; this was also prepd. from β-methylgalactoside and N_2O_5 in $CHCl_3$. Heating 15 g. I with 110 ml. Me_2CO contg. 5 ml. *N* HCl for 4 hrs. gives 10 g. of *β-methylgalactoside 2,6-dinitrate* (II), m. 110–11°, $[\alpha]_D^{19}$ 15.2° (EtOH, *c* 5). Repeated methylation of 10 g. II (MeI and Ag_2O in Me_2CO at 45°) gives 6.5 g. of the *3,4-di-Me deriv.*, m. 75–6°, $[\alpha]_D^{21}$ −13.3° ($CHCl_3$, *c* 6.5); refluxing this in 10 cc. EtOH with 35 ml. of 30% NaOH satd. with H_2S for 30 min., removal of the EtOH, addn. of K_2CO_3 and extn. with $CHCl_3$ give 3.5 g. of *3,4-dimethyl-β-methylgalactoside* (III), m. 102–3°, $[\alpha]_D^{19}$ −9.1° ($CHCl_3$, *c* 6.2). Refluxing 2.6 g. III with *N* HCl for 4 hrs. gives 2 g. of *3,4-dimethyl-β-galactose* (IV), m. 164–6°, $[\alpha]_D^{19}$ 95°, changing to 116.5° in 20 hrs. (0.6546 g. in 10 cc. H_2O); another sample changed from 95.7 to 117.1° in 16 hrs. (0.2220 g. in 10 cc. H_2O). IV

in MeOH-HCl showed little change in rotation in 2 days, an indication that position 4 is methylated. Oxidation of IV with Br (5 days at room temp. and 2 days at 40°) gives *3,4-dimethylgalactonolactone*, not crystd., $[\alpha]_D^{25}$ 89°, changing to 7° in 5240 min.; MeOH-NH_3 gives a poor yield of the *amide*, m. 172–4°; since this reacts with Na-OCl to form a cyanate, position 2 must be free. C. J. West

2,3,4-Trimethylmannose. W. N. Haworth, E. L. Hirst, F. Isherwood and J. K. N. Jones. *J. Chem. Soc.* **1939**, 1878–80.—A compd. (I), provisionally designated 2,3,4-trimethyl-*d*-mannose (II), has been isolated from the hydrolysis of methylated mannocarolose (*C. A.* **29**, 5419[8]) and of methylated yeast mannan (*C. A.* **31**, 5331[2]). Synthesis of II now shows that I differs markedly from it. α-Methyl-*d*-mannoside gives a 6-trityl deriv. (Watters, *et al.*, *C. A.* **33**, 6251[9]); the tri-Me deriv. m. 106–10°, $[\alpha]_D^{25}$ 33° ($CHCl_3$, *c* 1.04); hydrolysis of 12 g. by boiling in 100 cc. glacial AcOH with the gradual addn. of 40 cc. H_2O gives 6.62 g. of *2,3,4-trimethyl-α-methyl-d-mannoside*, $b_{0.005}$ 150° (bath temp.), n_D^{25} 1.4605, $[\alpha]_D^{25}$ 38° (*N* HCl, *c* 3.9); hydrolysis with 2 *N* HCl gives 6.1 g. of II, n_D^{25} 1.4715, n_D^{25} 1.4705, $[\alpha]_D^{25}$ 2° (H_2O, *c* 5.9); it does not yield a cryst. anilide or phenylhydrazone. Oxidation of 6 g. II in 10 cc. H_2O with 10 cc. Br at 40° for 14 hrs. gives 5.9 g. sirupy lactone, n_D^{25} 1.4730; esterification with 3% MeOH-HCl and heating the ester at 160° and 0.005 mm. gives *2,3,4-trimethyl-d-mannonolactone*, $b_{0.005}$ 160°, n_D^{25} 1.4750; *monohydrate*, m. 73°, $[\alpha]_D^{25}$ 138° (H_2O, *c* 2.25) after 5 min., changing to 81° in 95 hrs.; liquid NH_3 gives *2,3,4-trimethyl-d-mannonamide*, m. 143°, $[\alpha]_D^{25}$ 5° (H_2O, *c* 0.8). Oxidation of II with HNO_3, esterification and reaction with NH_3 in MeOH give *2,3,4-trimethyl-d-mannosaccharodiamide*, m. 228° (decompn.), $[\alpha]_D^{25}$ −17° (MeOH, *c* 0.46), −14° (H_2O, *c* 1.7). C. J. West

Synthesis of certain oligosaccharide acetates in the mannose series. Delbert D. Reynolds and Wm. Lloyd Evans. *J. Am. Chem. Soc.* **62**, 66–9(1940); cf. *C. A.* **33**, 1438. 6-Trityl-β-*d*-mannose 1,2,3,4-tetraacetate (prepd. in 150-g. yield from 100 g. mannose) (46 g.) with HBr in AcOH gives 19.3 g. of β-*d*-mannose 1,2,3,4-tetraacetate (I), m. 135.5–6.5° (m. ps. cor.). I (16 g.), 26 g. of Ag_2O, 100 g. Drierite (preheated at 240° for 2 hrs.) and 150 cc. EtOH-free $CHCl_3$, stirred 1 hr., with subsequent addn. of 5 g. I and then 26.6 g. acetobromogentiobiose in 100 cc. $CHCl_3$ during 1 hr., give 73.4% of *6-β-gentiobiosido-β-d-mannose hendecaacetate* (II), m. 122–3°, $[\alpha]_D^{25}$ −21.02° ($CHCl_3$, *c* 3.92). Acetobromogentiobiose in $CHCl_3$, added to abs. EtOH, Ag_2O and Drierite in $CHCl_3$, gives 82% of *Et gentiobioside heptaacetate* (III), m. 158–9°, $[\alpha]_D^{25}$ −23.06° ($CHCl_3$, *c* 4.12). Condensation of the α-isomer of I with acetobromoglucose gives 45.5% of 6-β-*d*-glucosido-α-*d*-mannose octaacetate (IV) (cf. *C. A.* **32**, 4531[2]). The sp. rotation of II as calcd. by Hudson's rules is −19.7°; that of III is −21.4°; it is pointed out that the values of the epimeric differences as required by H.'s scheme seem to hold for 6-linked sugars although they do not hold for 4-linked sugars. The difference for α-gentiobiose octaacetate and IV (17,900) agrees very well with that for α-*d*-glucose pentaacetate and α-*d*-mannose pentaacetate (18,200); the difference for II and 6-β-*d*-gentiobioside-β-*d*-glucose hendecaacetate (12,600) agrees in a satisfactory way with that for β-*d*-glucose pentaacetate and β-*d*-mannose pentaacetate (11,300). Since the epimeric difference is twice the rotational value of C atom 2, the farther the glucosido portion is removed from this C atom, the less influence it seems to have on the value of the epimeric difference. C. J. West

Reduction products of *d*-glucoheptulose. Fred L. Humoller, Stanly J. Kuman and Fred H. Snyder. *J. Am. Chem. Soc.* **61**, 3370–4(1939).—Diphenylmethanedimethyldihydrazine is a convenient reagent to sep. mixts. of *d*-glucoheptulose (I) and α-*d*-glucoheptose. When I is reduced with Na-Hg β-*d*-glucoheptitol (IA) and a compd. which Khouvine and Nitzberg (*C. A.* **27**, 1865) have called α-*d*-glucoheptulitol (II) were obtained. Evidence is presented to show that II is not a pure chem. entity but consists of mixed crystals of α-glucoheptitol (III) plus a small amt. of an optically active impurity; this evidence is as follows: From the values obtained in elementary analyses and in mol.-wt. detns. it is not possible to write a formula which is consistent with the chem. behavior of II. When II is heated in 10% H_2SO_4 it gives III. II with Ac_2O gives the *heptaacetate*, m. 115°, of III, and Ph_3CCl with C_5H_5N gives the *ditrityl deriv.*, m. 142–3°, of III. A satd. soln. of III in MeOH is also satd. with respect to II. Soly. values at 37 ± 1° in MeOH (mg. in 10 ml. MeOH) are: IA 48, II 63.5, III 69.9. C. J. W.

Polysaccharides. XXXIII. The methylation of cellulose. W. N. Haworth, E. L. Hirst, L. N. Owen, S. Peat and F. J. Averill. *J. Chem. Soc.* **1939**, 1885–99; cf. *C. A.* **34**, 7254.—The prepn. and methylation of Me_2CO-sol. cellulose acetate have been repeated; the closest adherence to the conditions prescribed in the earlier papers was observed and the conclusions reached previously have been confirmed in all essentials (Haworth, Hirst and Thomas, *C. A.* **25**, 3828). The investigation of Haworth and Machemer (*C. A.* **26**, 5921) has been extended inasmuch as a method has been devised whereby the necessity for the partial deacetylation of cellulose triacetate has been avoided. The method takes advantage of the fact that fully acetylated cellulose, although it is insol. in Me_2CO, nevertheless swells in dioxane or in a mixt. of Me_2CO and dioxane to give a clear, highly viscous soln. which is eminently suitable in regard to phys. state for the subsequent methylation process. A study is also reported of the direct methylation of cellulose, i. e., the methylation of cellulose (either as cotton sliver or cotton linters) without the intermediate formation of a cellulose acetate. In this method use is made of the fact that alkali brings about extensive swelling of the cellulose fibers with a consequent increased facility of penetration of the methylating agents. The cellulose is stirred for some hrs. with a large excess of 30% NaOH until the whole forms a gelatinous mass. Me_2SO_4 in dioxane is then added very slowly during 12 hrs. and the mixt. maintained at the required temp. throughout. The effectiveness of the methylation is to be judged by the fact that after 1 treatment at room temp. a methylated cellulose having 41% MeO is obtained. The conditions of direct methylation were varied in respect to temp. of methylation, no. of treatments with the methylating agent, the nature of the surrounding atm., the methylation being conducted in air or in an inert atm. of N. It appears that the normal methylation of an end group in cellulose which takes place in the presence of air does not occur if the preliminary methylation is carried out in a N atm. Results are given of the methylation of 14 samples of cellulose, all of which were hydrolyzed; the original should be consulted for the mass of exptl. detail. The technique of H. and M. was used for the detn. of the end group in the methylated products, except that the use of cold concd. HCl was abandoned in favor of a hot mixt. of equal vols. of glacial AcOH and 8% HCl as the hydrolyzing agent; by this method the formation of levulinic acid was reduced to a min.; no other acid product was found. **XXXIV. The methylation of cellulose in an inert atmosphere.** W. N. Haworth, R. E. Montonna and S. Peat. *Ibid.* 1899–901.—Cellulose was exhaustively methylated in an atm. from which O was excluded and all subsidiary operations, such as washing and filtration, were carried out as rapidly as possible and in the cold as long as any alkali was in contact with the cellulose. A progressive diminution of particle size of the methylated cellulose as the no. of methylations is multiplied was observed; the results of a chem. assay after 15 such methylations are given. Cryst. tetramethylglucose was identified as 1 of the products of hydrolysis and the proportion of this substance found corresponded to a min. chain length of 700 glucose units for the methylated cellulose. The mol. wt. of the cellulose detd. osmometrically corresponded to 450 units. It is probably more accurate to state that tetramethylglucose was undoubtedly present and the amt. of it isolated corresponded to a min. chain length of 700 glucose units. Actually 134 g. of methylated cellulose yielded 160 mg. of the glucoside. **XXXV. Hydrocellulose.** H. C. Carrington, W. N. Haworth, E. L. Hirst

and M. Stacey. *Ibid.* 1901–4.—Hydrocellulose (I) prepd. by the action of HCl had an I no. of 1.3 and a Cu no. of 3.3; it gave a bright-yellow color with I; it was sol. to the extent of 30% in 15% aq. NaOH. I (20 g.) gives 32 g. of an Ac deriv. with 43.2% Ac, $[\alpha]^{17}_{5770}$ −20° ($CHCl_3$, *c* 1); this material (22 g.) was fractionated by Me_2CO and pptn. with Et_2O and petr. ether into 3 parts (7, 3 and 11 g.) with $[\alpha]^{20}_{5770}$ −19°, −20° and −21.2°, with apparent chain lengths of 77, 63 and 68. The methylated I (84 g.) was fractionally pptd. from $CHCl_3$ by petr. ether (4, 5 and 60 g.) with $[\alpha]^{20}_{5770}$ −5°, −5° and −7° ($CHCl_3$, *c* 0.5) and apparent chain lengths of 44, 59 and 54. End-group assay on the methylated I showed the av. mol. size to correspond to a chain of about 70 glucose units. **XXXVI. Hydrocellulose.** W. N. Haworth, S. Peat and W. J. Wilson. *Ibid.* 1904–8.—A hydrocellulose (I) prepd. by soaking cotton sliver in 5% HCl at room temp. and which retained its fibrous form (Cu no. 2.6) was sepd. mechanically into fiber (II) and powder (III). III contained 5.5% ash and 1.3% moisture and II gave 0.2% ash and 4.5% moisture; the Cu nos. were 5.4 and 1.7. The I contains no acidic HO groups and no uronic acid groups. Each form gave more than 90% of cryst. glucose on acid hydrolysis. End-group assay showed that the I had an av. chain length of 120 glucose units and the II a chain length of 200; the I no. of the III corresponded to a chain length of 70 glucose units. I appears to be a cellulose which has undergone degradation in the sense that hydrolysis of some glucosidic linkages has taken place under the influence of the mineral acid used in its prepn.; it is thus constituted of fragments of the original cellulose chain mols., the essential structure of these fragments being the same as in the parent cellulose; the hydrolytic cleavage has proceeded further in III than in II. When cotton linters are boiled with 0.25 *N* or 2.5 *N* aq. NaOH only 3% is dissolved; 0.25 *N* NaOH dissolves 40% of III and 12% of II; 2.5 *N* NaOH dissolves 60% of III and 12% of II; the soly. in alkali appears to be inversely proportional to the length of the chain of glucose mols. Cellodextrin with a chain length of 12 units was completely dissolved by boiling 0.25 *N* NaOH and a dextrin of 18 units was sol. to the extent of 96% in 0.25 *N* and completely in 2.5 *N* NaOH. **XXXVII. Oxycellulose.** G. L. Godman, W. N. Haworth and S. Peat. *Ibid.* 1908–14.—Oxycellulose (I), prepd. by oxidation of cotton linters in cold acid by 0.25 *N* $KMnO_4$, retained the fibrous structure of the cellulose but had a Cu no. of 14 and was sol. to the extent of 50% in boiling 1% NaOH. I also contained 1.5% CO_2H groups. On boiling I with 0.25 *N* NaOH 50% is dissolved; extn. with 2.5 *N* NaOH dissolves 50% of the remainder (25% of the original I). I is not readily acetylated by methods which are appropriate for cellulose itself. The material insol. in 0.25 *N* NaOH did not possess the properties peculiar to I; its reducing power (Cu no.) was 0.27 and uronic acid residues were absent; it was no longer resistant to the usual acetylation process and was easily methylated by treatment of the acetate with Me_2SO_4 and 30% NaOH. The methylated deriv. (MeO 44.6%) was sepd. by pptn. from $CHCl_3$ with light petr. ether into 3 fractions which showed viscosities in *m*-cresol soln. corresponding to apparent chain lengths of 110, 92 and 55 glucose units. An assay of the chain length by the end-group method gave a value of 90 glucose units. It is considered that the material insol. in weak alkali is constituted of chain-mols. of glucose units united as in the original cellulose mol. and the av. length of these chains corresponds to 90 glucose units. The fraction of I sol. in 2.5 *N* NaOH had a Cu no. of 0.23 and underwent acetylation and methylation with the usual reagents; the Me deriv. was constituted of chain-mols. of approx. uniform size; the chain length, detd. by the end-group method, was 35 glucose units. It is apparent that the shorter-chain cellodextrin is produced by the fragmentation, under the influence of 2.5 *N* alkali, of the longer-chain mols. of the 0.25 *N* NaOH-insol. fraction. Profound and extensive decompn. has occurred in the fraction sol. in 0.25 *N* NaOH; the same decompn. occurs on treatment of I with 3% $Ba(OH)_2$; the products isolated include HCO_2H, AcOH, lactic acid, a dihydroxybutyric acid, whose *di-Me ether* has n^{20}_D 1.4402 (*Me ester*, n^{20}_D 1.4230), an acid $C_5H_7(OH)_4CO_2H$, whose tetra-Me ether has n^{20}_D 1.4560, $[\alpha]_D$ −4.8°, and a γ-lactone has n^{20}_D 1.4496, $[\alpha]^{20}_D$ 64.4°; the corresponding *acid*, $C_5H_7O_3(OMe)_3$, has $[\alpha]_D$ −7.5°, changing to 32.4° in 25 hrs. Cold acid hydrolysis of 10 g. of I (72% H_2SO_4 for 14 days at room temp.) gives 1.42 g. of a Ba salt of an aldobionic acid, $[\alpha]_D$ 61.7°. Acid hydrolysis of I (72% H_2SO_4 for 7 days at room temp., diln. with a large amt. of H_2O and boiling 16 hrs.) gives 81.2% of glucose; the 0.25 *N* alkali-insol. portion of I gives 89.7% of glucose. The 2.5 *N* NaOH-insol. portion has an apparent chain length of 60 glucose units. The results show that the fragmentation of the cellulose chain which normally occurs under the action of alkali is greatly accelerated if the cellulose is first treated with an acid oxidizing agent. The latter effects the conversion of a portion (6.5% in this case) of the terminal primary alc. groups of the glucose units into CO_2H groups. The high reducing power of I suggests that the fragmentation of the cellulose chain occurs during the oxidation with the formation to the extent of 50% of very short chains of glucose units (the max. chain length would seem to be 30–5 glucose units); the short-chain mols. dissolve in weak alkali and undergo degradation of the kind suffered by the reducing sugars under the same conditions. **XXXVIII. The constitution of glycogen from fish liver and fish muscle.** W. N. Haworth, E. L. Hirst and F. Smith. *Ibid.* 1914–22.—Glycogens from fish liver (dogfish, haddock and hake) and fish muscle (dogfish) have been examd. All of the methylated glycogens gave on hydrolysis an amt. of tetramethylglucose (av. 9.3%) which corresponds to a chain length of 12 glucose residues for the repeating unit. The amt. of dimethylmethylglucoside formed in the hydrolysis is never less than that of the tetramethylmethylglucoside; any formula proposed for the structure of glycogen must take account of the occurrence of dimethylglucose. Some of the samples of glycogen apparently reverted to an insol. form on standing 4 months; they were rendered sol. in cold H_2O by soln. in cold dil. AcOH or better in cold dil. mineral acid and pptn. with EtOH. C. J. West

Rates of reaction of cyclopropyl ketimines with water. John B. Cloke. *J. Am. Chem. Soc.* **62**, 117–19(1940); cf. *C. A.* **23**, 2438.—Details are given of the prepn. of Et (I) and Ph cyclopropyl ketimmonium chloride (II). The rate of hydrolysis at 0° was followed by transferring portions to alkali and extg. with CCl_4 the liberated base which is titrated with acid. Values for II of *k* min.$^{-1}$ for 0.05 and 0.1 *M* solns are 0.0249 and 0.0231 (computed graphically) or 0.0252 and 0.0243 (computed arithmetically). I is much more sol. in H_2O and is far more reactive with H_2O than is II; the value of *k* (graphic) is about 0.036 (approx. because of the very rapid extn. procedure used which was demanded by the great reactivity of the liberated base). The free base from I gives a value of *k* of about 0.5 (half-time value of about 1.5 min. for the base in H_2O at 0°); the value for the base from II ($k \times 10^3$ min.$^{-1}$) shows a drift from 10.1 to 7.3 (11.3 to 6.4) in a reaction mixt. which was not strictly homogeneous, probably caused by the reversing action of the NH_3. The value of *k* min.$^{-1}$ at 0° decreases as the H-ion concn. rises: I with 0.05 and 0.2 *N* HCl at 0°, 0.00284 and 0.00118; II with 0.01, 0.05 and 0.2 *N* HCl at 0°, 0.00747, 0.00435, 0.00189. That the free base from I is more reactive with H_2O than its HCl salt suggests that the dissolved salt may exist largely in the form of an enammonium tautomer. C. J. West

Allenes. II. The preparation of 1-cyclohexyl-2,3-pentadiene. Fred Acree, Jr., and F. B. LaForge. *J. Org. Chem.* **5**, 48–53(1940); cf. *C. A.* **34**, 7317.—In continuation of their studies of the structure of the 5-membered side-chain of pyrethrolene, *1-cyclohexyl-2,3-pentadiene* (I) is prepd. $MeCH{:}CClCHO$ (35 g.) in 200 cc. Et_2O is allowed to react with a Grignard reagent prepd. from 84 g. $C_6H_{11}I$ and 10 g. Mg in 300 cc. Et_2O and decompd. with NH_4Cl. *1-Cyclohexyl-2-hydroxy-3-chloro-3-pentene* (II) (30 g.), b_9 130–5°, m. 39–40°, n^{25}_D 1.4893, is obtained. Hydrogenation of II with Pd-$CaCO_3$ gives *1-cyclohexyl-2-pentanol* (III), b_9 112–14°, n^{25}_D 1.4620. Action of 6 g. PCl_5 on 5.2

g. II in 25 cc. cold petr. ether, boiling the mixt. for a few mins. on a water bath and washing the soln. with ice H_2O, dil. $NaHCO_3$ and H_2O give on distn. 4.2 g. *1-cyclohexyl-2,3-dichloro-3-pentene* (IV), b_{11} 131–3°, n_D^{25} 1.4965. When 10 g. IV in 25 cc. EtOH is dropped into a boiling suspension of 25 g. Zn in 25 cc. EtOH with stirring and the mixt. is boiled for 15 min., filtered and dild. with H_2O, an oil seps. which is extd. with Et_2O. The Et_2O soln. is washed with Na_2CO_3 soln., dried, distd. and gives 4.6 g. I, b_{12} 82–5°, n_D^{25} 1.481. I does not react with maleic anhydride. Its structure is proved by hydrogenation to amylcyclohexane, b. 200 5°, n_D^{15} 1.4474, and by ozonization whereby AcH, cyclohexylacetaldehyde (identified as its semicarbazone, m. 157–9°), and cyclohexylacetic acid (V) are formed. Oxidation of I with $KMnO_4$ yields AcOH and V. An attempt to apply the general series of reactions previously used for 1-phenyl-1,2-butadiene for the prepn. of I failed because $C_6H_{11}MgI$ reduces 2,2,3-trichlorobutanol to the butanol. F. E. Brauns

Physical properties and chemical constitution. IV. Methylcyclohexane and the multiplanar structure of the methylcyclohexane ring. David M. Cowan, George H. Jeffery and Arthur I. Vogel. *J. Chem. Soc.* **1939**, 1862–5; cf. *C. A.* **33**, 1458, 8180³.—Further exptl. work has shown that the methylcyclohexanes *A* (part III) are in fact slightly impure forms of *B'*, for their phys. properties changed appreciably during 6-months' keeping and redistn. over Na afforded material having properties agreeing closely with those originally recorded for *B'*; the properties of *B'* remained unchanged after keeping 1 yr. The view that *A* was a stable form of methylcyclohexane being no longer tenable, expts. were directed to obtain evidence for the existence of forms *B* and *B'*. Clemmensen reduction of pure 2-, 3- and 4-methylcyclohexanones (I), followed by catalytic reduction (to reduce methylcyclohexenes present) gives a product whose phys. properties agreed closely with those originally found for *B'*; this establishes the existence of the *B'* form but no evidence could be found for the *B* modification. The reduction of the semicarbazones of the 2- and 4-I with EtONa gives the *B*-form, which passed in several days into the *B'*-form; 3-I yielded apparently anomalous results; they do not exclude the possibility of the presence of varying quantities of another isomer. The expts. with 2- and 4-I seem to establish the existence of 2 forms of methylcyclohexane, 1 of which (*B*) is comparatively unstable and passes easily into a stable form (*B'*) and thus provides direct evidence for the existence of the methylcyclohexane ring in multiplanar form. The *B* form is particularly sensitive to chem. reagents; e. g., of some 18 prepns. from the semicarbazones it was possible to prep. the *B* form 6 times, the *B'* form being obtained in every other case; if a rubber stopper is used, the *B'* form is invariably obtained. Phys. data are given for many prepns. C. J. West

Pinacolone rearrangement of 1,2-dimethylcyclohexane-1,2-diol and 1,2-dimethylcyclopentane-1,2-diol. Hans Meerwein. *Ann.* **542**, 123–9(1939).—*cis*-1,2-Dimethylcyclohexane-1,2-diol, heated 3 hrs. at 150–60° with 25 cc. of 2% H_2SO_4, gives 70% of 1,1-methylacetylcyclopentane, b_{11} 50.2–50.9°, d_4^{20} 0.9083, n_D^{20} 1.44448. Bartlett and Bavley (*C. A.* **33**, 1471) obtained 87% of 2,2-dimethylcyclopentanone by heating *cis*-1,2-dimethylcyclopentane-1,2-diol with 30% H_2SO_4 but the trans isomer (II) gave only a nonvolatile brown resin. Repetition of this work showed that II with 30% H_2SO_4 gave only 7% of I but when 6 g. of II is added gradually to 42 g. concd. H_2SO_4 at −10° 22% of I results. The difference in the behavior of the 2 isomers is thus one of degree and not of kind. C. J. West

Structure of vinyl polymers. VIII. Polystyrene and some of its derivatives. C. S. Marvel and Neil S. Moon. *J. Am. Chem. Soc.* **62**, 45–9(1940); cf. *C. A.* **34**, 9787.—*o*-BrC_6H_4CHO and MeMgCl in Et_2O give 87% of *o-bromophenylmethylcarbinol* (I), $b_{6.5}$ 108.5°, d_{27}^{27} 1.470, n_D^{25} 1.5702; MeMgI gives a red product from which the I could not be removed completely. Heating 30 g. I with 5 g. $KHSO_4$ and 0.3 g. $C_6H_4O_2$ (II) at 155–60° and 21–30 mm. gives 33% of *o-bromostyrene* (III), b_4 65°, d_{27}^{27} 1.468, n_D^{25} 1.5893. I and $SOCl_2$ give 83% of *o-bromo-α-chloroethylbenzene*, b_2 63–5°, d_{20}^{20} 1.499, n_D^{20} 1.5693; it did not lose HCl on treatment with quinoline. III contg. 1–2% II polymerizes slowly and a solid product was obtained only after several months. III is polymerized in 3–5 min. at 175° or in several hrs. at 160°; with 0.2% Bz_2O_2 at 140–50° polymerization is complete in a few min. The *polymer* (IV) is a hard, brittle, transparent mass, which develops an amber color in a few months; pptn. from C_6H_6 or dioxane by pouring into a large excess of Et_2O or MeOH gives an amorphous powder, having n_D^{25} 1.6333 ± 0.003 for an approx. mol. wt. of 24,000. The *polymer* of the *m*-isomer of III (*n* 1.68) and that (V) of the *p*-isomer (*n* 1.62) are similarly prepd. Refluxing 1 g. of IV with 5 g. activated Zn in 500 cc. dioxane for 7 days gives a buff compd. with 35.4% Br (III has 43.7%). Cu bronze in $PhNO_2$ gives a black tar. Boiling 5 g. IV with excess Na in 2:1 C_6H_6 for 50 hrs. gives a product with about 37% Br; after 3 days in PhMe it contains 35% Br; complete removal follows 300–400 hrs. in boiling xylene. The last reaction gives a white or gray porous brittle mass; it appears that the Br is replaced by Na without a cyclization reaction. Reaction of the xylene soln. with CO_2 gives an acidic material but no definite products could be isolated. The debrominated polymer could not be oxidized to characteristic products and heating with Se at 400° for 20 hrs. gives brown gums. Refluxing V with Na in xylene for 550 hrs. removes 99% of the Br. This indicates a 1,3-structure for IV and V. α-Chlorostyrene and BF_3-AcOEt in EtOH slowly give 1,3,5-$C_6H_3Ph_3$; definite polymeric products could not be obtained. Styrene bromohydrin and AcCl (refluxed 10 hrs.) give 91% of *α-acetoxy-β-bromoethylbenzene*, b_3 105 7°, d_{20}^{20} 1.386, n_D^{20} 1.5380; quinoline and a little II give 34% of *α-acetoxystyrene*, $b_{3.5}$ 87.5–9.5°, d_{20}^{20} 1.074, n_D^{20} 1.5533; *dibromide*, m. 93.5–4.5°. True polymers could not be prepd. from α- and β-acetoxystyrene, β-bromostyrene or α-methoxystyrene. C. J. West

Amines related to 2,5-dimethoxyphenethylamine. I. Richard Baltzly and Johannes S. Buck. *J. Am. Chem. Soc.* **62**, 161–4(1940).—2,5-$(MeO)_2C_6H_3CH_2CH_2NH_2$ (I) yields a *HCl salt*, m. 139° (all m. ps. cor.). I (9 g.), 40 cc. 36% HCHO and 0.1 cc. HCO_2H, heated 3 hrs. at 125°, give *2,5-dimethoxyphenethyldimethylamine*, b_{23} 159°; *HCl salt*, m. 148°, rather hygroscopic; the methiodide in H_2O and AgCl give *2,5-dimethoxyphenethyltrimethylammonium chloride*, m. 184–5°, very hygroscopic. 2,5-$(MeO)_2C_6H_3Ac$ and $BrCH_2CO_2Et$, condensed by use of Zn-Cu alloy, the ester dehydrated by $POCl_3$ and sapond., give *2,5-dimethoxy-β-methylcinnamic acid*, m. 113.5°; catalytic reduction and sapon. of the ester give *β-(2,5-dimethoxyphenyl)butyric acid*, m. 79°; heating in a stream of NH_3 at 220–30° for 2 hrs. gives the *amide*, m. 121°; the Hofmann reaction with NaOCl gives 45% of *β-(2,5-dimethoxyphenyl)propylamine*, b_1 114°; *HCl salt*, m. 149–50°; Decker's method (D. and Becker, *C. A.* **7**, 1513) gives *β-(2,5-dimethoxyphenyl)propylmethylamine*, whose *HI salt* m. 131° and *HCl salt*, m. 146°; the corresponding *dimethylamine* forms a *HCl salt*, m. 182–3°; the *trimethylammonium chloride* m. 159–61° (monohydrate, m. 92°); the *iodide* m. 139°. $CH_2(CO_2Et)_2$ and 2,5-$(MeO)_2C_6H_3CHO$ with piperidine give di-Et 2,5-dimethoxybenzalmalonate, m. 183° (decompn.), catalytically reduced to *di-Et 2,5-dimethoxybenzylmalonate*, m. 156.5° (decompn.); reaction with MeI and EtONa and sapon. give *2,5-dimethoxybenzylmethylmalonic acid*, m. 143° (decompn.); heating above 150° gives *α-methyl-2,5-dimethoxyhydrocinnamic acid*, cream, m. 59.5°; *amide* (II), m. 99° (by heating acid in stream of NH_3 at 220–30° for 2 hrs.; the same amide results from 2,5-$(MeO)_2C_6H_3CHO$ and $MeCHBrCO_2Et$ with Zn, dehydrating with $POCl_3$, catalytic reduction, sapon. and reaction with NH_3); the dehydration with $POCl_3$ or the subsequent distn. results in extensive polymerization, the yield of unsatd. ester being about 20%. Hofmann reaction with II (addn. of II in dioxane to the NaOCl soln.) gives 70% of *β-(2,5-dimethoxyphenyl)isopropylamine*, b_2 137–40°; *HCl salt*, m. 117.5°; *HI salt*, m. 138°; this also results in poor yield

by catalytic reduction of 2,5-dimethoxynitropropenylbenzene (Kauffmann, *C. A.* **11**, 2794); Decker's method gives the corresponding *methylamine*, whose *HCl salt* m. 98.5°; the *dimethylamine*, $b_{0.5}$ 118–21°, forms a *HCl salt*, m. 138–9°; the *trimethylammonium chloride*, m. 203°, very hygroscopic; the *iodide*, m. 142°. **II.** *Ibid.* 164–7. —2,5-$(MeO)_2C_6H_3CHO$ and $BrCH_2CO_2Et$, condensed by the Reformatskiĭ method, give 80% of Et β-(2,5-dimethoxyphenyl)hydracrylate, yellow, b_1 164–7°; the *hydrazide*, m. 161.5° (all m. ps. cor.); the Curtius rearrangement yields *5-(2,5-dimethoxyphenyl)-2-oxazolidone*, m. 107°, cleavage of which by cold, concd. HCl gives *β-(2,5-dimethoxyphenyl)-β-hydroxyethylamine-HCl*, m. 158.5°; this and the other salts may be crystd. from abs. EtOH by addn. of Et_2O or AcOEt or both; the amine also results by reduction of *2,5-dimethoxyphenacylamine-HBr*, yellow, m. 195° (decompn.), which is prepd. by condensation of 2,5-$(MeO)_2C_6H_3COCH_2Br$ (I) and hexamethylenetetramine and hydrolysis with HBr. I and $PhCH_2NHMe$ in Et_2O give *2,5-dimethoxyphenacylmethylbenzylamine* (II), whose *HCl salt*, m. 167.5°; reduction with PtO_2 and H in EtOH gives *β-(2,5-dimethoxyphenyl)-β-hydroxyethylmethylamine-HCl*, m. 151.5°. II with MeMgI, followed by catalytic reduction, yields *β-(2,5-dimethoxyphenyl)-β-hydroxypropylmethylamine*, whose *HCl salt* m. 158–9°. 2,5-$(MeO)_2C_6H_3Ac$ and $BrCH_2CO_2Et$, condensed with Zn-Cu alloy, yield after sapon. *β-methyl-β-(2,5-dimethoxyphenyl)hydracrylic acid*, m. 121–2°; the *hydrazide*, m. 112°, results in 27% yield from the crude washed (but not distd.) ester; unsatisfactory results were obtained with the distd. ester or that prepd. from the acid, due to the tendency of the compds. to dehydrate when distd. or subjected to acids; Curtius rearrangement yields *5-methyl-5-(2,5-dimethoxyphenyl)-2-oxazolidone*, m. 159°; cold concd. HCl gives *β-(2,5-dimethoxyphenyl)-β-hydroxypropylamine-HCl*, m. 174°. Bromohydroquinone di-Me ether, converted into the Grignard reagent and reacted with Me_2NCH_2CN, the base liberated with NH_3, extd. with Et_2O and treated with EtOH-HCl, gives *2,5-dimethoxyphenacyldimethylamine-HCl* (III), m. 171° (decompn.), catalytic reduction of which yields *β-(2,5-dimethoxyphenyl)-β-hydroxyethyldimethylamine-HCl*, m. 155°; its *methochloride*, m. 185 6°. The free base from III and MeMgI give *β-(2,5-dimethoxyphenyl)-β-hydroxypropyldimethylamine-HCl*, m. 176.5°; *methochloride*, m. 213.5°. *α-Isonitroso-2,5-dimethoxypropiophenone*, pale yellow, m. 97–8°, was prepd. by Hartung's method (U. S. pat. 1,989,093, *C. A.* **29**, 1941[7]); catalytic reduction yields *β-(2,5-dimethoxyphenyl)-β-hydroxyisopropylamine-HCl*, m. 175 6° (decompn.). The α-Br deriv. of 2,5-$(MeO)_2C_6H_3COEt$ with excess of $MeNH_2$ in Et_2O gives *2,5-dimethoxy-α-methylaminopropiophenone* (IV), whose *HCl salt*, m. 172–3° (decompn.); catalytic reduction yields *β-(2,5-dimethoxyphenyl)-β-hydroxyisopropylmethylamine*, whose *HCl salt* (V) m. 170°. The *α-dimethylamino analog* of IV m. 154 6° (decompn.); *that* of V m. 198° (decompn.); the methochloride of the latter m. 221–3° (decompn.). It is assumed that the hydroxyisopropylamine group has the ephedrine, rather than the ψ-ephedrine, configuration; the relatively high m. ps. and the methods of prepn. support this view. C. J. West

Sympathicomimetics. Preparation of nitrogen-substituted β-phenylisopropylamines. Armando Novelli. *Anales asoc. quím. argentina* **27**, 169–71 (1939).—A series of *N*-alkyl derivs., $PhCH_2CHMeNRR'$ (R,R' = H or alkyl), were prepd. to det. the effect of the alkyl radicals joined to N on the pharmacol. action. $PhCH_2COMe$ was prepd. by the method of Julian and Oliver (*C. A.* **32**, 8387[4]). The amines were obtained as the HCl salts directly and purified by soln. in abs. alc. and pptn. by anhyd. ether. The yields were from 50–70%. The following *α-phenyl-β-alkylaminopropane hydrochlorides* are described: Me, m. 133-5°; Et, m. 145–6°; Bu, m. 168–9°; Am, m. 186–7°; di-Me, m. 156–8°; di-Et, m. 160–1°; piperidyl, m. 206–8°; all temps. uncor. E. M. Symmes

The reactions of arylacetoaminopolymethines. Terutar Ogata. *Proc. Imp. Acad.* (Tokyo) **13**, 325–7 (1937) (in German); cf. *C. A.* **28**, 5816[1].—The arylacetamino compds. (I) react readily with compds. having an active Me group (II) in the presence of acid-combining substances.

$$(C_nH_n\ldots)(CH{:}CH)_2NC_6H_5 + CH_3(C_nH_n\ldots) = (C_nH_n\ldots)\text{-}RNX\ (I)\ COCH_3\ RNX\ (II)\ RNX$$

$$(CH{:}CH)_2CH{:}(C_nH_n\ldots) + HX + CH_3CONHC_6H_5$$

Amines may be identified by the highly colored aminocyanines, which they form with I. I reacts with malonic, alkylmalonic and glutaconic acids in the presence of trialkylamines to form polymethine cyanines, *meso*-alkylpentamethine cyanines and heptamethine cyanines, resp. A yield of 0.18 g. V (R = Me), needles, m. 217°, was obtained by heating 0.87 g. III, 0.12 g. IV (R = Me) and 0.6 cc. Et_3N for 20 min. at 80°, washing with Et_2O and then H_2O, and recrystg. twice from alc. $2EtIN.C_6H_4.O.C{:}CHNAcPh$ (III) + $RCH(CO_2H)_2$ (IV) → $2EtIN.C_6H_4.O.C{:}CHCR\ CHCH.O.C_6H_4.NEt$ (V) + $2CO_2$ + $2CH_3CONHC_6H_5$ + HI. By the same procedure 0.03 g. V (R = Et), gray-blue crystals, m. 220°, was prepd. from 0.87 g. III, 0.13 g. IV (R = Et) and 0.6 cc. Et_3N. The sensitizing max. were at 610 μμ for V (R = Me) and 615 μμ for V (R = Et). Ruth Berggren

Secondary amines from nitro compounds. Wm. S. Emerson and H. W. Mohrman. *J. Am. Chem. Soc.* **62**, 69–70 (1940).—Reduction was carried out with 0.1 mole NO_2 compd., 0.3 mole aldehyde and 2 g. AcONa in 150 cc. EtOH with 3 6 g. Raney Ni at an initial pressure of 40 lbs.; shaking was continued for 12–24 hrs., 0.42–0.62 mole of H being taken up. The following yields were obtained: PhNHMe 50%; PhNHEt 57, 63; PhNHBu 94, 96; PhNHAm 84; *N*-heptylaniline 40; $PhNHCH_2Ph$ 33; *N*-butyl-*p*-anisidine 31 (*p-bromobenzenesulfonamide*, m. 72–3°); *N*-butyl-α-naphthylamine 60 (*p-chlorobenzamide*, m. 242 3°); *N-amyl-α-naphthylamine*, b_4 136–46°, d_{20}^{20} 1.102, n_D^{20} 1.6460, 43% (*p-bromobenzamide*, m. 226–7°); *N*-butyl-*p*-toluidine 40, 85; *N-heptyl-p-toluidine*, b_4 135–50°, d_{20}^{20} 0.906, n_D^{20} 1.5055 (*p-bromobenzenesulfonamide*, m. 52–2.5°); *N,N*-dibutyl-*p*-toluidine, b. 295 6°, d_{20}^{20} 0.976, n_D^{20} 1.5514, 53% (*picrate*, m. 186 7°); *N,N-diheptyl-p-tdluidine*, $b_{2.5}$ 175–200°, d_{20}^{20} 0.943, n_D^{20} 1.5089, 34% (*HCl salt*, m. 136°). C. J. West

Molecular dissymmetry due to symmetrically placed hydrogen and deuterium. The α-pentadeuteriophenylbenzylamine problem. G. R. Clemo and G. A. Swan. *J. Chem. Soc.* **1939**, 1960 1; cf. *C. A.* **30**, 5950[6].—Since Adams and Tarbell (*C. A.* **32**, 4961[1]) failed to resolve α-pentadeuteriophenylbenzylamine (I), the previous work has been repeated. The C_6D_5 used m. 5.5°; the C_6D_5Bz m. 47° (oxime, m. 142°); the I b_1 135–40°; I *l-l tartrate*, m. 179–80°; crystn. 10 times from EtOH-light petr. causes no change in m. p. or $[\alpha]_D^{18}$ 12.4° (EtOH, *c* 1.120); the recovered I has no optical activity; the oxalate m. 204–5° and is also optically inactive. C. J. West

The reaction of alloxan with aromatic amines. Alloxan derivatives of *N,N*-dimethyl-*o*-diaminobenzenes. Hermann Rudy and K. E. Cramer. *Österr. Chem.-Ztg.* **42**, 329–36 (1939); cf. *C. A.* **33**, 4986[6].—*o*-$H_2NC_6H_4NMe_2$ and its homologs react with alloxan in different ways depending on conditions. Thus, the anil, *alloxan 5-(2-dimethylaminoanil)* (I), m. 248°, is formed in the absence of a condensing agent. The *p*-H atom to the NMe_2 group is so reactive that in addn. to the formation of I, a phenyldialuric acid likewise is formed. With excess of alloxan in the presence of HCl no anil deriv. is formed, but instead a substituted dialuric acid, *5-(3-barbiturylideneamino-4-dimethylaminophenyl)dialuric acid* (II), m. 265°, is obtained. Simple dialuric acids with an unsubstituted NH_2 group could not be isolated when a 1:1 mol. ratio of the amine and alloxan was employed. In a similar manner 4,3-$H_2N(Me_2N)C_6H_3Me$ reacts with alloxan, yielding the

corresponding anil, *2-dimethylamino-4-methylbarbituryli-deneaniline* (III), m. 248°, and with excess alloxan *5-[3-(barbiturylideneamino) - 4 - dimethylamino - 6 - methylphenyl]dialuric acid* (IV), m. 235–40°. From 3,4-H_2N-(Me_2N)C_6H_3Me and 1 mol. alloxan hydrate the anil, *2-dimethylamino-5-methylbarbiturylideneaniline* (V), m. 248°, is obtained and with excess alloxan, *5-[4-(barbiturylideneamino) - 5 - dimethylamino - 2 - methylphenyl]dialuric acid* (VI), m. 255–60°. The formation of II, IV and VI indicates a reactive nuclear H atom para to the NMe_2 group and another para to the alloxanimino fragment. The *o*-H atoms to the amino groups are unreactive in the formation of phenyldialuric acids. Thus, with 1,2-dimethyl-4-amino-5-dimethylaminobenzene and 1 mol. alloxan hydrate, only the anil, *2-dimethylamino-4,5-dimethylbarbiturylideneaniline* (VII), m. 248°, is obtained. It is noted, however, that besides the barbiturylideneaminophenyldialuric acids which form in these reactions other compds. which are oxidation products of the anils arise in more or less appreciable quantities and these are considered later in this article. The barbiturylideneaminophenyldialuric acids are a new type of alloxan deriv. These no doubt were the type of compds. that Kühling (*Ber.* 26, 543(1893)) mistakenly described as dialloxallyl-*o*-aminoditolylamines. The chem. properties of homologs of I are as follows: well-crystd. yellow compds. insol. in H_2O, EtOH, Et_2O, C_6H_6, sol. in AcOH and especially in hot C_5H_5N, also sol. in both alk. and acid solns. and can be recovered unchanged from such solns. after short exposure. The m. ps. reported are indefinite and less characteristic and refer to rapid heating conditions. For purposes of identification the reaction with CH_2N_2 was employed wherein the corresponding di-Me compds. were obtained. The latter derivs. gave sharp m. ps. as follows (R = dimethylalloxan residue): 2-$Me_2NC_6H_4N$:R, 186°; 2,4-$Me_2NMeC_6H_3N$:R, 175°; 5,2-Me(Me_2N)C_6H_3N:R, 174°; 4,5,2-Me_2(Me_2N)C_6H_2N:R, 175°. The stability of the alloxan 2-aminoanils was reaffirmed by that of the 2-dimethylaminoanils. Thus no cleavage into amine and alloxan was observed even after continued heating with dil. or concd. HCl in sealed tubes. There was some evidence of transformation of these products in which the alloxan fragment still remained linked to the original N atom and these will be described below. Na_2CO_3 and alk. solns. hydrolyze and degrade I and its homologs when heated. Alkali decomps. I into NH_3, CO_2 and *2-dimethylaminophenyliminomalonimide* (VIII), m. 239°. Similarly VII yielded *(2-dimethylamino-4,5-dimethylphenylimino)-malonimide* (IX), m. 250°. The structures of VIII and IX are not final although both yield mono-Me derivs. when treated with CH_2N_2, and both are sol. in alkali. However it is admitted that the tendency for the formation of a 4-membered ring is rare. An important fact in support of these structures is the violet color that results when both VIII and IX are treated with HCl-H_2O_2 and this, according to R. and C., is a specific color reaction for the Me_2N group with a free *p*-position and an *o*-orientated C:N— group. I and its homologs are stronger reducing agents than those of similar type already described in the literature. They reduce neutral $AgNO_3$ soln. rapidly at room temp. II and its homologs like the anils are more or less faintly yellow, well-crystd. compds. which decomp. when heated above 235°. They are amphoteric and dissolve unchanged in acids or alkalies. On continued contact with either soln. and when heated they are transformed in some unknown manner. The faintly acidic =NH groups can be methylated with CH_2N_2 with the formation of an alkali-insol. well-crystd. tetra-Me compd. Homologs of I and II react oppositely in their behavior toward $AgNO_3$. With HCl-H_2O_2 II and its homologs produce no violet color, which is in agreement with the fact that there is no available H atom in the *p*-position to the NMe_2 group. The reactions typical for the parent dialuric acids or for alloxantin, with $Ba(OH)_2$, NH_3 or $FeCl_3$-NH_3 and the murexide test are neg. for II and its homologs. The latter type compds. also exist in several mutually convertible forms which are differentiated by their m. p., soly., and H_2O of crystn. content. Thus there are 2 colorless forms of II sol. in MeOH, the one contg. 3, the other 4 mols. of H_2O of crystn. The trihydrate loses 2 mols. H_2O at 100° and 1 mm. while at 135° and 1 mm. it changes slowly into the anhyd. form. The tetrahydrate changes entirely to the anhyd. deep yellow form which m. 235–40° (decompn.). On exposure to air, the anhyd. form changes back to the tetrahydrate with rapid loss of color. Both MeOH-sol. forms become difficultly sol. in glacial AcOH on heating; on standing in a desiccator this transformation is reversed. Several possible explanations are advanced for these changes: first, a reversible hydrolytic cleavage of one alloxan fragment. This has been established to be true for anils previously described in the literature. Furthermore, a temporary addn. of H_2O may occur at the C:N— linkage or there may be a cis-trans isomerization. The strong reducing power of I is one of the most remarkable properties of this class of substances although no action is observed with atm. O_2. With H_2O_2, reaction is rapid and stable end-products consisting of substituted benzimidazolcs are isolated. In neutral or in AcOH soln. I, in the absence of air, dissolves completely. On introducing O and heating, no reducing action is noted and instead a weakly-basic compd. is formed, which forms a picrate, as well as double salts with $ZnCl_2$ and $HgCl_2$. This isolated oxidation product is insensitive to O but is degraded to 1-methylbenzimidazole by H_2O_2. The mechanism of the oxidation is as follows: H_2O adds on at the C:N- bond, producing a strong reducing agent, aminodialuric acid. This through addn. of O and elimination of H_2O is converted into dialuric acid. Finally the latter compd. through elimination of H_2O yields a *bis[5-(1-methyl-2,3-dihydro-3-benzimidoazolyl)-5-barbituryl] ether* (X), m. 365° (decompn.). The structure of X is based upon its elementary analysis, its reactivity to form metal salt double salt compds. and its smooth conversion into 1-methylbenzimidazole. X is oxidized to the latter compd. by heating with H_2O_2-AcOH and to all appearances, 1-methyldihydrobenzimidazolecarboxylic acid is an intermediate product. Similarly the conversion of VII into its corresponding *bisbarbituryl ether* (XI), m. 348°, occurs even more readily. The sensitiveness of this transformation is so marked that it takes place on recrystn. from AcOH. Its stability depends on the nuclear substituents. 1,2-Dimethyl-4-dipropylamino-5-aminobenzene and alloxan yield exclusively the corresponding *bisbarbituryl ether* by virtue of the easy conversion of its anil into the latter. Thus R. and C. have outlined a new method of prepn. of imidazole derivs. In most instances where a NMe grouping appears in such derivs. they have been prepd. through a condensation reaction involving an *o*-substituted -N:O group. X and XI arise in considerable quantity as secondary products in the synthesis of anils from amines and alloxan and can be prepd. readily in this manner inasmuch as they are difficultly sol. in anhyd. C_5H_5N in contrast to the remaining reaction products. Alloxan is the oxidant since it is converted into dialuric acid. I and its homologs in dil. Na_2CO_3 with H_2O_2-AcOH yield red cryst. compds. whose compn. differs from that of the corresponding anils by 1 less CO group. This reaction corresponds with the oxidation of alloxan to parabanic acid. The mechanism consists first in the addn. of H_2O to the anil, opening up the alloxan ring between N(1) and C(6), followed by an alk. cleavage to a hydantoin deriv. which by decarboxylation and oxidation yields the parabanic acid deriv. Thus, from I, *parabanic acid 4-(2-dimethylaminoanil)* (XII), m. 215°, is formed. The conclusion that these red oxidation products of alloxan anils are parabanic acid anils is supported on the one hand by analogy with alloxan degradation to parabanic acid and on the other hand by the violet color with HCl-H_2O_2; furthermore these oxidation products exhibit a pos. violet color where the *p*-H atom to the NMe_2 group is unsubstituted. This color reaction is also specific for the NMe_2 group in the other position to the C:N- linkage. Attempts to establish the structures of these red oxidation products of I and its homologs through clear-cut degradations or by synthetic means have been without success even until the present work. The parabanic acid anils are sensitive to both acids and alkalies. The hydrolytic

products resulting on heating with alkali are strong reducing agents and are rapidly oxidized in air. Energetic oxidation with H_2O_2 in AcOH at higher temps. also yields 1-methylbenzimidazole. It is possible that ring closure is brought about by atm. O although no intermediates have been prepd. The mechanism of the condensation of alloxan with *N,N*-dimethyl-*o*-diaminobenzenes to form the bisbarbituryl ethers is as follows: The reactants in a 1:1 mol. ratio yield the anil. This with another mol. of alloxan or the original reactants in a 1:2 mol. ratio of the amine and alloxan yields the corresponding barbiturylideneamino-substituted phenyldialuric acid. Oxidation of the latter with alloxan after addn. of water results in the formation of the desired bisbarbituryl ether. All three products, the anil, the barbiturylideneamino-substituted phenyldialuric acid and the corresponding bisbarbituryl ether are formed together when the condensation of the reactants occurs in alc. If the mol. ratio of reactants is 1:1 the ether is obtained only in traces. If the mono-HCl salt of the arylamine is reacted with excess alloxan, no anil is isolated, but instead only the other 2 products mentioned. The same observations apply likewise to the dimethylaminotoluidines similarly employed. With 1,2-dimethyl-4-amino-5-dimethylaminobenzene the exception to the rule is observed in that no barbiturylideneaminophenyldialuric acid is obtained but instead, the corresponding anil and ether were isolated. Although alloxan 4-dimethylaminoanil is readily hydrolyzed by acids, the isomers described by H. and C. are all stable toward both concd. and dil. mineral acids. In no instance was there a cleavage of the azomethine into its components but at the most an oxidation to a benzimidazole deriv. The *o*-orientated Me_2N group stabilizes the C.N- linkage. These observations of the behavior of the isomeric anils corresponds with earlier published descriptions of the properties of other isomeric Schiff bases. Hydrolysis of anils depends often on the acid concn. Dimroth and Zoepritz (*Ber.* **35**, 984 (1902)) established this fact and explained it through an intermediate salt-forming product. Thus the fact that I cannot be split either by dil. or concd. acids and even forms a stable salt form is not the only reason for its stability. There is some extraordinary process exerted within the mols. W. A. Cook

The constitution of diazoamino compounds. Angelo Mangini. *J. Soc. Chem. Ind.* **58**, 327–30(1939).—Dwyer's observations (*C. A.* **33**, 1682[6,7]) that a "normal" and an "aci" (coördinated quinoid) structure exist in certain nitro diazoamino compds. are incompatible with the exptl. results found by M. The formation of Na and K salts of nitro diazoamino compds. contg. the NO_2 group in the *o*-, *m*- or *p*-position in either or both aromatic rings would imply the existence of true *m*-quinoid salts if "aci" forms exist. It is considered that in the salts the alkali metal is attached to N. Their intense color may easily be interpreted on the polar theory of unsatd. chromophores by analogy with other salts through N or O atoms. The salts are regarded as in a strongly ionoid intramol. state due to the simultaneous presence of 2 antiauxochromes, N:N and NO_2. The chromoisomerism which was observed in Ag and Hg salts of diazoamino compds., the relation between their color and the aromatic groups and substituents present and the recent spectroscopic studies by Wohl (*C. A.* **33**, 9300[2]) are discussed in connection with the probable structure of the diazoamino compds. From numerous exptl. results it is concluded that their isomerism is of a geometrical type. F. E. Brauns

The action of Grignard reagents on heavy metal salts. III. Mixed Grignard reagents and silver bromide. Lionel Joseph with John H. Gardner. *J. Org. Chem.* **5**, 61–7(1940); cf. *C. A.* **32**, 923[6].—The action of AgBr on a no. of pairs of Grignard reagents has been studied and it has been found that with a mixt. of PhMgBr and various alkylmagnesium bromide compds. (I) in all cases except where the alkyl group is *tert*-Bu, some of the unsym. product is formed. With $PhCH_2MgBr$ and I the yields of benzylalkanes increase and those of the bibenzyl decrease with the increase of the chain lengths of I, except in the case of *tert*-Bu. There is a definite relation between the course of the reaction and the electronegativities of the radicals involved. The significance of the results obtained on the detn. of the mechanism of the reaction is discussed. F. E. Brauns

Preparation of phenylarsenoxides in relation to a projected study to their chemotherapeutic activity. I. Monosubstituted derivatives. G. O. Doak, Harry Eagle and H. G. Steinman. *J. Am. Chem. Soc.* **62**, 168–70(1940).—A series of monosubstituted phenylarsenoxides has been prepd. with a view of studying their action against *Treponema pallidum*. *p*-$O_2NC_6H_4AsO_3H$ (I) in suspension in dil. HCl with SO_2 and KI gives *p-nitrophenylarsenoxide*. The *o-isomer* (II) is a light-yellow powder; addn. of Me_2CO to an alk. soln. gives the *di-Na salt*, with 2 mols. of H_2O; this may have a quinoid structure for when buffered with $NaHCO_3$ it could not be titrated with I. The soln. of II in alkali is deep-brown and does not show the toxicity or activity of the typical arsenoxide. The *m*-isomer gives only the arsenous acid which does not lose H_2O at 100°. Reduction of 10 g. of the *m*-isomer of I in concd. HCl gives the dichloroarsine-HCl which with NH_4OH yields *m-aminophenylarsenoxide*, which could be crystd. from alk. soln. by addn. of satd. NaCl soln. but could be freed from the salt only with difficulty; it softens at 62° without a definite m. p. *m-Hydroxyphenylarsenoxide*, from the *m*-dichloroarsine, with 2 mols. H_2O, lost at 150° for 12 hrs., giving a brittle pulverulent mass; *o*-isomer, m. 182–4° (cor.); H_2O_2 and $FeCl_3$ give a deep-wine color. *m-Chlorophenylarsenoxide*, a white powder on pptn. from EtOH with ice H_2O, which becomes sirupy on removal of the H_2O. The *o*-Cl isomer softens at 208° (Hiratuka, *C. A.* **33**, 1575[8], gives the m. p. as 140–50°). The *di-Na salt*, with 1 mol. H_2O, of *o*-$HO_3SC_6H_4AsO_3H$ results on heating the *o*-I deriv. with Na_2SO_3, acidifying to litmus and pptg. with EtOH; reduction in HBr and treating the dibromoarsine with NaOH gives the *Na salt* of *o-sulfophenylarsenoxide*. *o-Iodophenylarsenoxide*, m. 267°. C. J. W.

Modified Bart reaction. G. O. Doak. *J. Am. Chem. Soc.* **62**, 167–8(1940).—Whereas *p*-$HO_3SC_6H_4AsO_3H$ and the *p*-H_2NO_3S deriv. can be prepd. by the Bart reaction (Oneto and Way, *C. A.* **33**, 7750[8]), the reaction fails with the meta and ortho compds. However, the alc. Bart reaction (Scheller, Fr. pat. 624,028) may be successfully applied; anilines substituted in the ring by NO_2, CO_2H or SO_2NH_2 groups gave excellent results but the reaction failed with 2,6- and 3,5-$Me_2C_6H_3NH_2$ and with metanilic acid. The amine (0.1 mole) in 250 cc. abs. EtOH with 10 g. H_2SO_4 and 28 g. $AsCl_3$ at 0°, diazotized with a satd. aq. soln. of the calcd. amt. of $NaNO_2$, then treated with 1 g. CuBr, the mixt. stirred and warmed to 60° until the evolution of N ceased. By this method *p*-$H_2NO_2SC_6H_4AsO_3H$ results in 57% yield; the *m-isomer* is formed in 58% yield, m. 218–19° (in a bath preheated to 215°); it is recovered unchanged after heating with concd. HCl at 100° and is only partially hydrolyzed by cold concd. H_2SO_4 after 24 hrs. *m*-$O_2NC_6H_4AsO_3H$ results in 54% and the 3-nitro-4-methyl deriv. in 40% yield; *m*-$HO_2CC_6H_4AsO_3H$ is formed in 76% yield. C. J. West

Addition of *N*-haloamides to olefins. M. S. Kharasch and Hill M. Priestley. *J. Am. Chem. Soc.* **61**, 3225–32 (1939).—Halosulfonamides of the type $R'SO_2NBrR$ react with a large no. of olefins to yield products in which the Br atom takes the same position as the Br atom in the "normal" addn. of HBr to these substances. The *N,N*-dibromosulfonamides, on the other hand, add to olefins to give products in which the Br atom takes the same position as the Br atom in the "abnormal" addn. of HBr to these compds. $PhSO_2NBrMe$ (10 g.) and 8 g. $PhCH{:}CH_2$, warmed slightly and then cooled, give *1-phenyl-1-bromo-2-(N-methylbenzenesulfonamido)ethane*, a sirup which forms a hard glassy mass. *p*-$MeC_6H_4SO_2NBrMe$ (32 g.), added in 5 portions to 16 g. $PhCH{:}CH_2$, gives 32 g. of *1-phenyl-1-bromo-2-(N-methyl-p-toluenesulfonamido)ethane* (I), m. 67°; refluxing with AcONa in AcOH for 4 hrs. gives 3.5 g. (and 5 g. less pure) of the *1-AcO deriv.*, m. 94°, from 10 g. I; NaOH in EtOH, refluxed 0.5 hr., gives the *1-HO deriv.*, a pale-yellow, thick oil; reduction with Na

in AmOH gives 80% of *methyl(2-phenyl-2-hydroxyethyl)-amine*, m. 78°. Boiling 2.5 g. I in 2.5 cc. quinoline for 10 sec. gives 1.4 g. of *1-phenyl-2-(N-methyl-p-toluenesulfonamido)ethylene*, m. 106–7°; this also results by refluxing I with 3% EtONa for 10 min.; catalytic reduction gives a sirup which is hydrolyzed to $PhCH_2CH_2NHMe$; this amine results in 1 step by the use of Na in AmOH. The *N-benzylbenzenesulfonamido analog* of I is an oil; the *N-benzyl-p-toluenesulfonamido analog* m. 99°; boiling with 2% EtONa gives *1-phenyl-2-(N-benzyl-p-toluenesulfonamido)ethylene*, m. 122°; catalytic reduction gives the *ethane*, m. 105°, which with Na in AmOH gives $PhCH_2NHCH_2CH_2Ph$, whose HCl salt m. 265°. Passing a fairly rapid stream of isobutylene (II) through a suspension of 5 g. of $PhSO_2NBrMe$ in 10 cc. $CHCl_3$ at 40° for about 15 min. gives 4.8 g. of *1,1-dimethyl-1-bromo-2-(N-methylbenzenesulfonamido)ethane* (III), m. 95°; liquid II may also be used; the *N-methyl-p-toluenesulfonamido analog* of III m. 93° (9.7 g. from 10 g. amide). Boiling 8.4 g. of III in 16 cc. quinoline for 1 min. gives 3.8 g. of *1,1-dimethyl-2-(N-methylbenzenesulfonamido)ethylene* (IV) or *1-methyl-1-methylene-2-(N-methylbenzenesulfonamido)ethane* (V), a viscous oil which, on catalytic reduction and hydrolysis, yields iso-BuNHMe. The *N-methylbenzylsulfonamido analog* of III, m. 123°, results in 1.5-g. yield from 2 g. of the amide and 2 cc. of liquid II in 6 cc. $CHCl_3$ in a sealed tube at 40°; quinoline gives the *N-methylbenzylsulfonamido analog* of IV or V, m. 60°; catalytic reduction gives *N-methyl-N-isobutylbenzylsulfonamide*, m. 83°. CH_2Cl_2: $CHCl_3$ (15 g.) and 26 g. of $PhCH_2SO_2NBrMe$ give 26 g. of *1-bromo-1-chloro-2-(N-methylbenzenesulfonamido)ethane*, m. 90°; the *N-methyl-p-toluenesulfonamido analog* (VI), m. 90°. With 1% EtONa (refluxing 50 min.) VI gives *1-chloro-2-(N-methyl-p-toluenesulfonamido)ethylene*, m. 91°. p-$MeC_6H_4SO_2NBrMe$ (10 g.) and 10 cc. liquid C_3H_6 in 30 cc. $CHCl_3$, heated 30–40 min. at 70–80° in a sealed tube, give 8.5 g. of *1-(N-methyl-p-toluenesulfonamido)-2-bromopropane* (VII), m. 92°; removal of HBr with 2% EtONa, catalytic reduction and hydrolysis give MePrNH; the *N-methyl-N-propyl-p-toluenesulfonamide*, m. 40°. p-$MeC_6H_4SO_2NH_2$ (11.5 g.) and 6.9 g. of Br are treated with 27 cc. of 20% NaOH and the lower layer is dissolved in 60 cc. lukewarm $CHCl_3$; dropwise addn. of 15 cc. of $PhCH{:}CH_2$ gives 14 g. of *1-phenyl-1-p-toluenesulfonamido-2-bromoethane* (VIII), m. 167°; anethole gives *1-p-anisyl-1-p-toluenesulfonamido-2-bromopropane* (IX), m. 167°; isosafrole gives the *3,4-methylenedioxyphenyl analog* of IX, m. 153°. The action of 8 cc. of 20% aq. NaOH upon 11.5 g. of VIII in 40 cc. EtOH gives 8.6 g. of *N-(p-tolylsulfonyl)styrenimine* (X), m. 95°. VIII and Br with 20% aq. NaOH gives $CH_2BrCHPhNBrSO_2C_6H_4Me$ which with $PhCH{:}CH_2$ gives *1-phenyl-1-bromo-2-[N-(1-phenyl-2-bromoethyl)-p-toluenesulfonamido]ethane*, $PhCHBrCH_2N(SO_2C_6H_4Me)CHPhCH_2Br$, m. 158°. X in Et_2O, shaken with 15 cc. of aq. HBr, gives *1-phenyl-1-bromo-2-p-toluenesulfonamidoethane*, m. 111°; the *1-Cl deriv.* m. 137° and the *1-I deriv.* m. 67°. Catalytic reduction of X in MeOH gives *N*-phenylethyl-*p*-toluenesulfonamide (XI), m. 67°, which is hydrolyzed to $PhCH_2CH_2NH_2$; this results in 1 step by the use of Na in AmOH. Treatment of XI with Br and NaOH and then with $PhCH{:}CH_2$ gives *1-phenyl-1-bromo-2-(N-phenethyl-p-toluenesulfonamido)ethane*, m. 97°. Refluxing X with H_2O for 2 hrs. gives *N-(2-phenyl-2-hydroxyethyl)-p-toluenesulfonamide* (XII), m. 113°. X and Cl_3CCO_2H, warmed until soln. results, give *1-phenyl-1-trichloroacetoxy-2-p-toluenesulfonamidoethane*, m. 125°; *1-EtO analog*, m. 106°; *1-crotonoxy analog*, m. 85°; *1-AcO analog*, m. 105°, results from XII and AcONa in AcOH or from X and AcOH. XII with Na in AmOH yields 2-phenyl-2-hydroxyethylamine.

C. J. West

Sulfanilamide compounds. II. Arylidene derivatives of N^1-substituted sulfanilamides. H. G. Kolloff and James H. Hunter. *J. Am. Chem. Soc.* **62**, 158–60(1940); cf. *C. A.* **32**, 6232⁷.—The arylidine derivs. were prepd. in 73–100% yields by condensing $H_2NC_6H_4SO_2NHR$ with ArCHO in the absence of a solvent; the products were crystd. from C_6H_6, PhMe, $C_6H_4Me_2$ or Me_2CO-petr. ether, though in some cases the crude material was simply washed with suitable solvents. *Sulfanilamide derivs: N^4-benzylidene*, m. 176°; 4-MeO deriv., m. 192–3°; 4-Me_2N deriv., m. 226–7°; *N^4-benzylidene-N^1-phenyl*, m. 175–5.5°; *4-MeO deriv.*, m. 166°; *4-dimethylamino deriv.*, m. 231°; *N^4-benzylidene-N^1-(4-nitrophenyl) deriv.*, m. 192°; *4-MeO deriv.*, m. 213.5°; *4-dimethylamino deriv.*, m. 231°; *N^4-benzylidene-N^1-(2-pyridyl) deriv.*, m. 245–6°; *4-MeO deriv.*, m. 212–12.5°; *4-dimethylamino deriv.*, m. 238.2–40°. Biol. data are given which indicate that, in general, introduction of an arylidene group results in a slight, but not particular significant, decrease in both the antistreptococcal and antipneumococcal activity; the latter was diminished to a greater extent than the former. In every instance the toxicity was found to be lowered. C. J. W.

Some alkamine esters of disubstituted methylcarbamic acids. John J. Donleavy and James English, Jr. *J. Am. Chem. Soc.* **62**, 218–19(1940).—Ph_2CHBr and AgNCO in Et_2O, refluxed and stirred for 3 hrs., give 80% of Ph_2CHNCO (I), b_4 148°. I and the desired amino alc. in dry Et_2O, refluxed 3 hrs., give the carbamate, which is pptd. by HCl and recrystd. from Me_2CO; these were also prepd. by reaction of $Ph_2CHCOCl$ in Me_2CO at 0° with satd. aq. NaN_3, extg. the isocyanate with Et_2O and reacting with the alc. (64% yield). *Diethylaminoethyl diphenylmethylcarbamate-HCl*, m. 179°; *diethylaminopropyl ester-HCl*, m. 183°; *dibutylaminoethyl ester-HCl*, m. 136°; *β-piperidinoethyl ester-HCl*, m. 119°; *diethylaminoethyl α-phenylethylcarbamate*, b_5 178°; *diethylaminopropyl ester*, b_3 164°; *diethylaminoethyl isopropylcarbamate*, b_5 123–5°; *HCl salt*, m. 114°. The compds. are highly active *local anesthetics* of toxicity comparable to cocaine; they are somewhat irritating, however. C. J. West

Identification of some aromatic compounds through their picrates. Olier L. Baril. *Rept. New Engl. Assoc. Chem. Teachers* **41**, 15–18(1939).—A discussion of the value of picric acid as a reagent, sources and properties of picric acid, metallic picrates and org. picric acid derivs. 11 references. Leopold Scheflan

Preparation of *m*-halophenols. Herbert H. Hodgson. *J. Am. Chem. Soc.* **62**, 302(1940).—Commenting on the work of Natelson and Gottfried (*C. A.* **33**, 5385⁶), H. claims that the prepn. of m-BrC_6H_4OH is that covered by his Brit. pat. 200,714 (*C. A.* **18**, 274). C. J. West

Mercury and bromine derivatives of acetyl-*p*-phenetidine. Michele Ragno. *Ann. chim. applicata* **29**, 148–51(1939).—Fusion of 1 mol. of acetyl-*p*-phenetidine (I) with 3 and 4 mols., resp., of $Hg(OAc)_2$ gives tris(acetoxymercuri)- (II), and tetrakis(acetoxymercuri)acetyl-*p*-phenetidine (III). These form colloidal solns. in water, probably because of their high mol. wt. Treated with Br_2 in alk. soln. in proportions of 3 Br to each Hg, the corresponding tri- and tetrabromo derivs. (IV and V) of I are formed. II and III decompose on heating to 155° and 170°, resp., while IV and V melt at 165° and 268°, resp. A. W. C.

Monomercury derivatives of acetyl-*p*-phenetidine. Michele Ragno. *Ann. chim. applicata* **29**, 414–18(1939).—By heating equimol. solns. of acetyl-*p*-phenetidine and $Hg(OAc)_2$ in water, *3-(acetoxymercuri)-N-acetyl-β-phenetidine* (I) is formed, as white crystals, m. 169–70°. By elimination of the AcOHg group with Br, 3-bromophenacetin, m. 113–14°, results, thus proving the constitution of I, and also showing that the AcNH group has the same orienting effect as the OEt group. I does not form colloidal solns.

A. W. Contieri

Sulfonates of higher alkyl phenolic ethers. G. Spencer Hartley. *J. Chem. Soc.* **1939**, 1828–34.—Ethers of PhOH and MeC_6H_4OH were prepd. by refluxing with 0.6 equiv. of 0.5 *N* EtOH-KOH and 0.4 equiv. of alkyl bromide for 6 hrs.; the yields may be as high as 90%; Ph cetyl, m. 42°; *o*-, *m*- and *p*-tolyl cetyl, m. 21.5, 35 and 42.5°, resp.; *p*-tolyl dodecyl, m. 23.5°. Dioctyl ethers of dihydric phenols were prepd. from the phenol in 95% EtOH by adding in 5 portions 0.2 equivs. each of *N* EtOH-KOH and octyl bromide at intervals of 1 hr. and refluxing for an addnl. 2 hrs.; *o*-, m. 23.5°; *m*-, m. 37.5°; *p*-, m. 56°. Diethers of m-$C_6H_4(OH)_2$ were prepd. by refluxing the Na salts of the monoethers in EtOH with the equiv. of alkyl

bromide for 8 hrs.; the m. ps. of the dialkyl ethers are: C_6-C_8 12.5°, C_8-C_6 15°, C_8-C_8 37.5°, C_{10}-C_6 27°, C_{12}-C_4 29.5°, C_{14}-C_2 30.5°, C_{10}-C_8 31°, C_{12}-C_6 34°, C_{14}-C_4 34°, C_{16}-C_2 37.5°, C_{12}-C_{12} 60°, C_{16}-C_{16} 71.5°. Sulfonation of the ethers with a free position para to the ether group was carried out with H_2SO_4 at 70° with const. stirring. Salts were prepd. by neutralization with the appropriate base in EtOH and crystn. from EtOH with the addn. of H_2O. Acid titration tests, frothing in H_2O and soly. tests showed that resorcinol diethers were completely disulfonated by acid more concd. than 87% (by wt.) and not appreciably by acid less concd. than 79%; therefore 87% acid in the ratio of 330 cc. to 1 g.-mole of ether was used; no difference was noticed between the product of 10- and that of 30-min. reaction. Details are given of the purification of these derivs. *1,3-Dioctyloxybenzenedisulfonic acid*, with 6 mols. H_2O, m. 40° (high vacuum); it loses 5 mols. of H_2O on melting, resolidifies and then m. about 90°, losing the last mol. of water; the C_{12}-C_6 ether seps. with 2 mols. of H_2O. Sulfonation of ethers with no free position para to the ether group was effected with 1 mol. of $ClSO_3H$ in $CHCl_3$ to 1 mol. of ether. K salts were analyzed for a no. of mono- and disulfonates. All the salts are surface-active compds. and the series is designed to enable the effect of definite geom. changes in the surface-active ion to be examd. Only phys. properties relevant to purification and characterization are described. C. J. W.

Hydrolysis or alcoholysis of resorcinol ether sulfonic acids. G. Spencer Hartley. *J. Chem. Soc.* **1939**, 1834–6.—Resorcinol disulfonic acid dioctyl ether (I) with 6 moles H_2O, heated in abs. EtOH at 77° for 6 hrs., gives an almost quant. yield of the ether. The rate of complete reaction decreases with increasing H_2O content of the EtOH. Addnl. acid (such as HCl) had little effect in the driest alc., but considerably increased the rate when 6.5% of H_2O was present. In H_2O alone the soln. ($M/20$ of I) remained perfectly clear when kept at 100° for 12 hrs., even in the presence of HCl; when the monosulfonate was similarly treated in N aq. HCl, most of it was recovered as ether. In cellosolve and PrOH the rate of complete reaction of I is approx. the same as in EtOH; in iso-PrOH it is about 0.5 as great; at 100° the reaction in cellosolve proceeds 7 times as fast as at 77°; ether could be recovered after the acid had been heated in dioxane or MeCOEt, each contg. 5% H_2O. With an $M/20$ soln. of the anhyd. K monosulfonate in $N/3$ abs. EtOH-HCl, results were obtained which closely fitted the unimol. reaction velocity equation. It appears that the SO_3H group must be undissocd. and that it can then react with any HO group. The behavior of 4-cetyloxybenzenesulfonic acid, 5-methyl-2-cetyloxybenzenesulfonic acid and 1,2-dioctyloxybenzene-4-sulfonic acid in cellosolve is also described. C. J. West

Structure of cannabidiol, a product isolated from the marihuana extract of Minnesota wild hemp. I. Roger Adams, Madison Hunt and J. H. Clark. *J. Am. Chem. Soc.* **62**, 196–200(1940).—Minnesota wild hemp (cut after flowering had begun but before seed had "set" in the female tops) was air-dried for 6 weeks, beaten and the coarse stems removed. Countercurrent extn. with 95% EtOH in a series of 4 20-gal. crocks gave an ext. contg. 2 g. per 100 cc.; concn. at about 30° gave a red oil which, on distn. in a bath at 170–310°, b_3 100–220°; the petr. ether soln. was extd. with H_2O; removal of the petr. ether and fractional distn. finally gave a fraction b_2 175–95°, which is considered purified red oil (I). In C_5H_5N I yields about 33% of a *bis-3,5-dinitrobenzoate* (II), m. 106–7° (cor.), $[\alpha]_D^{25}$ −76° (0.057 g. in 5 cc. Me_2CO), of *cannabidiol* (III), $C_{21}H_{30}O_2$ or $C_{21}H_{32}O_2$, a pale-yellow resin, b_2 187–90°, d_4^{20} 1.040, n_D^{25} 1.5404, $[\alpha]_D^{25}$ −119° (0.0378 g. in 5 cc. 95% EtOH); III contains 2 active H atoms. III was liberated from II by the action of liquid NH_3 in PhMe in a bomb at room temp. for 5 hrs. Various color reactions are given for I and III, which indicate that the colors given by I are dependent in part on substances other than III. III gives a *bis*(*m-nitrobenzenesulfonate*), m. 119–20° (cor.); the same deriv. was obtained directly from I. Refluxing III with MeI and K_2CO_3 in Me_2CO for 4 hrs. and repeating the operation several times give, after a total of 134 hrs., the *di-Me ether* of III, pale yellow, b_2 175–7°, n_D^{25} 1.5254, d_4^{20} 0.9823, $[\alpha]_D^{25}$ −133° (0.0535 g. in 5 cc. 95% EtOH); using twice the theory of MeI and K_2CO_3 and boiling 8 hrs. give what appears to be a *mono-Me deriv.*, b_2 177–9°, n_D^{25} 1.5311, $[\alpha]_D^{25}$ −118° (0.0455 g. in 5 cc. 95% EtOH). Oxidation of III with $KMnO_4$ and $NaHCO_3$ in 50% aq. Me_2CO gives caproic acid, indicating the presence of the Am group in a phenolic ring. III is toxic but has no marihuana activity. The active I gives an analysis not substantially different from pure cannabinol (IV) isolated by Wood, Spivey and Easterfield (*J. Chem. Soc.* **69**, 539 (1896); **75**, 20(1899)). The structure of III and its relation to IV are discussed; half of the mol. is probably a dihydroxyamylphenyl nucleus, the other an unsatd. alicylic nucleus. C. J. West

Pyrogallol-acetone condensation products. A. v. Wacek and K. Kratzl. *Österr. Chem.-Ztg.* **42**, 286–9(1939).—Mono-ortho derivs. of pyrogallol were prepd. by converting the OH groups to acetals which were then substituted and hydrolyzed. Attention is called to the "gallacetonin" (I) of Wittenberg (*J. prakt. Chem.* **26**, 78(1882)) and to the product of Fabinyi and Szeki (*Ber.* **38**, 3527(1905)), having the formula $C_{21}H_{24}O_6$, and also to the fact that both were declared to be identical by Baker (*C. A.* **33**, 2520²) and not to be considered an acetal of pyrogallol but a spirohydrindene deriv. The authors confirm this assumption. I was prepd. by condensing the pyrogallol 1-acetate with Me_2CO to form gallacetonin acetate which was hydrolyzed to I. Various derivs. of I were prepd. The benzoates and benzenesulfonates of I were prepd. by dissolving I in 2 vols. of dry C_5H_5N and warming with BzCl or $PhSO_2Cl$ on a water bath for several hrs., after which dil. HCl was added and the pptd. product was digested with warm AcOH, and recrystd. from glacial AcOH. The benzoate m. 287 8° and the benzenesulfonate 213–16°. Attempts to prep. the acetal by condensation of pyrogallol and acetone in the presence of P_2O_5 failed. The Me deriv. of I was prepd. by boiling a mixt. of 1-methylpyrogallol, dry Me_2CO and P_2O_5 for 1 hr. The resulting liquid was decanted from the H_3PO_4, neutralized with 10% Na_2CO_3, steam-distd., extd. with Et_2O and fractionated. A yellowish oil, b_{17} 113–15°, was obtained. When pyrogallol 1-benzoate was acetylated a product recrystd. from alc. and m. 78° was obtained. The Bz group of this compd. cannot be sapond. without splitting off the acetyl group. Similarly by acetonating pyrogallol benzenesulfonate with Me_2CO and P_2O_5 a product resulted which was crystd. from alc. and m. 84°. The acetate of I was prepd. from pyrogallol 1-acetate in the manner outlined above for the prepn. of the Me ester with the addnl. step of neutralizing the phenol with NaOH after the Et_2O extn. The acetate b_{12} 123–8°. When this acetate was shaken with 5% KOH for 45 min. at room temp., acidified, extd. with Et_2O and evapd., cryst. leaflets (from H_2O), m. 89–90°, were produced. This product is pure white and is claimed to be I. It is readily sol. in alc., Et_2O, AcOH, C_6H_6, and less sol. in ligroin and H_2O. It also dissolves in alkalies and is pptd. by CO_2 and mineral acids. I was then reacted with BzCl in C_5H_5N; the product, crystd. from alc., m. 79°. Likewise, I, when heated with Ac_2O for 3 hrs., yields the acetate of I, crystd. from petroleum ether and m. 47–8°, b_{12} 150°. The condensation of 1-methylpyrogallol with MeCOEt was carried out according to the method for prepg. the methyl deriv. of I. A yellowish oil b_{12} 129–32° and having the formula $C_{11}H_{14}O_3$ resulted. Edward J. Mahler

Mono- and diesters of pyrogallol. A. v. Wacek and Franz K. J. Travnicek. *Österr. Chem.-Ztg.* **42**, 281–6 (1939).—Monoesters of pyrogallol (I) were prepd. by first protecting 2 of the OH groups and then allowing the esterification to take place. The inner carbonates of I were prepd. according to the method of Einhorn, Callinar and Pfeifer (*Ber.* **37**, 106(1904)) and transformed into the Ac, Bz and benzenesulfonyl compds. by reaction in pyridine. The monoesters were prepd. from the latter compds. by sapon. in water either on standing or by boiling. *o*-Diesters could not be formed by sapon. of triesters of the

type $C_6H_3(OR')(OR)_2$ (R and R' = Bz, Ac) because the latter were found to be too stable. However, the diesters could be prepd. as follows: The *2,3-carbonate 1-benzylcarbonate* (II), formed by treating the carbonate with $ClCO_2CH_2Ph$, was sapond. to form the 1-benzylcarbonate (III) which was acetylated in pyridine. On hydrogenation the 2,3-diacetate of III loses CO_2 and the $PhCH_2OCO$ radical in the form of PhMe, leaving the 1,2-diacetate of I. The following esters of I were prepared: *1-acetate 2,3-carbonate*, $C_9H_6O_5$ (IV), formed by introducing AcCl dropwise into the carbonate in cold pyridine while shaking, allowing to stand for 24 hrs., then pouring the mixt. into cooled dil. HCl, filtering the residue *in vacuo* and recrystg. it from ligroin, m. 121°. *Acetate*, $C_8H_8O_4$ (V), from IV heated with 3 parts water to 75° until soln. took place, evapd. *in vacuo*, the residue redissolved in Et_2O, evapd. and recrystd. from ligroin, m. 85°. *1-Acetate 2,3-dibenzoate*, $C_{22}H_{16}O_6$, from BzCl added to V in cold pyridine, allowed to stand for 22 hrs., heated to 80° for 1 hr., poured into ice-cooled dil. HCl, the ppt. dissolved in Et_2O, evapd. and the residue dissolved in C_6H_6, from which crystals appeared in 1–2 days, m. 124°. *1-Benzoate 2,3-carbonate*, $C_{14}H_8O_5$ (VI), prepd. like IV, crystals from ligroin-C_6H_6, m. 141°. *1-Benzoate*, $C_{18}H_{10}O_4$, from VI refluxed with 4 parts H_2O for 2 hrs.; the resulting oily ppt. crystd. on scratching the glass and then sepd. from C_6H_6 in fine crystals, m. 133°. *1-Benzenesulfonate 2,3-carbonate*, $C_{13}H_8O_6S$, prepd. like IV, crystals from ligroin-C_6H_6, m. 93°. *1-Benzenesulfonate*, $C_{12}H_{10}O_5S$, prepd. like the 1-benzoate above, and crystd. from C_6H_6, m. 122°. II, $C_{15}H_{10}O_6$, prepd. by adding $PhCH_2OCOCl$ dropwise to pyrogallol carbonate in $PhNMe_2$, heating to 50° for 4 hrs., pouring into ice-cold HCl and crystg. the ppt. from a 2:1 mixt. of ligroin-C_6H_6, m. 74°. III, $C_{14}H_{12}O_6$, from II heated in Me_2CO and H_2O to 60° for 4 hrs., evapd. and the ppt. recrystd. from ligroin-C_6H_6 (1·5), m. 110°. *2,3-Diacetate* (VII) of III, $C_{18}H_{16}O_7$, from AcCl added to III in cold $PhNMe_2$, allowed to stand for 5 hrs., poured into cold dil. HCl, and the ppt. recrystd. from ligroin-C_6H_6 (2.1), m. 105°. *1,2-Diacetate* of I, $C_{10}H_{10}O_5$, from VII hydrogenated in Me_2CO in the presence of Pd black to split off CO_2 and MePh, evapd., and crystd. from C_6H_6, needles, m. 115°.

Edward J. Mahler

Acylation of aldoximes. III. The configuration of diphenylcarbamyl and picryl ether derivatives prepared from syn aldoximes. Gertrude Vermillion, A. E. Rainsford and Charles R. Hauser. *J. Org. Chem.* **5**, 68–74(1940); cf. *C. A.* **34**, 3978.—According to Brady and co-workers (*C. A.* **20**, 179) the diphenylcarbamyl and picryl derivs. of α-aldoximes (I and II) prepd. from the Na salt have the anti configuration, for, when heated with alkali, nitriles are obtained. In the present work evidence is presented that I and II obtained from the Na salt of α-aldoxime have the syn configuration while the β-aldoximes under the same conditions give the β-derivs. which in the presence of alkali are decompd. immediately to nitriles. I and II are difficult to hydrolyze. The picryl ethers of α-3,4-methylenedioxybenzaldoxime on hydrolysis with alkali at room temp. give the corresponding α-aldoximes. Under the same conditions the isomeric β-deriv. is recovered practically unchanged, indicating that the β-aldoxime is not first formed and then isomerized, but that the α-aldoxime is formed directly. The pyridine-$BuNH_2$ test for configuration is not applicable to II. The results are in agreement with the hypothesis previously postulated (*C. A.* **34**, 3978) that the acylation of α-aldoximes in the presence of a sufficiently strong base involves no change in configuration. **IV. The benzoylation of syn and anti aldoximes.** Gertrude Vermillion, Earl Jordan and Charles R. Hauser. *Ibid.* 75–9.—The benzoylation of β-3,4-methylenedioxy-, β-3-nitro- and β-4-methoxybenzaldoxime is carried out in the presence of pyridine at 0° and room temp. and in all cases high yields of nitriles are obtained in addn. to small yields of α-derivs. in the first 2 cases. β-Aldoximes with BzCl in the presence of aq. alkali give benzoyl α-derivs. but in the presence of a H_2O-dioxane soln. or emulsion of alkali, nitriles are obtained. β-Aldoximes and BzCl in the presence of Et_3N give nitriles. α- and β-Aldoximes with BzCl in pyridine soln. give partially or entirely nitriles, but in the presence of Et_3N, β-aldoximes give nitriles and α-aldoximes entirely the Bz α-derivs. From these results it is concluded that, although changes of configuration may occur under certain conditions, no change takes place when either α- or β-aldoximes are benzoylated in a sufficiently basic soln.

F. E. Brauns

Nitrones. V. The action of potassium cyanide on carbonamidic nitrones. Vito Bellavita and Nerina Cagnoli. *Gazz. chim. ital.* **69**, 583–94(1939); cf. *C. A.* **34**, 10042.—Four new carbonamidic aldonitrones were prepd. by a reaction already known, i. e., by the reaction of NH_2OH, HCNO and the aldehyde (cf. Conduche, *Compt. rend.* **140**, 434–36; *Bull. soc. chim.* **35**, 418–30(1906); *C. A.* **2**, 999), and they were then made to react with KCN. The latter reaction is: $RCH{:}N(:O)CONH_2 + KCN \rightarrow RCH{:}NCONH_2 + KCNO$. The $RCH{:}NCONH_2$ compds. are a hitherto unknown type of ureides, and in the expts. almost 100% yields of the ureides were obtained. This reaction of nitrones is not new but has been known only of a few phenylnitrones (cf. *Rend. accad. Lincei* **1930, I**, 197) and cyclic nitrones (cf. *C. A.* **5**, 502), and even in the present expts., nitrones derived from hydroxylated aldehydes did not react thus. With Ac_2O, these new ureides form, when cold, $RCH{:}NCONHAc$ compds., when hot, $RCH{:}NCONAc_2$ compds., both stable in boiling aq. acids and bases. With BzCl, the ureides form stable $RCH{:}NCONHBz$ compds. With $COCl_2$, the ureides form dibenzalcarbonyldiureas of the $CO(NHCON{:}CHR)_2$ type, which will be described in a later paper. The ureides do not react with alk. hypobromites or with HNO_2. Detns. of the N of the ureides gave, in practically all cases, values approx. 3% below the calcd. values, because in the combustion with CuO, as in acid and alk. hydrolysis, these ureides form HCN as well as normal hydrolytic products. Although the reaction with KCN depends primarily on the nitrone group, it is also influenced by the character of the monovalent radical united to the N atom. A mixt. of *p*-ClC_6H_4CHO (10 g.), KCNO (12 g.) and $NH_2OH.HCl$ (12 g.) in a little water, kept ice-cold and agitated for 2 hrs. and the product purified by charcoal and EtOH, yields the *carbonamidic nitrone*, *p*-$ClC_6H_4CH{:}N(:O)CONH_2$, decomp. 132–5°. *p-Dimethylamino analog*, lustrous, decomp. 164–5°. *β-Resorcylaldehyde carbonamidic nitrone*, decomp. 132–5°, and in boiling water or EtOH. *Bourbonal carbonamidic nitrone*, decomp. 139–40°. These nitrones and some others already known were made to react with equimol. wts. of KCN. Alc. $PhCH{:}N(:O)CONH_2$ and KCN, refluxed for 0.5 hr., evapd., satd. aq. $NaHSO_3$ added, extd. with Et_2O, the ext. evapd., and the residual oil steam-distd. (it decomp. when distd. *in vacuo*), yield *benzylideneurea*, oil, hydrolyzed by H_2SO_4 to BzH, CO_2, NH_3 and HCN. An aq. suspension with BzCl yields, after making alk. by Na_2CO_3, *benzoylbenzylideneurea*, m. 103°. *Cinnamylideneurea*, lustrous, m. 75–7°; *Bz deriv.*, silky, m. 123°. Although *p*-iso-$PrC_6H_4CH{:}N(:O)CONH_2$ has been reported to decomp. at 121–2° (cf. *C. A.* **2**, 999), the compd. prepd. by B. and C. decompd. at 143–5°. With KCN it forms *cumylideneurea*, m. 110°, which, with BzCl and Na_2CO_3, forms the *Bz deriv.*, m. 125°. *o*-$O_2NC_6H_4CH{:}N(:O)CONH_2$ and KCN yield *o-nitrobenzylideneurea*, m. 103°; with cold Ac_2O + NaOAc it forms the *Ac deriv.*, m. 111°; with hot Ac_2O + NaOAc it forms the *di-Ac deriv.*, m. 70°; *Bz deriv.*, lustrous, m. 123°. *m-Nitrobenzylideneurea*, m. 123.5°; *Ac deriv.*, m. 131°, turns yellow on exposure to light; *Bz deriv.*, lustrous, m. 175°. *p-Chlorobenzylideneurea*, m. 112°; *Ac deriv.*, m. 73°; *Bz deriv.*, lustrous, m. 147°. *o*-$HOC_6H_4CH{:}N(:O)CONH_2$ and KCN in MeOH, heated and the oil distd. *in vacuo*, yields *salicylideneurea*, viscous lemon-yellow liquid, b_{25} 125°; *Bz deriv.*, lustrous, m. 118°. *Anisylideneurea*, m. 66–7°, is sapond. by concd. acids and bases only with difficulty; *Ac deriv.*, m. 51°; *Bz deriv.*, lustrous, m. 110°. *p-Dimethylaminobenzylideneurea*, silvery, m. 147°, turns brown on exposure to light; *Bz deriv.*, m. 152°; *Ac deriv.*, m. 180°. *Piperonylideneurea*, lustrous, m. 113.5°, sweet taste; *Ac deriv.*, lustrous, m. 108–9°; *Bz deriv.*, m. 167°. *4,3-HO(EtO)C₆H₃CH:NCONH₂*, straw-colored oil; *tri-*

Bz deriv., lustrous, m. 141°. *Furfurylideneurea*, silky, decomp. 132–3°; *Bz deriv.*, lustrous, m. 135°. C. C. D.

Addition of methoxyamine to α,β-unsaturated ketones and the rearrangement of β-methoxy amino ketones. A. H. Blatt. *J. Am. Chem. Soc.* **61**, 3494–9(1939).—$MeONH_2$ adds readily and reversibly to PhCH:CHBz (I) and a no. of its analogs which contain a substituent in the *p*- or *p'*-position to furnish solid β-methoxy amino ketones. No catalyst is needed; when a strong base is added, the reaction does not stop with the formation of this deriv. Bispropiophenones are also formed occasionally. $MeONH_2$ (2.5 g.) and 10.4 g. I in 25 cc. EtOH, boiled 3 hrs., give 78% of *β-phenyl-β-methoxyaminopropiophenone* (II), m. 54–5°; if the soln. is heated to 35° and then allowed to stand at room temp. for 18 hrs., the yield of II is 64%; there also results from 41.6 g. I 2.5 g. of *β,β'-methoxyiminobis(β-phenylpropiophenone)* (III), m. 178–9°; III also results in 0.6-g. yield from 1 g. I and 1.2 g. II in abs. EtOH on standing at room temp. for 67 days; vacuum distn. of III gives I. Distn. of II at 75 mm. gives I and $MeONH_2$. II may be pptd. unchanged from concd. H_2SO_4 by addn. of H_2O and alkali; the *HCl salt*, m. 133 4°, ppts. from *N* HCl but the HBr salt or picrate could not be prepd. The structure of II follows from its oxidation with NaOCl in the cold to the *monoxime Me ether* (IV) of CH_2Bz_2, m. 114 15°; IV was synthesized from CH_2Br_2 and $MeONH_2.HCl$ on boiling in EtOH for 2 hrs. (the *dioxime*, m. 57.5–8.5°, also results) and from PhC:CBz and $MeONH_2$. The equil. in the addn. reaction usually is quite favorable to the formation of the addn. product, which can be formed at room temp. or in boiling EtOH; in the presence of BzII the addn. reaction is reversed and the unsatd. ketone is regenerated, the addn. compd. acting as an oximating agent. PhCH·CHCOC$_6$H$_4$Me-*p* at room temp. gives 60% of *β-phenyl-β-methoxyamino-p-methylpropiophenone* (V), m. 43–4°; *p*-MeC$_6$H$_4$CH CHBz gives only *β,β'-methoxyiminobis(β-p-tolylpropiophenone)*, m. 185 6°. PhCH·CHCOC$_6$H$_4$Cl-*p* gives 70% of the *p-chloropropiophenone analog* (VI) of II, m. 51–2°; *p*-ClC$_6$H$_4$CH CHBz gives 86% of the *p-chlorophenyl analog* (VII) of II, m. 67 8°. PhCH CHCOC$_6$H$_4$OMe-*p* gives 65% of the *p-methoxypropiophenone analog* (VIII) of II, m. 52–3°, and the *p-MeO deriv.* of III, m. 183–4°. PhCH CHCOC$_6$H$_4$Br-*p* gives 83% of the *p-bromopropiophenone analog* (IX) of II, m. 66–7°, and *p*-BrC$_6$H$_4$CH CHBz gives 63% of the *β-p-bromophenyl analog* (X) of II, m. 52 3°. Soln. of II and its analogs in Ac_2O (warming for 1–2 min. in some cases) gives the *Ac derivs.* in quant. yield: II m. 94.5–5.5°, V m. 118–19°, VI m. 142–3°, VII m. 91–2°, VIII m. 115 16°, IX m. 157–8°, X m. 91 2°; the *p-methoxyphenyl analog* of II m. 130–1°. The Ac deriv. of IX, distd. at 15 mm., gives *p*-PhCH·CHCOC$_6$H$_4$Br which also results from the Ac deriv. and 1 equiv. of MeONa in MeOH in the cold. One equiv. of the methoxyamino ketone in 2 equivs. of 2 *N* MeONa (with addn. of MeOH for soln. if necessary), kept at 60° for about 10 min. and then allowed to stand overnight at room temp., gives α-aminobenzalacetophenones. II gives 94% of PhCH:C(NH_2)Bz, m. 100–1°; *α-aminobenzal-p-methylacetophenone*, m. 92–3°, 64%; *p-Cl analog*, m. 81–2°, 66%; *p-Br analog*, m. 114 15°, 83%; *α-amino-p-chlorobenzalacetophenone*, m. 88–9°, 80%; *p-Br analog*, m. 114–15°, 90%. C. J. West

Restricted rotation in aryl olefins. I. Preparation and resolution of β-chloro-β-(2,4,6-trimethyl-3-bromophenyl)-α-methylacrylic acid. Roger Adams and M. W. Miller. *J. Am. Chem. Soc.* **62**, 53–6(1940).—Bromomesitylene (I) and $(EtCO)_2O$ with $AlCl_3$ in CS_2 give *bromopropiomesitylene* (II), b_3 127–9°, d_{24}^{24} 1.2956, n_D^{20} 1.5490; cleavage of the EtCO group by refluxing with H_3PO_4 for 12 hrs. and nitration give a di-NO_2 deriv. of I, m. 199.5–201.5° (all m. ps. cor.), identical with that from the nitration of I (Fittig and Storer, *Ann.* **147**, 8(1868), give 189–90°). Reaction of II with EtMgBr, followed by carbonation, gives 51% of *α-methyl(2,4,6-trimethyl-3-bromobenzoyl)-acetic acid*, m. 123–4° (decompn.); warming with PCl_5 in $POCl_3$ for 1 hr. gives 53% of *β-chloro-β-(2,4,6-trimethyl-3-bromophenyl)-α-methylacrylic acid* (III), m. 157–8°. III and $ClSO_3H$ at −10° give 53% of the *5-chlorosulfonyl deriv.* (IV), m. 188–9°; III and liquid Br at 0° for 20 min. give the *3,5-di-Br deriv.* (V), m. 228–9°. III (10 g.) and 10 g. quinine (VI) in 150 cc. EtOH give 8.45 g. of *l*-VI.*d*-III which, recrystd. twice from EtOH, has $[\alpha]_D^{25}$ −46.8° (0.0995 g. in 25 cc. abs. EtOH); decompn. of 5.2 g. of the salt with 10 cc. concd. HCl in 100 cc. H_2O gives 2.4 g. of *d*-III, m. 155–6°, $[\alpha]_D^{25}$ 52.6° (0.0998 g. in 25 cc. EtOH), 69.4° (0.1008 g. in 25 cc. AcOH); the oily salt fraction gives the *l*-III, $[\alpha]_D^{25}$ −54° (0.0994 g. in 25 cc. EtOH). Refluxing the *d*-III in abs. EtOH for 15 hrs. or in glacial AcOH for 12 hrs. causes no change in rotation. Bromination of either the *d*- or *l*-III gives the inactive V. $ClSO_3H$ gives a *d*-IV, m. 183–4°, $[\alpha]_D^{25}$ −8.6°, and a *l*-IV, $[\alpha]_D^{25}$ 10° (0.1018 or 0.1002 g. in 25 cc. C_6H_6). The asymmetry of the mol. is undoubtedly due to restricted rotation between the C of the C_6H_6 ring and the olefinic C to which it is attached. Necessity for unsym. substitution in the C_6H_6 ring is demonstrated by the action of Br and $ClSO_3H$; Br gives a di-Br compd. with sym. substitution and an inactive product; $ClSO_3H$ gives a product still contg. an unsym.-substituted C_6H_6 and thus an active product. This compd. is typical of a general class of aryl olefins which should be capable of resolution. C. J. West

Interaction of sulfuryl chloride with arylamides of aromatic acids. II. Orienting influences of groups in substitution reactions in aromatic compounds. N. W. Hirwe, G. V. Jadhav and D. R. Sukhtankar. *J. Indian Chem. Soc.* **16**, 281–4(1939); cf. *C. A.* **33**, 5827².—Mixts. of 5 g. of aromatic arylamides, *o*-RC$_6$H$_4$CONHR′ (R = OH, OMe, Me and Cl; R′ = Ph, *o*-, *m*- and *p*-MeC$_6$H$_4$, *o*-MeOC$_6$H$_4$, and *m*-ClC$_6$H$_4$) and 1, 2 or 4 equivs. of SO_2Cl_2 in 40 cc. benzene were refluxed for 4–5 hrs. The reaction products were fractionally crystd. from alc. and identified by hydrolysis, synthesis or formation of Ac derivs. With derivs. of *o*-HOC$_6$H$_4$CO$_2$H, SO_2Cl_2 gives Cl derivs. contg. Cl in both the acidic and basic parts of the mol. By varying the proportion of reactive SO_2Cl_2 it is shown that the Cl first enters in the *p*-position to the OH group or NHCOR group and then in the *o*-position to these groups according to the nature of the reacting amide. Arylamides of *o*-RC$_6$H$_4$CO$_2$H (R = MeO, Me or Cl) gave only Cl substitution in the basic group. The following compds. were prepd.: *5-chloro deriv.* of salicylanilide (I), m. 203–4°; *4′,5-dichloro deriv.*, m. 215 16°; *2′,3,4′,5-tetrachloro deriv.*, m. 174–5°; *4′,5-dichlorosalicyl-o-toluide*, m. 17 *3,4′,5-trichloro analog*, m. 197–8°; *5-chlorosalicyl-m-toluide*, m. 144–5°; *4′,5-dichloro analog*, m. 221–2°; *3,4′,5,6′-tetrachloro analog*, m. 214 15°; *5-chlorosalicyl-p-toluide*, m. 215–17°; *2′,3,5-trichloro analog*, m. 164–5°; *4′-chloro-2-methoxybenzanilide*, m. 75–6°; *4′-chloro-2-methoxybenz-o-aniside*, m. 135–6°; *4′-chloro-o-toluanilide*, m. 132–4°; *2′,4′-dichloro analog*, m. 128°; *5-chloro-o-tolu-o-toluide*, m. 182°; *4′,6′-dichloro-o-tolu-m-toluide*, m. 120–1°; *2′-chloro-o-tolu-p-toluide*, m. 119–20°; *2,4′-dichlorobenzanilide*, m. 119–20°; *2,3′,4′-trichlorobenzanilide*, m. 143°. C. R. Addinall

The ozonization of cinnamic acid, sodium cinnamate, ethyl cinnamate and styrene. E. Briner and A. Gelbert. *Helv. Chim. Acta* **22**, 1483–90(1939)(in French); cf. *C. A.* **31**, 8520⁶; **33**, 535⁴, 6796⁸, 6813¹, 8068⁸.—Quant. ozonization of (1) PhCH $CHCO_2H$ in MeOH, (2) PhCH:$CHCO_2Et$ in CCl_4 and (3) PhCH:CH_2 in CCl_4 normally yields ozonides, which subsequently split into (1) BzOH and $OHCCO_2H$, (2) BzH and HO_2CCO_2Et and (3) BzH and HCO_2H, resp. As is generally the case when working with aq. solns., the ozonization of PhCH:$CHCO_2$-Na gives products (liberation of CO_2) which indicate a true destruction of the ozonide. The higher the degree of polymerization of styrene, the greater is the difficulty of ozonization. Ruth Berggren

Synthesis of some alkamine esters of alkylthiobenzoic acids. John J. Donleavy and James English, Jr. *J. Am. Chem. Soc.* **62**, 220–1(1940).—The alkylthiobenzoic acids were prepd. by reacting the diazonium salt with K Et xanthate and alkylation of the reaction mixt. with CH_3N_2, $MeCHN_2$ or Pr or Bu halides in yields of 80–100%: *m-Et* (monohydrate), m. 98°; *o-* and *m-Pr*, m. 121 and 104°; *o-* and *m-Bu*, m. 98 and 103°. *Acid chlorides* were prepd.

with PCl_5 as light yellow, viscous oils: *m-Me*, b_3 123°; *o-*, *m-* and *p-Et*, b_3 133, 127 and 118°, resp.; *o-* and *m-Pr*, b_3 145 and 138°; *o-* and *m-Bu*, b_3 151 and 147°. Refluxing the chlorides with 1 mole quantity of the desired amino alc. and about 2 moles of C_5H_5N for 3 hrs. gives the alkamine esters; the b. p. of the ester and m. p. of the *HCl salt* are given in each case. *o-Ethylthiobenzoates:* *β-diethylaminoethyl* (I), b_3 158°, m. 128°; *γ-diethylaminopropyl* (II), b_3 184°, m. 121°; *β-piperidinoethyl* (III), b_3 197°, m. 134°; *β-dibutylaminoethyl* (IV), b_3 187°, m. 116°. *o-Propylthiobenzoates:* I, b_3 176°, m. 123°; II, b_3 182°, m. 87°; III, b_3 190°, m. 128°; IV, b_3 208°, m. 93°; *o-butylthiobenzoates:* I, b_2 180°, m. 117°; II, b_2 193°, m. 96°; III, b_2 198°, m. 120°; IV, b_3 193°, m. 107°; *m-methylthiobenzoates:* I, b_5 185°, m. 153°; II, b_4 190°, m. 149°; *m-ethylthiobenzoates:* I, b_2 163°, m. 135°; II, b_3 170°, m. 125°; III, b_3 173°, m. 139°; *m-propylthiobenzoates:* I, b_3 172°, m. 110°; II, b_3 183°, m. 94°; III, b_3 182°, m. 116°; *m-butylthiobenzoates:* I, b_4 200°, m. 110°; II, b_3 194°, m. 96°; III, b_3 198°, m. 114°; *p-ethylthiobenzoates:* I, b_3 160°, m. 166°; II, b_3 185°, m. 138°. These compds. are less toxic than procaine; many surpass this local anesthetic in duration of anesthesia when tested on the rabbit cornea; the *o-* and *m*-ethylthio and methylthio compds. are more active than the corresponding *p*-derivs. C. J. W. 1

Constitution of usnic acid. Yasuhiko Asahina. *Proc. Imp. Acad.* (Tokyo) **15**, 311-14(1939).—A review is given of the structure of usnic acid, its di-Ac deriv., decarbusnol, usnolic acid, usnonic acid and dihydrousnic acid; 9 formulas are proposed. C. J. West 4

Geometrical inversion in the acids derived from the coumarins. VII. The behavior of acetylcoumaric acids. P. Suryaprakasa Rao, V. D. Nageswara Sastri and T. R. Seshadri. *Proc. Indian Acad. Sci.* **10A**, 267-74(1939); cf. *C. A.* **32**, 3362[2].—The transition of Ac derivs. of coumaric acids into coumarins (trans to cis inversion) under the influence of sunlight, heat and $HgCl_2$ has been studied. The Ac derivs. are prepd. with good yields (2.2 g. *acetylcoumaric acid* (I) from 2 g. coumaric acid) by acetylating the coumaric acids with AcONa and Ac_2O at 100°. At higher temps. (boiling Ac_2O) the yields are lower, especially for the substituted coumaric acids, owing to considerable conversion into the corresponding coumarins. *Acetyl-4-methylcoumaric acid* (II), m. 155°. *Acetyl-5-nitrocoumaric acid* (III), m. 217°. *Acetylpsoralic acid* (IV), m. 180-1°. *Acetylisopsoralic acid* (V), m. 210-11°. By exposing the acetylcoumaric acids in alc. to sunlight the corresponding coumarins are formed from I and II after 200 hrs. in 85-90 and 80-5% yield, resp., from III after 24, 48 and 200 hrs. in 5, 40 and 95-100% yield, resp. By heating I V 40-50° above their m. ps. the corresponding coumarins are obtained in 60-80% yield. Some resinous products are formed in addn. with evolution of CO_2. I-V boiled in alc. or aq. soln. with equimol. amts. of $HgCl_2$ give almost theoretical yields of the coumarins. Dora Stern 5

Addition reactions to conjugated systems. II. Caryophyllene and maleic anhydride. Norman F. Goodway and Trustham F. West. *J. Chem. Soc.* **1939**, 1853-5; cf. *C. A.* **33**, 1705[5].—Sandermann (*C. A.* **33**, 8698[6]) has suggested that the yellow color which always precedes the condensation of a diene and maleic anhydride (I) might be utilized to indicate the presence of diene constituents in essential oils but the results for a no. of simpler terpenes (caryophyllene (IA), α- (II) and β-phellandrene (III), α-pinene (IV), limonene (V) and 3-carene (VI)) show that the test is not applicable, all the terpenes developing some yellow color after the addn. of I in C_6H_6. Similarly the application of Fieser's color reaction (*C. A.* **32**, 1705[3]) of conjugated dienes with *p*-$O_2NC_6H_4N_2Cl$ gives a pos. reaction for VI; IA gives an orange-red color after 9 min., II after 3 min., III after 5 min. and VI after 7 min.; V gives a yellow color after 30 min., as does IV: the control gave a very pale yellow color after 30 min. The absorption spectrum of IA exhibits a max. at 2640-50 A., $\epsilon_{max.}$ 142 (in EtOH); from the low intensity it is considered that this is caused by 1-2% of some unsatd. impurity; the data are directly opposed to the presence of a compd. having conjugated ethylenic linkages, unless present only in traces. The adduct I-IA, boiled 8 hrs. with MeOH-HCl (satd. in the cold), gives a *di-Me ester*, b_3 180-3°, n_D^{25} 1.4960; the monoalkyl lactonic ester of the type derived from the normal adducts of II and bicyclohexenyl was not found. This result appears to throw doubt on the suggestion of Rydon (*C. A.* **33**, 5384[2]) that normal adduct formation takes place between IA and I and on the argument of diene addn. to a *cis*-butadiene system which involved a 7-membered ring structure for the parent terpene. C. J. West 6

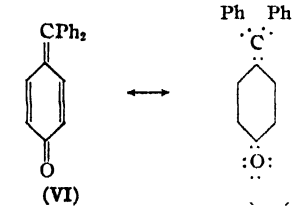
Addition of magnesium iodide to camphor and terpene derivatives. Sydney T. Bowden and Thomas F. Watkins. *J. Chem. Soc.* **1939**, 1961.—A mixt. of dry Et_2O, Mg and dry I is boiled until the soln. is nearly colorless; addn. of camphor gives the *complex* $5C_{10}H_{16}O.2MgI_2.Et_2O$, m. 108° (slowly heated) and then m. 176°. No reaction occurs on heating 3-bromocamphor with MgI_2 in Et_2O for 8 hrs. Carvone gives the *complex* $2C_{10}H_{14}O.MgI_2.Et_2O$, m. 85° and then 125°; at 200° decompn. occurs with evolution of I vapor. Santonin gives the *complex* $2C_{15}H_{18}O_3.MgI_2$, yellow, decomps. before melting at 175°. C. J. W. 7

Triterpenes. LI. Conversion of betulin into lupeol. L. Ruzicka and M. Brenner. *Helv. Chim. Acta* **22**, 1523-8(1939); cf. *C. A.* **33**, 8594[9].—Betulin monoacetate (I) (*C. A.* **33**, 1703[8]) was oxidized in 80% yield by CrO_3 in AcOH to *acetylbetulinaldehyde*, $C_{32}H_{50}O_3$ (II), crystals from Et_2O-MeOH, m. 199-200° (*in vacuo*), $[\alpha]_D$ 30.3° ($CHCl_3$). II exhibited absorption max. at 2850 A. (log ε 1.7 1.8) characteristic of the carbonyl group and gave a gold color with $C(NO_2)_4$. It is possible that the so-called ketone of Vesterberg (*C. A.* **26**, 5934[4]), m. 182-3°, $[\alpha]_D$ 30.26°, obtained by oxidation of I is identical with II. Treatment of II with $NH_2CONHNH_2.AcOH$ gave the expected semicarbazone (III) of II, crystals from $CHCl_3$-alc., m. 270 80° (*in vacuo*), and a difficultly sol., N-contg., unidentified by-product, m. 291-4°. Treatment of II with Na-alc. at 180° gave desoxybetulin, $C_{30}H_{50}O$ (IV), m. 212.5-14.5°, which was identical with lupeol (V); for IV $[\alpha]_D$ 27.2° ($CHCl_3$), for V 26.4° ($CHCl_3$) (*C. A.* **32**, 4563[5]). IV gave a benzoate, m. 268-71°, $[\alpha]_D$ 60.9° ($CHCl_3$), and an acetate, m. 215-17°, $[\alpha]_D$ 40.7° ($CHCl_3$), both of which were identical with the corresponding derivs. of V. Oxidation of IV by Kiliani's mixt. (*Ber.* **34**, 3564 (1901)) at room temp. gave desoxybetulone, $C_{30}H_{48}O$ (VI), m. 168-70.5°, $[\alpha]_D$ 60.8° ($CHCl_3$), which was identical with lupeone (VII) (*loc. cit.*). The oximes of VI and VII m. 268-73° (decompn.) and are identical. To the 3 types of triterpenes (squalene, β-amyrin and α-amyrin) V is to be added as a fourth. David E. Adelson 8

Method of reaction of metalloörganic compounds. IV. Rearrangement of diaryl ethers into *o*-arylphenols. Arthur Luttringhaus and Grete v. Sääf. *Ann.* **542**, 241-58(1939); cf. *C. A.* **32**, 8383[5]; **33**, 2890[3].—Ph_2O and PhNa (from 0.2 mole PhCl) in C_6H_6, shaken for various times at various temps., the product decompd. with MeOH and H_2O and extd. with 2 *N* NaOH, give on acidification of the alk. ext. *o*-HOC_6H_4Ph (I), m. 58°; the C_6H_6 layer, shaken with Claisen's alkali, gives *2,6-diphenylphenol* (II), m. 101°. The neutral portion yields a Ph_2O fraction (which contains not more than 15% Ph_2), *2-phenoxybiphenyl* (III), m. 49.5°, and *di-2-biphenyl ether* (IV), $b_{0.05}$ 155-65°, m. 116°. In a typical expt. in which the reaction was kept at 7° for 3 hrs. and at 65° for 8 hrs., mole % yields were: Ph_2O 4, III 9.1, IV 0.5, PhOH 26.4, I 45.5, II 9.8; yields are also given for other conditions of time and temp. The formation of III and IV can be explained only by the formation of *o*-alkali substitution in the Ph nucleus. This is shown by shaking Ph_2O with excess PhNa in C_6H_6 for 3 hrs. at 6° and passing CO_2 through the soln. (with cooling for 2 hrs.); esterification and distn. give $PhCO_2Me$ and *o*-$PhOC_6H_4CO_2Me$, b_4 135-40°; the formation of III results from the reaction of Ph_2O and the Na deriv. (PhONa also being formed). I results in part from an intramol. rearrangement of the Na deriv. of I to *o*-$PhOC_6H_4ONa$ (V) and also by extramol. reaction in which the Na deriv. reacts with III to give III and V. Reaction of III with PhNa in C_6H_6 (3 hrs. at room temp. 9

and 6 hrs. at 64°) gives 22.4 mole % of I, 26% of IV and 39% of II; PhOH was absent. The mechanism of the formation of the other products is discussed. *o*-PhC_6H_4-OK and PhBr or PhOK and *o*-IC_6H_4Ph with Cu at 210–20° give III, b_{14} 200–1°, m. 49.5; HNO_3 gives a NO_3 *deriv.*, m. 149°. *o*-PhC_6H_4OK and *p*-$O_2NC_6H_4Br$ give *2-(4'-nitrophenoxy)biphenyl*, pale-yellow, m. 87.5°. Ph-OK and 3-IC_6H_4Ph give *3-phenoxybiphenyl*, b_{14} 196–200°, m. 14–16°; *p*-PhC_6H_4OK and PhBr at 210° give *4-phenoxybiphenyl*, b_{14} 222°, m. 68°. IV was synthesized from *o*-IC_6H_4Ph and *o*-PhC_6H_4OK at 210-20°. The synthesis of II from the Na deriv. of nitromalonaldehyde is described; *Ph ether* of II, m. 119°; *Me ether*, m. 42°. C. J. West

Oxidation of certain heteronuclear-substituted polybromobiphenyls. Francis H. Case. *J. Am. Chem. Soc.* **61**, 3487–90(1939).—The following brominated biphenyls were prepd. by reduction of the NO_2 compds. with $SnCl_2$ in EtOH, acetylation with AcOH-Ac_2O-H_2SO_4, bromination in AcOH-AcONa, deamination with satd. $NaNO_2$ in boiling EtOH contg. dil. HCl and hydrolysis of the Ac deriv. by alc. HBr. 2-$BrC_6H_4C_6H_3(NH_2)Br$-4,3 gives *2,3-dibromobiphenyl* (I), b_3 165–8°; oxidation with CrO_3 in 75% AcOH of I and the 3,4'-isomer gives *m*- and *p*-$BrC_6H_4CO_2H$, resp. 2-$H_2NC_6H_4C_6H_4Br$-3 gives *2-amino-3,3',5'-tribromobiphenyl*, m. 111–12° (*Ac deriv.*, m. 185–6°); deamination gives *3,3',5'-tribromobiphenyl* (II), m. 112–13°; *3',4,5'-isomer* (III), m. 102–3°. 2,4,6,3-Br_3-$(H_2N)C_6HC_6H_4Br$-4, m. 93–4° (*Ac deriv.*, m. 260–1°); *2,4,4',6-tetrabromobiphenyl* (IV), m. 105–6°. *2-Acetamino-3'-bromobiphenyl*, m. 93–4°; *3,3'-dibromo-6'-acetaminobiphenyl*, m. 145–6°; *2',3,5'-tribromobiphenyl* (V), b_6 213–16°. *2,6'-Dibromo-3'-acetaminobiphenyl*, m. 142°; *2,2',5'-tribromobiphenyl* (VI), m. 77 8°. *2',4-Dibromo-5'-aminobiphenyl*, m. 91–2° (*Ac deriv.*, m. 163–4°); *2',4,5'-tribromobiphenyl* (VII), m. 77–8°. 2,4,6-$Br_3C_6H_2I$ and PhI give 2,4,6-tribromobiphenyl, b_4 190–8°, m. 65–6°; oxidation gives only *p*-$BrC_6H_4CO_2H$. 3-Nitrobenzidine yields a *monourethan*, m. 167–8°; *5-Br deriv.*, m. 167–8°; 3-nitro-5-bromobiphenyl, m. 171 2°; *3-NH₂ deriv.*, m. 89–90° (*Ac deriv.*, m. 142 3°). Oxidation of II and the 2,3',5'-isomer gives 3,5-$Br_2C_6H_3CO_2H$; III gives *p*-Br-$C_6H_4CO_2H$; VI yields 2,5-$BrC_6H_4CO_2H$ (VIII); V gives *m*-$BrC_6H_4CO_2H$ and VIII; VII gives *p*-$BrC_6H_4CO_2H$ and VIII; IV gives only *p*-$BrC_6H_4CO_2H$. The Br derivs. may be arranged in the order of decreasing stability toward oxidation as follows: 4-Br, 3,5-Br_2, (2,5-Br_2 and 3-Br), 2-Br and 2,4,6-Br_3. C. J. West



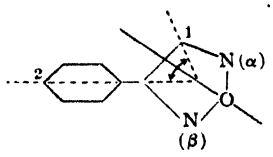
Optical rotatory powers of some 4-substituted benzohydrylamines. G. R. Clemo, C. Gardner and R. Raper. *J. Chem. Soc.* **1939**, 1958–60.—4-$MeC_6H_4CHPhNH_2$ gives a HCl salt m. 273°; the *d*-bromocamphorsulfonate, recrystd. repeatedly from 50% EtOH, m. 228°, $[\alpha]_D$ 57.5°; the base recovered in 1 expt. out of 6 had $[\alpha]_D$ −0.16° (EtOH, *c* 7.785); in the other 5 expts. the product was definitely inactive; the HCl also showed no measurable rotation. The base and $BrCH_2CO_2Et$, shaken with excess K_2CO_3 in abs. EtOH for 6 hrs., give *N-4-methylbenzohydrylaminoacetic acid*, m. 185°; $SOCl_2$ gives a *compd.* $C_{16}H_{18}ON$, m. 207°; this does not give cryst. salts with the commoner alkaloids. 4-BrC_6H_4Bz and $HCONH_2$, heated at 170–80° for 18 hrs., give *formo-4-bromobenzohydrylamide*, m. 127–8°; hydrolysis with satd. EtOH-HCl gives *dl-4-bromobenzohydrylamine* (I), b_1 155–60°, which is very unstable and absorbs CO_2 from the air; *Ac deriv.*, m. 153°. I and *d*-tartaric acid (II) give a *salt* which, cryst. 10 times from H_2O, m. 205°, $[\alpha]_D$ 7.2°; *l*-I, b_1 155–60°, $[\alpha]_D$ −7.1°, $[\alpha]_{5461}$ −12.8°, $[\alpha]_{4358}$ −24.6° (*Ac deriv.*, m. 183°); the recovered base from the mother liquors with *l*-II gives a *salt*, m. 205°, $[\alpha]_D$ −6.8°; *d*-I, $[\alpha]_D$ 10.2° (EtOH, *c* 1.347); *Ac deriv.*, m. 183°. The *4-Cl analog* (III) of I b_1 146°; *formyl deriv.*, m. 124°; *Ac deriv.*, m. 130–1°; *l*-III *d-tartrate*, m. 199°, $[\alpha]_D$ 9.8° (H_2O, *c* 1.735); *l*-III, b_1 145–50°, $[\alpha]_D$ −10.9°, $[\alpha]_{5790}$ −12.9°, $[\alpha]_{4358}$ −25.2° (EtOH, *c* 5.054); *Ac deriv.*, m. 169°; *d*-III *l-tartrate*, m. 199°, $[\alpha]_D$ −9.86° (H_2O, *c* 2.065); *d*-II, b_1 146°, $[\alpha]_D$ 10.8° (EtOH, *c* 2.184); *Ac deriv.*, m. 169°. The *4-I analog* (IV) of I b_1 173–6°; *formyl deriv.*, m. 143°; *Ac deriv.*, m. 170°; *l*-IV *d-tartrate*, m. 206°, $[\alpha]_D$ 3.85° (H_2O, *c* 1.234); *l*-IV, $[\alpha]_D$ −10.6°, $[\alpha]_{5790}$ −12.2°, $[\alpha]_{5461}$ −13.7°, $[\alpha]_{4358}$ −23.9° (EtOH, *c* 1.418); *Ac deriv.*, m. 195–6°; *d*-IV *l-tartrate*, m. 205°, $[\alpha]_D$ −3.8° (H_2O, *c* 1.044); *d*-IV, $[\alpha]_D$ 10.6° (EtOH, *c* 1.192); *Ac deriv.*, m. 195°. The presence of a small amt. of impurity in the *dl*-base has a marked effect on the success or otherwise of the resolution. The apparent failure to resolve $MeC_6H_4CHPhNH_2$ indicates that caution must be exercised in drawing conclusions from the failure to resolve $C_6D_5NHCH_2Ph$. Cf. *C. A.* **30**, 5950⁶. C. J. W.

Addition reactions of one-sided activated systems. R. Wizinger. *J. prakt. Chem.* **154**, 1–39(1939).—A review of the addn. compds. formed from diphenylethylene and its derivs. and related compds. with HCl, Cl_2, Br_2, I_2, ICl, NOCl, ClCN, $AcONO_2$, etc. References are given. C. J. West

Rearrangement of the triphenylmethyl ethers of *o*-cresol and brominated *o*-cresols. H. A. Iddles, W. H. Miller and W. H. Powers. *J. Am. Chem. Soc.* **62**, 71–3 (1940); cf. *C. A.* **34**, 4097.—6,2-$BrMeC_6H_3OH$ (20 g.) and 4.5 g. Ph_3COH in 135 g. AcOH, treated dropwise with 23 g. of H_2SO_4 and allowed to stand 3 weeks, give 55% of the *4-triphenylmethyl deriv.* (I), m. 149–51°; this also results from the bromination of 2,4-$Me(Ph_3C)C_6H_3OH$ in CCl_4 in 85.7% yield. I (1 g.) in 50 cc. C_6H_6, refluxed with 30 g. NaOH in 60 cc. H_2O while 2 g. Me_2SO_4 are added during 15 min., gives 0.8 g. of the Me ether, m. 183–4° (Boyd and Harvey, *C. A.* **22**, 1970). 2,4-$MeBrC_6H_3OH$ (II) and Ph_3COH with H_2SO_4 in AcOH give only 6.75% of the *6-triphenylmethyl deriv.*, m. 208–9°. 2,4,6-$MeBr_2$-C_6H_2OH (III) gives no condensation product with Ph_3COH. In an attempt to prep. the Ph_3C ether of 6,2-$BrMeC_6H_3OH$, the Na deriv. was treated with Ph_3CCl in Et_2O and the mixt. refluxed 5 hrs.; the only product was I. The Na deriv. of III did not react with Ph_3CCl. II and Ph_3CCl in C_5H_5N, on heating 10 hrs., give 48.7% of the *triphenylmethyl ether*, m. 113.5–14°; attempted rearrangement in AcOH-H_2SO_4 by $ZnCl_2$ or HCl was unsuccessful. This work substantiates the previous work (*C. A.* **34**, 4097) regarding the structure of the rearrangement product of *o*-$MeC_6H_4OCPh_3$. C. J. West

Stereoisomeric fuchsones. Wilhelm Bockemüller and Rudolf Geier. *Ann.* **542**, 185–203(1939).— α-$C_{10}H_7MgBr$ and 3,4-$Me(MeO)C_6H_3Bz$ give 50% of *phenyl(4-methoxy-3-methylphenyl)(1'-naphthyl)carbinol*, m. 131.5°; dry HCl in C_6H_6 gives 62.5% of the *chloromethane* (I), m. 102–4°; heating I at 120–30° for 1 hr. gives the form m. 155–60°; in a bath at 175° it melts in a few sec. Either form of I, heated in N for 8 hrs. at 110–30°, gives 85–90% of *7-α-naphthyl-7-phenyl-3-methylquinomethane*, yellow, m. 185–6°; the same compd. results in 44% yield on refluxing I in PhCl for 4 hrs.; only 1 form of this quinone was observed. α-$C_{10}H_7MgBr$ and 4,1-$C_{10}H_6(MeO)Bz$ give 18% of *phenyl-(4-methoxy-1-naphthyl)(1'-naphthyl)carbinol*, m. 224°; the *chloromethane*, yellow, m. 192° (decompn.); heating at 200° for 20 min. gives a *compd.*, violet needles, m. 217°, which is not the expected quinone. *p*-$ClC_6H_4CCl_2Ph$ and *o*-MeC_6H_4OH, 4 days at room temp., give 35% of *4-hydroxy-3-methyl-4'-chlorotriphenylcarbinol* (II), m. 112–13°; *acetate*, m. 124–5°. Heating II in PhCl for 2 hrs. gives *7-p-chlorophenyl-7-phenyl-3-methylquinomethane*, orange, m. 133–4°; isomeric forms were not observed. α-$C_{10}H_7CCl_2Ph$ (III) and *o*-MeC_6H_4OH, heated up to 90° (better yields are obtained by standing at 24 hrs. at room temp. and heating 1 hr. at 50°) and purified from C_6H_6, give 2 g. of a yellow compd. which, after a series of crystns., gives 2 isomeric *7-phenyl-7-α-naphthyl-3-methylquinomethanes*, yellow, m. 185–6°, and dark-yellow, m. 156–7°. III and α-$C_{10}H_7OH$ in C_6H_6, allowed to stand 2 days at room temp. and the dirty green-yellow reaction product subjected to a series of crystns. from C_6H_6-Et_2O, give 2 isomers of *(1,4-naphthoquinone)phenyl(α-naphthyl)methide*, citron-yellow, m. 197–8° (IV), and orange, m. 165° (V); the V after solidification m. 197–8°. If a hot C_6H_6 soln. of V is dild. with Et_2O, V seps. even though seeded with IV; IV behaves similarly. Warming a soln. of IV or V in C_6H_6 to 80° does not cause a rapid rearrangement of the

cis-trans isomers. *p*-$PhC_6H_4CCl_3Ph$ and α-$C_{10}H_7OH$ in C_6H_6 at 80°, followed by crystn. from PhMe-Et_2O, give 2 forms of *1,4-naphthoquinonephenyl-4'-biphenylmethide*, yellow, m. 165–72°, and orange-red, m. 161–4° (mixed m. p., 154–60°); the unsharp m. ps. are probably due to the transformation of 1 form into the other. Seeding a soln. of 1 form with a crystal of the other form has no effect upon the crystn. Reduction of either form with Zn in AcOH or catalytically yields *phenyl(4-hydroxy-1-naphthyl)(4'-biphenyl)methane*, m. 145–6°. These results indicate that in these fuchsone derivs. a mesomerism in the sense of the formulas VI ⟷ VII plays practically no role, the properties of the compds. being expressed by the structural formula VI.



(VI)

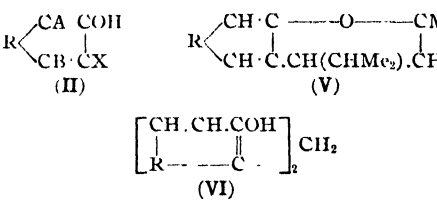
Preparation of rubicene from fluorenone with the aid of metallic calcium. V. I. Khmelevskiĭ and G. I. Fedorov. *J. Gen. Chem.* (U. S. S. R.) **9**, 1423 5(1939); cf. *C. A.* **33**, 7777⁹.—The substitution of Ca for Mg turnings in the method described in an earlier paper produced 13% rubicene. Similar reaction of 10 g. Ph_2CO with 2 g. Ca turnings yielded 20% *ms-diphenylanthracene*, m. 239°.

Chas. Blanc

Dioximes. CXXIV. Guido Tappi and Ugo di Vajo. *Gazz. chim. ital.* **69**, 615 20(1939); cf. Ponzio and T., *C. A.* **32**, 1682⁶.—Expts. on the mol. elec. moments (e. m.) of benzofurazans and of *o*-benzoquinone dioxime peroxides (cf. Milone and T., *C. A.* **33**, 7633⁹), which indicated that the latter are furoxans, made it possible that such measurements might also give a clue to the constitution of glyoxime peroxides, particularly pairs of isomeric methylaryl peroxides (cf. Ponzio, *C. A.* **23**, 375). Already pairs of certain methylaryl peroxides with low and high m. ps., resp., have been assigned MeC:N.O.O.N:CAr and MeC:N(:O)O.N.CAr structures, resp. (cf. Milone, *C. A.* **26**, 5564), but this decision was based on chem. reactions. In the present work, these types of compds. were studied further by comparisons of their e. m. Since methylphenylfurazan (I) and *p*-tolylfurazan (II) have almost equal e. m., the direction of the vectorial moment of phenylfurazan (III) should be approx. the bisector of the angle between the valence directions of the groups in 1- and 2-position. Hence III should have the configuration:

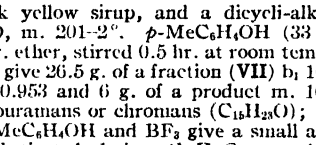
(β)

Since the addn. of a Me group in either of the 2 positions increases the e. m., the geom. problem of methylarylfurazans can be treated like that of the problem of a di-Ph deriv., the e. m. of which is equal to that of the heterocyclic C_8N_2O group. The e. m. of dimethylfurazan (IV) and diphenylfurazan (V) are significantly different, despite the fact that their resp. mols. have an element of symmetry; on the contrary V, II and I have almost the same e. m. Hence V does not have a planar configuration but rather one in which 3 rings (2 C_6H_6 rings and 1 heterocyclic ring) are located in different planes and without elements of symmetry. Based on the e. m. of various furazans and peroxides, the peroxides can be divided into 2 classes; 1 class comprises those having e. m. which differ from the e. m. of the corresponding furazans (diphenyl peroxide (VI), methylphenyl peroxide (VII) and methylanisyl peroxide (VIII) with low m. ps.); the 2nd class comprises those having e. m. approx. 0.75 higher than those of the corresponding furazans (dimethyl peroxide (IX), methylethyl peroxide (X), methylphenylglyoxime peroxide (XI) and methylanisylglyoxime peroxide (XII) with high m. ps.). The problem is however too complex to justify the conclusion that all the members of a particular class have identical structures. By calcg. the vector of I, and by assuming that the NO group increases the e. m. by 1.9 unit and that the extranuclear O atom is in α-position, it is found that the mol. has an e. m. of 4.97, which is close to the exptl. value of XI; therefore XI has a furoxan structure. With the O atom in β-position, the calcd. e. m. value is above 5.4, so that VII does not have a furoxan structure. The same conclusion is reached with respect to VIII and XII. Likewise calcns. indicate that neither IX nor X has a furoxan structure. Since the furoxan structure implies a higher electronic anisotropy than that for a dioxdiazine structure, it can be understood why true peroxides show a smaller increment (0.4) in their e. m. with respect to the corresponding furazans than the increment (0.75) of the corresponding furoxans. The increment of 0.75 caused by the NO group is close to that of *o*-benzoquinone dioxime peroxides, and therefore confirms the furoxan structure. VI has a non-planar configuration and it is not possible to establish its structure on a quant. basis. However, by taking into account the difference in e. m. between V and VI, it may be that the $C_2N_2O_2$ group has a dioxdiazine structure; if so, it would be in accord with arguments set forth by Milone (cf. *C. A.* **31**, 675⁵). In general then, a vector analysis of the e. m. of methylarylfurazans and of isomeric peroxides of methylarylglyoximes shows that only the peroxides with the higher m. ps. have a furoxan structure. On the contrary the e. m. of the isomeric methylaryl peroxides with the lower m. ps. and of dialkyl- and diarylglyoximes are in good accord with the e. m. calcd. on the basis that the $C_2N_2O_2$ group has a dioxdiazine structure.



C. C. Davis

Quinonemethides. K. Fries and E. Brandes. *Ann.* **542**, 48–77(1939).—3,5,4-$Me_3(HO)C_6H_2CH_2OH$, suspended in C_6H_6 and treated with HBr for 15 min. (during which soln. results) and then until no further HBr is taken up, gives 85% crude *2,6-dimethyl-4-bromomethylphenol* (I), m. 103–5°; I could not be purified because it loses CH_2Br_2 to give $[3,5,4\text{-}Me_2(HO)C_6H_2]_2CH_2$ (II); on standing in the air the color changes in 1 day through rose and red to brown. The *acetate* (III) of I m. 68–9° and is much more stable. I with MeOH, EtOH, H_2O, dil. Me_2CO, NaOH, EtONa or $SnCl_2$-AcOH at room temp. gives II. Distn. of I with Zn dust yields mesitol (IV). III with Zn and HCl in Me_2CO or Zn, AcONa or AcOAg in Ac_2O gives the di-Ac deriv. of II; II results even on heating with Cu in indifferent solvents instead of the expected VII. I (8.6 g.) in 100 cc. C_6H_6 and 10.9 g. of AcONa in 100 cc. H_2O, shaken 1.5 hrs., give 1.4 g. of a crude orange-red product; extn. with C_6H_6 gives 0.8 g. of *(3,5-dimethyl-4,1-benzoquinone)-1-(3',5'-dimethyl-4'-hydroxyphenyl)methide* (V), orange-red, m. 172–3°; NaOH gives a blue salt, sol. in H_2O with a violet color. The portion difficultly sol. in C_6H_6 is *3,5,3',5'-tetramethyl-4,4'-stilbenequinone* (VI), which seps. from C_5H_5N as deep-violet rods, m. 330°, and from $CHCl_3$ as a less deeply colored compd. with 0.25 mol. H_2O, m. 215°. The C_6H_6 mother liquors from the crude mixt. of V and VI give 3.6 g. (crude) *3,5,3',5'-tetramethyl-4,4'-dihydroxy-α,β-diphenylethane* (VII), which, crystd. from AcOH and repeatedly from C_6H_6, m. 166–7°; *di-Ac deriv.*, m. 150-1°. Reduction of VII with Zn in boiling AcOH gives *3,5,3',5'-tetramethyl-4,4'-dihydroxystilbene*, m. 239–40°; *di-Ac deriv.*, m. 237–8°. A suspension of 0.1 g. of VI in C_6H_6, treated with HBr without cooling, gives 0.15 g. of *3,5,3',5'-tetramethyl-4,4'-dihydroxy-1,2-bromoethane*, m. (crude) 176° (decompn.); it splits off HBr on heating in indifferent solvents and with dil. NaOH, H_2O, C_5H_5N or alcs. regenerates VI. Reduction of V with Zn in AcOH gives II. Heating 0.3 g. of V in 2 cc. AcOH



for 10 min. gives *3,3,5',5'-tetramethyl-4,4'-dihydroxydiphenylcarbinol acetate* (VIII), pale-yellow, m. 155–60° (decompn.); with Ac_2O-H_2SO_4 V gives the *4,4'-di-Ac deriv.* (IX) of VIII, m. 139–40°. V (0.1 g.) in 5 cc. Me_2CO and 3 cc. H_2O, allowed to stand several days (addn. of a little H_2O during this time) gives *3,5,3',5'-tetramethyl-4,4'-dihydroxydiphenylcarbinol*, m. 156–8° (decompn.). Passing HBr into 0.2 g. of V in 10 cc. AcOH without cooling until the whole forms a mass of crystals gives the *compd.* $C_{17}H_{19}O_2Br.H_2O$, deep blue-violet needles, m. 253–5°; H_2O regenerates V; Ac_2O-H_2SO_4 gives IX. IV and Br (0.03 mole of each) in 41 cc. AcOH-AcONa at −3° give *1,3,5-trimethyl-1-bromo-4-oxo-1,4-benzene dihydride* (X); it is reduced by Zn to IV; it liberates I from KI; after keeping some time the soln. does not give IV on reduction but a light-sensitive compd., whose *di-Ac compd.*, $C_{18}H_{20}O_3$ m. 186°. X, decompd. with ice H_2O, gives a yellow oil, sepd. by distn. into IV and II (identified as the di-Ac deriv.) and a *compd.*, $C_{18}H_{22}O_2$, m. 153° (*di-Ac deriv.*, m. 133°), which is probably an unsym. dihydroxydiphenylethane. Dibromomesitol (XI) with Br in AcOH-AcONa gives the *1,2,6-tri-Br analog* (XII) of X, yellow, m. 80–4° (decompn.); it liberates I from KI and on reduction yields XI. XII slowly rearranges at room temp. (quickly on heating) to dibromodimethyl-*p*-pseudophenol bromide (Auwers, *Ann.* **302**, 79 (1898)). XII and $PhNH_2$ in EtOH-AcONa give the *1-anilino-2,6-dibromo deriv.*, orange-yellow, m. 136°. XII (1 part) in 10 parts AcOH, treated at 0° with 2 parts coned. HCl, gives 91% of *2,4,6-trimethyl-3,5-dibromo-4-aminodiphenyl ether*, m. 153° (*HCl salt*, m. 298°; *Ac deriv.*, m. 233°). 4,6,2-$Me_2(HOCH_2)C_6H_2OH$ (5 g.) in C_6H_6 and HBr give 5 g. of *2-bromomethyl-4,6-dimethylphenol*, m. 73°; like the chloride (XIII) it does not yield the simple *o*-quinonemethide but gives the polymer $(C_9H_{10}O_2)_3$ (*C. A.* **1**, 2367). The *acetate* of XIII, b_{15} 151°, m. 30°; heating in C_6H_6 with Naturkupfer C for 24 hrs. gives the *diacetate*, m. 125°, of *o,o'-dihydroxybimesityl* (XIV), m. 167°; Br gives the *tetra-Br deriv.* (XV), m. 258°. Treating XIV in 2 *N* NaOH with $K_3Fe(CN)_6$ gives the *cyclic quinol ether*, m. 123°, which is reduced by Zn in AcOH to XIV; similarly XV gives the *cyclic ether* $C_{18}H_{16}O_2Br_4$ (XVI), yellow, m. 168° (identical with the 3,5-dibromo-4,6-dimethyl-1,2-quinonemethide of F. and K.); Zn in AcOH gives XV; AcCl gives a complicated reaction leading to the di-Ac deriv. of a trichlorobromodihydroxybimesityl. XVI and $PhNHNH_2$ in EtOH give the *compd* $C_{24}H_{28}O_2Br_3N_2$, red, m. 193°, in which 1 of the Br atoms in XVI is replaced by PhNHNH; this is quite stable toward acids and alkalies; Ac_2O and H_2SO_4 give a *di-Ac deriv.*, yellow-red, m. 221°; the *anilido compd.*, yellow, m. 206° (decompn.); heating with coned. HCl replaces the PhNHI group by an OH group; reduction with Zn in AcOH gives an anilinotribromodihydroxybimesityl. IV is conveniently prepd. (65% yield) by reduction of the *Ac deriv.*, m. 108°, of 2,6-di(chloromethyl)-4-methylphenol (XVII) (Auwers, *C. A.* **1**, 2577) with amalgamated Zn and HCl in Me_2CO. The Br analog of XVII in Et_2O, shaken with 2 *N* Na_2CO_3, first gives the deep-yellow soln. of the quinonemethide, which quickly becomes colorless with the production of the *compd.* $(C_9H_9OBr)_3$, m. 167°. HBr could not be added to the Br compd. in AcOH; the polymeric quinonemethide is formed as a dark elastic mass; action of Zn upon the AcOH soln. of the polymer did not give a homogeneous reaction product and IV could not be isolated. Shaking 1 part of 4,3,5,2,6-$MeBr_2(BrCH_2)_2C_6OH$ with 10 parts of 10% AcONa gives 60% of the *cyclic ether*, $C_{18}H_{14}O_2Br_6$, S-yellow, m. 194°, which is reduced by Zn in boiling AcOH to XV and on heating with HBr-AcOH for 2 hrs. at 115–20° yields 75% of 1,2-di[2-hydroxy-3-(bromomethyl)-4,6-dibromo-5-methylphenyl]ethane, m. 228° (*di-Ac deriv.*, m. 290°); heating with 20 parts of MeOH for 20 min. gives the corresponding *3,3'-di(methoxymethyl) deriv.*, m. 191°.

C. J. West

Cycli-alkylation of aromatic compounds by the Friedel and Crafts reaction. Herman A. Bruson and John W. Kroeger. *J. Am. Chem. Soc.* **62**, 36–44 (1940).—PhOH (29 g.), 55 g. $(CH_2CClMe_2)_2$ (I) and 3 g. $AlCl_3$ in 30 g. of petr. ether (b. p. 90–100°), stirred 1 hr. at room temp., heated on a steam bath for 2 hrs., treated with 2 g. $AlCl_3$, heated an addnl. 2 hrs. and treated with cold dil. HCl, give 80% of *5,5,8,8-tetramethyl-5,6,7,8-tetrahydro-2-naphthol* (II; R =  and A, B and X = H), m. 145–5.2°; $FeCl_3$ gives an emerald-green color; the *oxyacetic acid deriv.* (III) m. 164–5°; the *Et ether* (IV) b_5 132° (attempts to oxidize the ether with dil. HNO_3 gave a yellow NO_2 *deriv.*, m. 106–8°). Oxidation of II with $KMnO_4$ gives a small quantity of 1,1,4,4-tetramethyladipic acid, m. 190–3°, proof that no rearrangement of the entering group had occurred during the condensation with $AlCl_3$. The mother liquor from II yields a small quantity of the *benzochroman* (V), m. 240–1°. II and HCHO with HCl give the *methylenedinaphthol deriv.* (VI), m. 232°. PhOH also condenses with $[Me_2C(OH)CH_2]_2$, $(CH_2MeC{:}CH_2)_2$ and $Me_2C.CH_2.CH_2.CMe_2$ to give II. $PhOCH_2CO_2H$, I and $AlCl_3$ in $C_2H_4Cl_2$, stirred 1 hr. at room temp. and refluxed 5 hrs., give III. IV also results from PhOEt and I. Condensations were also carried out with the following phenols, the products having the general formula II (A, B and X are H except as indicated): *o-cresol* (X = Me), m. 125.5–6°; *m-cresol* (B = Me), m. 134–5°; *2,6-Me$_2$-C$_6$H$_3$OH* (X and A = Me), m. 164.5°; *pyrocatechol* (X = OH), m. 182–3°; *o-PhC$_6$H$_4$OH* (X = Ph), m. 98°; *o-cyclohexylphenol* (X = C_6H_{11}), m. 109–10°; *o-ClC$_6$H$_4$OH* (X = Cl), m. 103.5–4°; *m-HOC$_6$H$_4$OCH$_2$CH$_2$OCH$_2$CH$_2$Cl* (B = $CH_2CH_2OCH_2CH_2Cl$), m. 107–8° and 71–5°, sepd. by crystn. from petr. ether (b. p. 90–100°). *Diphenylene oxide* and I with $AlCl_3$ in petr. ether, stirred 8.5 hrs. at room temp. and refluxed for 1 hr., give a fraction b_4 170–240°, probably contg. a monocycli-alkylated deriv.,

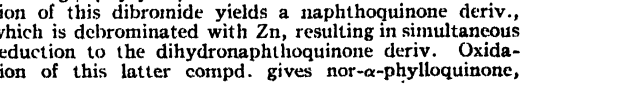
(II) (V)

(VI)

$C_{20}H_{22}O$, a thick yellow sirup, and a dicycli-alkylated compd., $C_{28}H_{36}O$, m. 201–2°. *p*-MeC_6H_4OH (33 g.), I and $AlCl_3$ in petr. ether, stirred 0.5 hr. at room temp. and 2 hrs. at 85–90°, give 26.5 g. of a fraction (VII) b_1 107–8°, n_D^{25} 1.5137, d_4^{25} 0.953 and 6 g. of a product m. 100–1°, believed to be couramans or chromans ($C_{18}H_{28}O$); $(CH_2CMeCH_2)_2$, *p*-MeC_6H_4OH and BF_3 give a small amt. of VII and a disubstituted deriv., $C_{23}H_{36}O$, m. 193–5°. PhOH (25 g.) and 54.5 g. of $[Me_2C(OH)CH_2]_2$, melted together and dropped into 96 g. of 77% H_2SO_4 at 10°, stirred at room temp. for 22 hrs. and at 85–95° for 1 hr., give 30 g. of *1,1-dimethyl-3-isopropyl-5-hydroxyindan*, b_5 160–5°, m. 97–8°; it gives an emerald-green color with $FeCl_3$-EtOH and forms a sparingly sol. Na salt from 10% NaOH; it does not react with HCHO but yields an oxyacetic acid deriv., m. 112–13°; it is unchanged by warming with $AlCl_3$ in petr. ether. 2,6-$Me_2C_6H_3OH$ similarly gives a *compd.*, $C_{16}H_{24}O$, b_6 156°. $(CH_2CPh_2OH)_2$ (8 g.), 10 g. *o*-cresol and 8 g. $AlCl_3$ in 100 ml. petr. ether, refluxed 14 hrs. and hydrolyzed with dil. HCl, give 6 g. of *5,5,8,8-tetraphenyl-3-methyl-5,6,7,8-tetrahydro-2-naphthol*, m. 330–2°, and a small amt. of *1,1,4,4-tetraphenyl-1,3-butadiene*, pale violet, m. 195–6°. 1,4-Dichlorocyclohexane, PhOH and $AlCl_3$ give *5,8-endoethylene-5,6,7,8-tetrahydro-2-naphthol(?)*, m. 124–7°. I (9 g.), 6.2 g. *p*-MeC_6H_4SH and 1 g. $AlCl_3$ in 30 g. petr. ether, refluxed 4 hrs., give 4 g. of *2,5-dimethylhexane-2,5-bis(p-tolyl sulfide)*, m. 128–9°; *m-isomer*, m. 105–6°; *o-isomer*, m. 75–6°; the *phenyl sulfide*, m. 79–80°. I (36 g.) in 78 g. C_6H_6, stirred at 30° or lower while 16 g. $AlCl_3$ is added, then stirred at room temp. for 21 hrs. and refluxed 2 hrs., gives 61% of *1,1,4,4-tetramethyl-1,2,3,4-tetrahydronaphthalene*, b_8 82–4°, b_{760} 248°, n_D^{25} 1.5278, d_4^{25} 0.9482. I (36 g.), 78 g. C_6H_6 and 1 g. $AlCl_3$,

refluxed 4 hrs., give *1,1,4,4,5,5,8,8-octamethyl-1,2,3,4,5,6,7,8-octahydroanthracene*, m. 220–2° (*NO_2 deriv.*, m. 259–61°); tetralin gives the *1,1,4,4-tetra-Me analog*, m. 90–1°. Hydrindene and I with $AlCl_3$ give *5,5,8,8-tetramethyl-5,6,7,8-tetrahydro-β-naphthindan*, m. 93–4°; $C_{10}H_8$ gives 80.5% of *1,1,4,4,7,7,10,10-octamethyl-1,2,3,4,7,8,9,10-octahydronaphthacene*, m. 319–20°; the *compd.*, $C_{18}H_{22}$, from PhMe and I b_4 95° and the *compd.*, $C_{18}H_{21}Cl$, from *o*-ClC_6H_4Me m. 104–5°. I and thiophene give a *tetramethyltetrahydrobenzothiophene*, b_6 94°. These compds. and methods may be of interest in the synthesis of higher polynuclear structures in *vitamin* and *hormone* research. The term *cycli-alkylation* is introduced to denote the formation of a new cycle by attachment of a satd. bivalent aliphatic group to an aromatic nucleus. C. J. W. 1

Steric hindrance in the addition of halogens to triaryl phosphites. Ludwig Anschütz, Horst Kraft and Kurt Schmidt. *Ann.* **542**, 14 28(1939).—2,4,1-$Br_2C_{10}H_5OH$ (20 g.) and 3 g. of PCl_3, heated 18 hrs. on the water bath and the product taken up in 100 cc. xylene at 100°, give about 20% of *tri(2,4-dibromo-1-naphthyl)phosphite* (I), m. 289°; a suspension in CCl_4 does not add Cl or Br (in 48 hrs.). The *1,6,2-isomer* of I, crystd. from CCl_4-Et_2O, m. 245° (15% yield); this also does not add Cl or Br. 1,6,2-$Br_2C_{10}H_5OH$ and PCl_3, heated 6 hrs. at 140–50°, give a yellow-brown smear which loses HCl in the air; that this is *tri(1,6-dibromo-2-naphthyl) phosphite dichloride* follows from the reaction with boiling H_2O for several hrs., which yields the *phosphate*, m. 200–1° (decompn.). 1-$C_{10}H_7OH$ (22 g.) and 7 g. PCl_3, heated 12 hrs. at 75–100°, give 45–50% of *tri(1-naphthyl)phosphite* (II), very hygroscopic, m. 91° (crystd. from xylene and washed with Et_2O); in Et_2O it absorbs Cl (2 hrs.) to give the *dichloride*, light green very hygroscopic liquid, purified by treatment with C_6H_6 and Et_2O; hydrolysis gives the *phosphate*, m. 145°; *dibromide*, ruby-red, very hygroscopic oil. The *2-isomer* of II m. 94° (crystd. from xylene and Et_2O); *dichloride*, yellow oil, hydrolyzed to the phosphate, m. 110–11°; *dibromide*, brownish red oil. 1-$C_{10}H_7MgBr$ and PCl_3 in Et_2O give 30–5% of *tri(1-naphthyl)phosphine* (III), m. 282° (from dioxane); it forms a *complex* with 1 mol. $CHCl_3$, m. 262° (lost on heating *in vacuo* at 98°) and with 1 mol. of CCl_4. The *dichloride* of III has been obtained only as the *complex* with 1 mol. of $CHCl_3$, m. 160° (decompn.), and with 1 mol. of CCl_4, each of which is only slightly hygroscopic; hydrolysis with dil. NaOH gives tri(1-naphthyl)phosphine oxide hydrate, which yields the oxide, m. 341–3°, on heating. The *dibromide* of III is prepd. by passing $CHCl_3$-Br over the surface of III; it is reddish, only slightly hygroscopic and does not form complexes with $CHCl_3$ or CCl_4. Anthrol and PCl_3, heated 5–8 hrs. at 100 10°, give 10% of *tri(1-anthranyl)phosphite*, greenish yellow, hygroscopic, decomps. 182–90°; 5% H_2SO_4 (boiling 0.5 hr.) gives anthrone; it does not add Cl or Br but a portion is hydrolyzed and oxidized; the products isolated include 10,10-dichloroanthrone, 10-bromoanthrone, anthraquinone and 1- and 3-bromoanthraquinone; H_3PO_3 is also formed, but no phosphates or H_3PO_4. Tri(9-anthranyl)phosphine could not be prepd. The color of the fluorescence of these compds. in ultraviolet light is given. The results indicate that the retardation of the reaction is less dependent on the electroneg. character of the *o*-Br atom than on the space relations of the aromatic residue. C. J. West 2



Water-soluble antihemorrhagic esters. Louis F. Fieser and Edward M. Fry. *J. Am. Chem. Soc.* **62**, 228–9 (1940).—A cooled suspension prepd. by slowly adding 0.6 cc. of $ClSO_3H$ to 2 cc. C_5H_5N and 5 cc. CCl_4, treated with 0.48 g. of vitamin K_1 hydroquinone (I) and boiled 10 min., gave a sticky solid, which was treated with 10 *N* NaOH, the C_5H_5N removed with Et_2O and the Na salt changed by EtOH-KOH to the *K salt of vitamin K_1 hydroquinonedisulfuric acid* (II), plates sol. in H_2O. *Na 2-methyl-1,4-naphthohydroquinonedisulfate* (III), with 2 mols. H_2O, and the *2,3-di-Me deriv.* (IV), with 2 mols. H_2O, were similarly prepd. I and $POCl_3$ in C_5H_5N give I-*diphosphoric acid* (V), which gives a gel with a small quantity of H_2O and a clear soln. with an adequate quantity. 2-Methyl-1,4-naphthohydroquinone and $POCl_3$ in C_5H_5N, followed by Na_2CO_3, give *Na 2-methyl-1,4-naphthohydroquinonediphosphate*, with 2 mols. H_2O; it is very hygroscopic and liquefies in moist air. II and IV were inactive in a dosage of 500 γ; V shows activity at dosages down to 25 γ but not at 10 γ; III shows antihemorrhagic activity at a level of 2 γ. A clinical trial with III is reported. C. J. West 3

Synthesis of vitamin K_1. Louis F. Fieser. *J. Am. Chem. Soc.* **61**, 3467–75(1939).—This gives the exptl. details of the prepn. of 2-methyl-3-phytyl-1,4-naphthoquinone (I) and the hydroquinone diacetate and dibenzoate previously reported in *C. A.* **33**, 8602[1]. 2,6-Dimethyl-1,4-naphthohydroquinone (4 g.) and phytol with $(CO_2H)_2$ give 0.54 g. of the *2-phytyl deriv.* analogous to I, viscous yellow oil with slight reddish tinge; *hydroquinone diacetate*, m. 55–6.5°. 2-Methyl-3-geranyl-1,4-naphthoquinone(II) is a viscous yellow oil; alc. KOH gives an intense indigo-blue color, changing to purple and then dull red; the use of myrcene gives a yellow oil. 2-Ethyl-3-phytyl-1,4-naphthoquinone is also a yellow oil. In these syntheses it is advantageous to sep. and purify the product in the reduced form prior to oxidation; the quinone is obtained in a pure condition without recourse to distn. or adsorption. Natural vitamin K_1 can be isolated very easily from alfalfa concentrates by a similar method. The 2-Et and 2,6-di-Me analogs are inactive in the chick-assay, whereas II shows moderate potency. Indications of a certain structural specificity are discussed and a tentative hypothesis is suggested concerning the action of 2-methyl-1,4-naphthoquinone. C. J. West 4

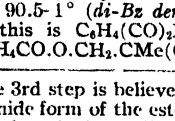
Synthesis of vitamin K_1. Louis F. Fieser. *Science* **91**, 31–6(1940); cf. preceding abstract. E. H.

Vitamin K-active derivatives of 2-methyl-1,4-naphthohydroquinone. S. Ansbacher, Erhard Fernholz and M. A. Dolliver. *J. Am. Chem. Soc.* **62**, 155–8(1940); cf. *C. A.* **33**, 6922[9].—2-Methyl-1,4-naphthoquinone (I), $EtCO_2H$, $(Et_2CO)_2O$, $EtCO_2Na$ and Zn dust, refluxed 30 min. in an oil bath at 160 70°, give 72% of *2-methyl-1,4-naphthohydroquinone dipropionate* (II), m. 74–5°. 2-Methyl-1,4-naphthohydroquinone (III) and BzCl in C_5H_5N, after standing 1 hr. and being heated at 110–20° for 30 min., give 84% of the corresponding *dibenzoate* (IV), m. 179°. Refluxing I with $PrCO_2H$, $(PrCO)_2O$, $PrCO_2Na$ and Zn for 1 hr. gives 55% of the *dibutyrate* (V), b_1 175–85°, m. 52–3°, also prepd. in 3.5 g. yield from 8.5 g. of III and PrCOCl in C_5H_5N (refluxing 1 hr.). III and iso-PrCOCl give 69% of the *diisobutyrate* (VI), m. 73–4°; the *divalerate* (VII), yellow oil, b_1 210°, results in 70% yield; the *diisovalerate* (VIII), yellow oil, b_1 185°, results in 48% yield. III and Me_2SO_4 with KOH in a N atm., heated for 45 min. on the water bath, give 55% of the di-Me ether (IX), b_{18} 174–8°, m. 48–9° (Giral, *C. A.* **28**, 4053[4], gives m. 23–4°). Biol. assays on chicks gave the following vitamin K unit values: III 0.5 γ; III diacetate, II and IV 1 γ; V 1.25 γ; VI 5 γ; VII 1.25 γ; VIII 3 γ; IX 5 γ; data are also given for the time of duration of the curative effect of III, III diacetate, II and V. A discussion is given of the relationship between structure and vitamin K activity. C. J. West 5

Nor-α-phylloquinone (norvitamin K_1) and similar compounds. (Preliminary communication.) P. Karrer, A. Geiger, A. Rüegger and H. Salomon. *Helv. Chim. Acta* **22**, 1513–16(1939)(in German).—β-$C_{10}H_7CH_2CH_2MgBr$ reacts with 2,6,10-trimethyl-14-pentadecanone (I) to form a tertiary alc. (II), which is converted into the chloride, from which 1 mol. HCl is removed with pyridine. To the resulting β-phytylnaphthalene is added 1 Br mol. Oxidation of this dibromide yields a naphthoquinone deriv., which is debrominated with Zn, resulting in simultaneous reduction to the dihydronaphthoquinone deriv. Oxidation of this latter compd. gives nor-α-phylloquinone, 6

(III). The position of the double bond in III is indicated by the violet reaction with EtONa (K., *C. A.* **34**, 1308[8]). III is a viscous yellow oil, crystd. at lower temps. It con-

tains C 82.34, H 10.23% (calcd. for $C_{60}H_{44}O_2$: C 82.5, H 10.16%). Potentiometric titration with $Na_2S_2O_4$ (*C. A.* **33**, 8191[6]) gave a mol. wt. of 448 (calcd. 438). The absorption spectrum showed max. at 242, 248, 261, 265, 326 mμ. II may also be prepd. by condensation of Na β-naphthylacetylide with I, resulting in an unsatd. tertiary alc., which, upon reduction, gives II. Similar naphthoquinone derivs. are also obtained by direct condensation of 2-methyl-1,4-dihydroxynaphthalene with dihydrophytyl bromide in the presence of a catalyst and oxidation of the condensation product. The properties of 2′,3′-dihydro-α-phylloquinone are similar to those of the natural α-phylloquinone except for its failure to give a blue color with EtONa. It contains C 82.15, H 10.57% (calcd. C 82.2, H 10.69%). Ruth Berggren



Diene synthesis of 2,3-dialkyl-1,4-naphthoquinones related to vitamin K. Louis F. Fieser and Charlotte W. Wieghard. *J. Am. Chem. Soc.* **62**, 153-5(1940).—As a route to 2,3-dialkyl-1,4-naphthoquinones of high mol. wt. which might show vitamin K activity, a study has been made of the addn. of suitable dienes to α-naphthoquinone (I) and the partial dehydrogenation of the products. 1,1,3-Trimethylbutadiene and I give 60.5% of 1,1,3-trimethyl-1,4-dihydroquinone, m. 129-9.5° (Diels and Alder, *C. A.* **24**, 847, give 162°); this is inactive in the chick assay at a dosage of 200 γ. 1,1-Dimethyl-3-*tert*-butylbutadiene (b_{12} 58–9°) and I give 13% of the *addn. product*, $C_{20}H_{24}O_2$, m. 142–3°; passing air through the EtOH soln. contg. a little KOH gives 35% of *1,1-dimethyl-3-tert-butyl-1,4-dihydroanthraquinone*, yellow, m. 102-3°; with EtOH-KOH there results an intense-blue color changing slowly to yellow; it shows no vitamin K activity when assayed at 400 γ. The reaction between myrcene and I gives 64% of an addn. product, $C_{20}H_{32}O_2$, m. 61–1.3° (Arbuzov and Abramov, *C. A.* **29**, 1384[2], give 58–8.5°); heating with Ac_2O and C_5H_5N for 1 hr. gives 84% of the *hydroquinone diacetate*, needles with a fluorescent greenish tinge, m. 121-2°; cleavage with MeMgCl and oxidation with Ag_2O give 70% of *2-(δ-methyl-γ-pentenyl)1,4-dihydroanthraquinone*, yellow, m. 89.8–90.8°; EtOH-alkali gives a red color changing rapidly on shaking with air to pale-yellow; it showed no vitamin K activity when assayed at 50 γ. C. J. West

Use of hydrogen fluoride in acylations and cyclizations. Louis F. Fieser and E. B. Hershberg. *J. Am. Chem. Soc.* **62**, 49–53(1940); cf. *C. A.* **33**, 6295[8].—*peri*-Naphthane (10 g.), 6.1 g. Ac_2O, 5 cc. Et_2O and 200 g. HF, stirred 60 hrs. at room temp., give 71% of the *3-Ac deriv.*, b_2 170-5°; AcOH gives similar results; *trinitrobenzene deriv.*, yellow, m. 114–14.5° (all m. ps. cor.); oxidation with $Na_2Cr_2O_7$ in AcOH gives 4-aceto-1,8-naphthalic anhydride, m. 193–5°; KOCl gives *3-peri-naphthoic acid*, pale-yellow, m. 188.4–9°. Hydrindene, AcOH and HF (64 hrs. at room temp.) give 73% of the 5-Ac deriv., b_8 134–7°; BzCl and HF after 36 hrs. at room temp. give 75% of the 5-Bz deriv., b_8 203–4°; α-$C_{10}H_7OH$ and HF (72 hrs. at room temp.) give 90% of *5-(α-naphthoyl)hydrindene*, b_8 255–65°, m. 71–2°. Certain of the hydrocarbons which do not react at room temp. and atm. pressure can be acetylated in an Fe pressure vessel under reflux at temps. up to that of the steam bath. Acenaphthene (61.6 g.), 22 cc. Ac_2O and 120 g. HF, heated in the pressure vessel for 1.5 hrs. at a gage pressure of 4 atm., give 37% of the 1-Ac deriv. Catalytic reduction of 7.5 g. of 1-acenaphthoyl chloride in xylene (0.35 g. of 2% Pd-$BaSO_4$ and 0.075 cc. quinoline-S reagent) at 150–60° for 5.5 hrs. gives 72% of *1-acenaphthaldehyde*, very pale yellow, m. 99.5–100.5°. $C_{10}H_8$ and Ac_2O give a mixt. of α- and β-Ac derivs. somewhat richer in the β-isomer than that obtained by the Friedel-Crafts reaction. $C_{10}H_8$ does not react with succinic anhydride at moderate temps. and tar formation occurs on attempting to push the reaction. At 50–5° phenanthrene (I) and Ac_2O give a mixt. from which the 2- and 3-Ac derivs. were isolated. I and crotonic acid at 3 atm. pressure for 43 hrs. give an orange oil, b_2 215–25°, which appears to be a mixt. of isomeric methylketocyclopentenophenanthrenes. β-$C_{10}H_7MgBr$ and $C_6H_4(CO)_2O$ give 37% of *o*-(β-naphthoyl)benzoic acid, with 0.5 mol. C_6H_6, m. 129–31° and then 166–7°; reduction with Zn in NaOH gives 97% of *o*-(β-naphthylmethyl)benzoic acid, m. 139.5–40°, which with HF at room temp. for 1 hr., followed by MeMgCl, gives 14% of 9-methyl-1,2-benzanthracene, m. 136–7.5°; the *9-allyl analog*, pale yellow, m. 115–16°, results in 35% yield. 1-Methyl-7-bromonaphthalene forms a *trinitrobenzene deriv.*, yellow, m. 92.5–3°; *o*-(8-methyl-2-naphthylmethyl)benzoic acid with HF at room temp. for 7 min. gives *1′-methyl-2,3-benz-10-anthrone* (II), prisms or pale yellow needles, m. 175–6°; alc. alkali gives a purple color which fades on shaking with air; oxidation with CrO_3 in AcOH gives *1′-methyl-2,3-benzanthraquinone*, orange-yellow, m. 227–9°; it does not give a red color with $Na_2S_2O_4$ in alkali. II and MeMgCl give *1′,10-dimethyl-2,3-benzanthracene* (III), fiery red needles, m. 138–9°, on slow crystn. from abs. EtOH; rapid cooling gives bronze plates, m. 133° (bath temp.), solidifies and then m. 138–9°; concd. H_2SO_4 gives an olive-green color; *picrate*, purple-black, m. 164–5°; *trinitrobenzene complex*, purplish black, m. 166.5–7.5°. The ultraviolet absorption spectrum of III is given. C. J. West

Compounds of the diphensuccindene series. XVI. Several derivatives of 10-diphensuccindene-9,12-dione. Kurt Brand and Hans W. Stephan. *Ann.* **542**, 29–34 (1939); cf. *C. A.* **31**, 1394[8].—10-Bromodiphensuccindene-9,12-dione (3 g.), 2.5 g. $NH_2OH.HCl$ and 1 g. concd. HCl in 100 cc. EtOH, boiled 8 hrs., give 10-diphensuccindene-9,12-dione dioxime, dark violet-red, m. 273-3.5°, which is purified by pptn. from dil. NaOH with 30% of AcOH and by crystn. from AcOH. $PhNHNH_2.HCl$ similarly (but with boiling 40 hrs.) gives the *bis(phenylhydrazone)*, black to red-violet, m. 242° (decompn.); *bis(p-nitrophenylhydrazone)*, violet, m. 305.5° (from $PhNO_2$); the reaction is carried out in $PhNO_2$. Either 10-diphensuccindene-9,12-dione does not exist as such or the conditions for its prepn. have not been found. C. J. West

Further evidence on the Mills-Nixon effect. Warren C. Lothrop. *J. Am. Chem. Soc.* **62**, 132–3(1940).—The successful diazo coupling of 5-hydroxy-6-methylhydrindene (I) with *p*-$O_2NC_6H_4N_2X$ (*C. A.* **31**, 4311[1]) confirms the view that no quant. stabilization of 1 Kekulé form exists; with increasing alkali content (0.119 to 2.49 cc. *N* NaOH) the yield of product decreases from 35.9 to 0.5%. Data on coupling in buffered solns. indicate that the derivs. of hydrindene and tetralin are all inferior to β-$C_{10}H_7OH$ in coupling ability and are more comparable with 2,4-Me_2-C_6H_3OH. I with allyl bromide with K_2CO_3 in MeEtCO, refluxed 64 hrs., gives 98% of *5-alloxy-6-methylhydrindene*, b_3 95–7°; heating 0.97 g. of the ether and 2.75 g. $PhNMe_2$ at 215° for 1 hr. gives 0.83 g. (86%) of *4-allyl-5-hydroxy-6-methylhydrindene*, m. 43–5°. *5-Alloxy-4,7-dimethylhydrindene*, b_2 107–8°, nearly quant. yield; pyrolysis at 280° as above gives 75% of *5-hydroxy-6-allyl-4,7-dimethylhydrindene*, m. 66-7°; on standing in the air it turns a bright violet in 2 months. These results indicate that the Mills-Nixon effect is at the most qual. in the case of hydrindene. C. J. West

Mechanism of the reaction between phthalic anhydride and an amino diol. Murray M. Sprung. *J. Am. Chem. Soc.* **61**, 3381-5(1939).—From a consideration of polycondensation reactions, an amino alc. should give a linear polymeric ester-amide, whereas an amino diol should give a product having a 3-dimensional network structure analogous to that of glyceryl phthalate; this product, furthermore, should show the property of passing suddenly through the sol-gel transformation at a definite, crit. stage in the polycondensation reaction. The reactions of $Me_2C(NH_2)$-CH_2OH (I) with adipic acid (II) and of $H_2NCMe(CH_2OH)_2$ (III) with succinic (IV), maleic (V), II and sebacic acids (VI) gave results anticipated on the basis of these considerations. With I and II the product was a thermoplastic resin and apparently a linear polymer. In the latter cases, cross-linked resins were formed which were converted to insol., infusible materials when the combined esterification and amidation reactions had proceeded to the extent of about 65–75% of that theoretically possible. However when III was caused to react with *o*-$C_6H_4(CO)_2O$ (VII) it was found possible to carry the reaction to com-

pletion without observing the formation of a gel structure. The product obtained under these conditions was a colophony-like, brittle, amorphous solid, which appeared to be a mixt. of several ingredients. Heating VII and III at 135–45° for 2.5 hrs. causes no formation of H_2O; the acid value decreases from 444 to 223 and the product is a soft stringy, reddish resin which could not be crystd. or distd.; this appears to consist mainly of *N*-(1,1-dimethylolethyl)-phthalamic acid and the 1st step consists essentially in addn. of the NH_2 group of III to the anhydride linkage of VII; acyl halides reverse the reaction, giving VII and III. The 2nd step is ring closure and takes place when equimol. quantities of VII and III are heated at 150–200° for 2 hrs., 1 mol. of H_2O being split off; the product is a sticky, thermoplastic, resinous-appearing substance which could not be crystd., but 50% of it b_6 207–20°, giving a pale-red liquid, solidifying to a stiff balsam-like material; distn. at 50 microns (172–8°) gives a pale-yellow liquid which, after repeated crystn., m. 90.5–1° (*di-Bz deriv.*, m. 121.5°); it is believed that this is $C_6H_4(CO)_2NCMe(CH_2OH)_2$ (VIIa), although *o*-$C_6H_4CO.O.CH_2.CMe(CH_2OH).NH.CO$ is not excluded. The 3rd step is believed to be dehydration through the isoamide form of the ester-amide to yield an oxazoline; 50% of the colophony-like resin obtained on heating 3 moles VII and 2 moles of III b_2 195–205°; redistn. at very low pressure and crystn. from $C_2H_4Cl_2$ give 2 compds., $C_{12}H_{11}NO_4$,  (VIII), m. 160.5° and $C_{16}H_{17}NO_5$ (IX), m. 165–5.2°. VIII in abs. EtOH gives a *picrate*, 2VIII.$C_6H_3N_3O_{10}$, m. 225 6°; H_2O ppts. from the mother liquor the 1 1 *picrate*, m. 146–7°. VIII is hydrolyzed by Na in abs. EtOH; it could not be reduced by Zn in AcOH. IX does not form a picrate; Na and EtOH gives some $C_6H_4(CO)_2O$ and a compd. m. 227–8° (decompn.). Heating VIIA with excess VII at 170–200° for 20 min. gives some VIII. A table shows the H_2O formed (%) and the nature of the product on heating I and II or its di-Et ester and III with II, IV, V and VI.

C. J. West

Synthesis of phenanthrene derivatives. Alexander Schönberg and Frank L. Warren. *J. Chem. Soc.* **1939**, 1838–41.— The behavior of 2-Ph$C_6H_4CO_2H$ (I) with $SOCl_2$ and $(COCl)_2$ at various temps. is described. I and 1.6 mols. of $(COCl)_2$ in C_6H_6 at 30° for 1 hr. give the chloride, which is freed from HCl and $(COCl)_2$ by evapn. with Et_2O; added dropwise to CH_2N_2 in Et_2O, it yields 60% of *ω-diazo-o-phenylacetophenone* (II), yellow, m. 106°; the crystals change from yellow to red in a few weeks without losing their cryst. form. Aq. colloidal Ag (Ag_2O and $Na_2S_2O_4$ in H_2O) converts II into 86% of *o*-Ph$C_6H_4CH_2CO_2H$ (III). Refluxing 1.5 g. III, 5 cc. AcOH, 5 cc. Ac_2O and 0.2 g. $ZnCl_2$ for 3 hrs. gives 55% of the acetate, m. 76–7.5°, of 9-phenanthrol (IV) (over-all yield from I, 37%). This method is more satisfactory than direct ring closure with H_2SO_4. IV (0.55 g.) and 6 g. Zn, gently heated in H, give 72% of phenanthrene (V). Various attempts to eliminate the NH_2 group from 9-phenanthrylamine gave only traces of V. The Et ester of III and $(CO_2Et)_2$ with EtOK give Et *α*-keto-*β*-2-diphenylylsuccinate, a yellow liquid; with H_2SO_4 at 100° for 3 hrs. there results 63% of phenanthrene-9,10-dicarboxylic anhydride, m. 321–4° (over-all yield from I, 42%); the hot C_6H_6 soln. has a blue-green fluorescence.

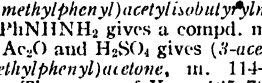
C. J. West

Preparation of dibenzopyrenequinone. I. The reaction of benzanthrone with benzoyl chloride. N. K. Moshchinskaya. *J. Gen. Chem.* (U. S. S. R.) **9**, 1376–9(1939).—In the condensation of benzanthrone and BzCl with excess of anhyd. $AlCl_3$ by the method of Scholl and Neumann (*C. A.* **16**, 2143), the poor yields of *dibenzopyrenequinone* (I) were traced to the contamination of the intermediate *1-benzoylbenzanthrone* (II) with the *2-isomer* (III). II, m. 197°, was sepd. from III, m. 205°, by repeated recrystn. of the reaction mixt., m. 162°, from PhCl. When treated with a mixt. of $AlCl_3$ and NaCl and O at 140° (cf. Vollmann, *et al.*, *C. A.* **32**, 145[9]), II was quantitatively converted into I, while III failed to react.

Chas. Blanc

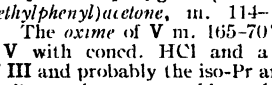
Decomposition of hexoses to hydroxymethylfurfural. A. D. Braun. *Biokhimiya* **4**, 276–82(1939).—The formation of hydroxymethylfurfural from ketohexoses is catalyzed by acids; from aldohexoses, by both acid and base.

H. Priestley



Attempted synthesis of morphenol. Alfred Burger and S. Avakian. *J. Am. Chem. Soc.* **62**, 226–7(1940).—4-Methoxydibenzofuran-1-carboxylic acid and $SOCl_2$ give 93% of the *acid chloride*, m. 162.5–3.5°; CH_2N_2 in Et_2O gives 86% of the *diazo ketone*, yellow, m. 150–1° (decompn.); NH_4OH in dioxane gives 75% of *4-methoxydibenzofuran-1-acetamide*, m. 203°; boiling with 20% EtOH-KOH for 3 hrs. gives 90% of the corresponding *acid*, m. 223–4°; treatment of the acid with concd. H_2SO_4, 85% H_2SO_4, HF at room temp., $SnCl_4$ in the cold and at the b. p. of the condensing agent, treatment of the acid chloride with $AlCl_3$ in ice-cold C_6H_6 or treatment of the acid bromide with $AlCl_3$ in $PhNO_2$ at room temp. and with boiling $SnCl_4$ did not yield a phenanthrene deriv.

C. J. West



Synthesis of 1,3-diphenyldihydroisobenzofurans, 1,3-diphenylisobenzofurans and *o*-dibenzoylbenzenes from the diene addition products to dibenzoylethylene. Roger Adams and Marvin H. Gold. *J. Am. Chem. Soc.* **62**, 56–61(1940); cf. *C. A.* **33**, 7808[4].—*cis*- or *trans*-$C_2H_2Bz_2$ (40 g.) and 35 g. crude 2,3-dimethylbutadiene in EtOH, refluxed 3 hrs., give 54% of *1,2-dimethyl-4,5-dibenzoylcyclohexene* (I), m. 111–11.5° (all m. ps. cor.); concd. H_2SO_4 gives a lemon-yellow color; *monodinitrophenylhydrazone*, orange, m. 226–8° (decompn.). I with Br in AcOH gives *1,2-dimethyl-1,2-dibromo-4,5-dibenzocyclohexane*, m. 170–1° (decompn.). I (5 g.) in 75 cc. Ac_2O and a little H_3PO_4, refluxed 10 min., gives 99% of *1,3-diphenyl-5,6-dimethyl-4,7-dihydroisobenzofuran* (II), yellowish green fluorescent crystals, m. 225–6°; org. solns. show a blue fluorescence and H_2SO_4 gives an orange-brown color. Br (5 cc.) in 30 cc. AcOH, added slowly to a boiling suspension of 15 g. (II) in 200 cc. AcOH, 30 g. AcONa and 15 cc. H_2O_2 gives 90% of *1,2-dimethyl-4,5-dibenzoylbenzene*, m. 143–4°; H_2SO_4 gives a violet color; oxidation with alk. $KMnO_4$ in dil. C_5H_5N yields 64% of *2-methyl-4,5-dibenzoylbenzoic acid* (III), m. 196–7°. Refluxing 3 g. III, 3 g. NaOH and 75 cc. 90% EtOH until the soln. turns a dark brownish red color (about 45 min.), adding 3 g. active Zn dust and refluxing 5–45 min. (depending upon the Zn) until the soln. is light yellow, then pouring the soln. into 70 cc. AcOH, give 97% of *1,3-diphenyl-5,6-dimethylisobenzofuran* (IV), orange-yellow, m. 187–8°; the org. solns. show a brilliant blue-green fluorescence; H_2SO_4 gives a reddish orange color. Illumination of IV in EtOH for a few days gives a quant. yield of III. II and Br in $CHCl_3$ give 38% (60% on unrecovered II) of *1,3-diphenyl-5,6-dibromo-5,6-dimethyl-4,5,6,7-tetrahydroisobenzofuran*, m. 155–6° (decompn.); refluxing in Ac_2O-AcOH-AcONa gives a mixt. of IV and III. IV and maleic anhydride in C_6H_6 give a quant. yield of *1,4-diphenyl-1,4-oxido-6,7-dimethyl-1,2,3,4-tetrahydronaphthalene-2,3-dicarboxylic anhydride* (V), m. 254–5° (decompn.); concd. H_2SO_4 gives a lemon-yellow color. Refluxing V in MeOH satd. with HCl for 2 hrs. (passing HCl through during this time) and the residue with NaOH in dil. EtOH for 4 hrs. gives 68% of *1,4-diphenyl-6,7-dimethyl-2,3-naphthalic anhydride*, m. 324–5° (decompn.); H_2SO_4 gives a greenish yellow color. With concd. H_2SO_4 at room temp. (3.5 hrs.) 0.5 g. V gives 0.2 g. of *6,7-dimethyl-1,2,3,4-dibenzoylenenaphthalene*, red, m. above 325°. II also adds maleic anhydride but the reaction is so readily reversible that the isolation of pure products was not accomplished. *trans*-$C_2H_2Bz_2$ and butadiene in C_6H_6, heated 2 hrs. at 100°, give a quant. yield of *4,5-dibenzoylcyclohexene*, m. 111.5–12°; *1,2-dibromo-4,5-dibenzoylcyclohexane*, m. 148–9° (90%); *1,3-diphenyl-4,7-dihydroisobenzofuran* (VI), yellowish green, m. 120–1° (99%); *1,3-diphenyl-5,6-dibromo-4,5,6,7-tetrahydroisobenzofuran* (VII), yellow, m. 150–1° (decompn.); it is relatively unstable; *o*-$C_6H_4Bz_2$ results in 85% yield and 1,3-diphenylisobenzofuran in 69% yield. VI and VII form

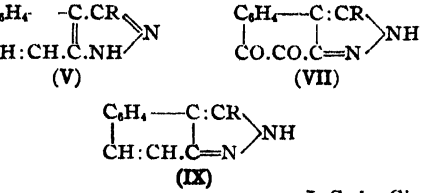
compds. with maleic anhydride but pure compds. could not be isolated because of the reversal of the reaction. *trans*-$C_2H_2Bz_2$ and cyclopentadiene give 89% of *2,3-dibenzoyl-1,4-endomethylene-1,2,3,4-tetrahydrobenzene* (VIII), m. 78–9°; the *cis*-isomer gives an isomer of VIII, m. 160–1°. These isomers could not be converted into furans by the above methods. C. J. West

Reaction between quinones and metallic enolates. X. Trimethylquinone and the enolates of β-diketones. Lee I. Smith and E. W. Kaiser. *J. Am. Chem. Soc.* **62**, 133–8 (1940); cf. *C. A.* **33**, 7790⁹.—This is a continuation of the work of S. and MacMullen (*C. A.* **30**, 3797⁹). Ac_2CH_2 (3.8 g.) in EtOH-EtONa (0.75 g.), cooled to 0°, treated during 12 hrs. with 2.25 g. trimethylquinone (I) in 30 cc. EtOH and the deep purple soln. decompd. with concd. HCl, gives 72% of *(3,6-dihydroxy-2,4,5-trimethylphenyl)acetylacetone* (II), m. 129–30°; $PhNHNH_2$ gives a compd. m. 205–6° (decompn.). Refluxing II with concd. HCl and a little EtOH for 3.5 hrs. gives 2,4,6,7-tetramethyl-5-hydroxycoumarone (III) (S. and M.), m. 138–9°; *Ac deriv.*, m. 91–2°. II with Ac_2O and H_2SO_4, 1 hr. at room temp., gives 81% of *(3,6-diacetoxy-2,4,5-trimethylphenyl)acetone* (IV), m. 135.5–6°; attempts to remove the Ac groups by acid or alkali either give unchanged IV or III. The *oxime* of IV m. 172.5° (decompn.). II with $(iso\text{-}PrCO)_2O$ and H_2SO_4 (7 hrs. at room temp.) gives 56% of *(3-isobutyroxy-6-acetoxy-2,4,5-trimethylphenyl)acetone*, m. 127.5–8°; $(ClCH_2CO)_2O$ gives 17.5% of the *3-chloroacetoxy analog*, m. 162–3°. I and the enolate of $Me_2CHCOCH_2Ac$ give 81% of *(3,6-dihydroxy-2,4,5-trimethylphenyl)acetylisobutylmethane* (V), m. 131.5–2.5°; $PhNHNH_2$ gives a compd. m. 167° (decompn.). V with Ac_2O and H_2SO_4 gives *(3-acetoxy-6-isobutyroxy-2,4,5-trimethylphenyl)acetone*, m. 114–15.5°; concd. HCl gives III. The *oxime* of V m. 165–70° (decompn.). Refluxing V with concd. HCl and a little EtOH gives a mixt. of III and probably the iso-Pr analog, which was not sepd. Pure substances could not be isolated from the reaction of $PrCOCH_2Ac$ or $BzCH_2Ac$ and only unchanged diketone was isolated when the enolate of Bz_2CH_2 was used. The acylation of II and V involves a rearrangement of 1 of the side-chain Ac groups from C to the *o*-O atom; simultaneously the other HO is acetylated by the reagent used. A mechanism is suggested for the rearrangement. I and $AcCHNaCO_2Et$ in EtOH (3.5 hrs. at room temp.) give a good yield of *3-acetyl-4,6,7-trimethyl-5-hydroxyisocoumaranone*, m. 126.5–8°; it does not yield a Me ether with Me_2SO_4 or CH_2N_2 and does not form an oxime; steam distn. gives

and

(cf. S. and M.). **XI. Duroquinone and the enolates of cyanoacetic ester and of β-diketones.** *Ibid.* 138–40.—The enolate of 5 g. of $NCCH_2CO_2Me$ and 6 g. of duroquinone (I) in C_6H_6 (refluxing 7 days) give 2.38 g. of *3-cyano-5,7,8-trimethyl-6-hydroxycoumarin* (II), yellow, m. 261.5–3°; Ac_2O and H_2SO_4 give the *6-Ac deriv.*, m. 227–8°. Heating II with 81% H_2SO_4 for 3.5 hrs. on the steam bath gives 60% of the *3-carbamido deriv.* (III), m. 302° (block, decompn.) or 288–90° (decompn.); *Ac deriv.*, m. 243–4.5°. III could not be converted to the acid but the known acid was converted to III through the acid chloride. The enolates of Ac_2CH_2 could not be condensed with I; the possible bearing of this fact upon the mechanism of I-enolate reactions is discussed. C. J. West

Argentine plants. I. Hypaphorine from Erythrina cristagalli. V. Deulofeu, E. Hug and P. Mazzocco. *J. Chem. Soc.* **1939**, 1841–2.—Seeds of *Erythrina cristagalli* (100 g.) were mixed with 10 g. $Ca(OH)_2$, dried and extd. with EtOH, the semisolid ppt. obtained on cooling was filtered off, the filtrate evapd. on the water bath and *N* HCl added; a yield of 1.86 g. of hypaphorine-HCl (tryptophan betaine-HCl), m. 234–5°, $[\alpha]_D^{20}$ 89.2° (H_2O, *c* 0.69), was obtained; nitrate, m. 220–2°; *flavianate*, orange-yellow needles or red rhombic prisms, m. 235° (decompn.). C. J. West



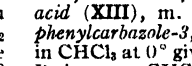
Ethanolamines of the oxindole series. Raymond B. Crawford and H. G. Lindwall. *J. Am. Chem. Soc.* **62**, 171–3(1940); cf. *C. A.* **30**, 5983⁴.—5-Nitroisatin (15 g.) in 15 cc. abs. EtOH and 10 g. of $MeNO_2$ at −15°, treated gradually with 15 drops of $EtNH_2$ with stirring and after 2 hrs. with 1 cc. AcOH, give 57% of *3-hydroxy-3-nitromethyl-5-nitrooxindole* (I), m. 145–7°; *1-Me deriv.*, m. 153° (82%); *1-Et deriv.*, m. 134–5° (72%). Reduction of 25.3 g. of I by suspension in 100 cc. concd. HCl and addn. of 41.6 g. Sn (temp. below 60°), followed in 0.5 hr. by 50 cc. concd. HCl and 41.6 g. Sn and boiling for 20 hrs., give 72% of *3-hydroxy-3-aminomethyl-5-aminooxindole* (II) (as *IICl salt*, m. above 300°); *picrate*, yellow, m. 198° (decompn.); *di-Bz deriv.*, m. 200–1°; *di(ethylcarbamido) deriv.*, m. 154°; *diurea deriv.*, chars without melting. *1-Me deriv.* of II: *di-HCl salt*, m. 170–3° (80%); *picrate*, yellow-brown, m. 201–3° (decompn.); *di-Bz deriv.*, m. 249–51°; *di(ethylcarbamido) deriv.*, m. 171–2°; *diurea deriv.*, m. 213–14°. *1-Et deriv.* of II: *di-HCl salt*, m. 137–7.5° (with 2 mols. H_2O, 40% yield); *picrate*, yellow, m. 179–80°; *di-Bz deriv.*, m. 227–7.5°; *di(ethylcarbamido) deriv.*, m. 183°; *diurea deriv.*, m. 224–5°. 7-Carbomethoxyisatin similarly gives *3-hydroxy-3-nitromethyl-7-carbomethoxyoxindole* (III), m. 159–61.5°; *1-Me deriv.*, m. 138–9° (80%); *1-Et deriv.*, m. 96–7.5° (60%). Reduction of III gives 80% of *3-hydroxy-3-aminomethyl-7-carboxyoxindole*, whose *HCl salt* m. 187–8°; *Bz deriv.*, m. 240–1.5° (53%); *ethylcarbamido deriv.*, m. 217–18° (45%); *urea deriv.*, m. 218–19° (42%). C. J. West

Natural hydroxy- and methoxyanthraquinones, and some new syntheses in the anthraquinone series. R. Eder and B. Siegfried. *Pharm. Acta Helv.* **14**, 34–7 (1939).—A tabulated list is given of 72 anthraquinones occurring in nature, with data on compn., m. p., color, occurrence and references. Their chem. relations and practical uses are discussed. Four new hydroxymethylanthraquinone derivs. were prepd. and their structural compn. detd. They are: (*a*) *1-hydroxy-5-nitro-4-methyl-A* (*A* = anthraquinone), m. 236.5–237° (corr.) (decompn.); (*b*) *1,5-dihydroxy-4-methyl-A*, m. 234–234.5° (corr.); (*c*) *1,8-dihydroxy-4-methyl-A*, m. 211–212° (corr.); (*d*) *1,8-dihydroxy-2-methyl-A*, m. 176.5–177° (corr.); *b*, *c* and *d* are isomers of chrysophanol. None of compds. *a*–*d* was as yet found in nature. The prepn. of *a*–*d*, starting with the condensation of 3-nitrophthalic anhydride with *o*- and *p*-cresol in presence of $AlCl_3$ or H_3BO_3, is given in detail. S. Waldbott

2-Aminophenylanthraquinone and 1,2-phthaloylcarbazole. P. H. Groggins. *Ind. Eng. Chem.* **32**, 98(1940); cf. *C. A.* **24**, 3772.—The previously reported amino deriv. obtained by the ammonolysis of 2′-chloro-β-phenylanthraquinone is not 2′-amino-β-phenylanthraquinone, but 1,2-phthaloylcarbazole, orange needles, m. 255°, from toluene and *o*-$C_6H_4Cl_2$, obviously resulting from a ring closure between the NH_2 group and the 1-position of the anthraquinone nucleus, probably by the oxidizing influence of the $PhNO_2$ used in the reaction. The m. p. corresponds to that of the product derived by heating 1-α-anthraquinonylbenzotriazole in Ph_2NH. It dissolves in concd. H_2SO_4 with a deep blue color and shows an instantaneous color change when a drop of HNO_3 is added to the soln., a reaction characteristic of the carbazole structure. John F. Lontz

A new case of the dehydrogenating action of thionyl chloride. A. Corbellini. *Atti X° congr. intern. chim.* **3**, 82–9(1939).—$SOCl_2$ (I), on reaction with *cis-o-[4,5-(1′,2′-naphtho)-3-pyrazolyl]cinnamic acid* (II), not only chlorinates it but dehydrogenates it as well. The resulting acid chloride with H_2O, MeOH, or EtOH gives the acid (III) or the corresponding Me and Et esters (IV), all yellowish orange and definitely different from II or its esters, all colorless. III is readily hydrogenated to II. II with $KMnO_4$ in alk. soln. gives V (R = *o*-$OHCC_6H_4$-) which then goes over to the acid (VI). VI is also obtained from IV by treating the latter with $KMnO_4$ in C_5H_5N. Oxi-

dation of IV with CrO_3 gives VII (R = *o*-$RO_2CC{:}CC_6H_4$-) (VII) which on further oxidation with $KMnO_4$ in KOH gives (*o*-$HO_2CC_6H_4CO)_2$. IV with NH_2NH_2 gives VIII (V, R = *o*-$CH{:}C(OH).NH.N{:}CC_6H_4$-). Apparently III must be *o*-[*4,5-(1',2'-naphtho)-3-pyrazolyl*]*phenylpropiolic acid*, with the structure IX (R = *o*-$HO_2CC{:}CC_6H_4$-).



(V) (VII)

J. C. Lo Cicero

Attempts to prepare optically active trivalent nitrogen compounds. I. Syntheses of 1,9-phenylenecarbazole and derivatives. Helen G. Dunlop and S. Horwood Tucker. *J. Chem. Soc.* **1939**, 1945–56.—Carbazole (I) (20 g.), 40 g. *o*-$ClC_6H_4NO_2$, 20 g. K_2CO_3 and 0.2–0.3 g. Cu bronze, boiled for 3 hrs., give 50–60% of 9-(2'-nitrophenyl)carbazole (II), yellow, m. 156° (cor.); without Cu the yield is 10% (Nelmes and Tucker, *C. A.* **28**, 766[9]); replacement of K_2CO_3 by 1 g. Cu bronze gives an unworkable tarry product; after 2 hrs. much I is recovered; after 4 hrs. the product is tarry. Boiling 10 g. II, 40 g. $SnCl_2$ and 150 cc. AcOH, satd. with HCl, and pouring into a large excess of hot, fairly concd. NaOH give 75% of *9-(2'-aminophenyl)carbazole* (III), m. 119–21° (cor.); Sn and HCl in AcOH give 50% III. III (5 g.) in 50 cc. glacial AcOH and 11 cc. H_2SO_4, diazotized at 0° with 1.35 g. $NaNO_2$ in 30 cc. H_2O and boiled 0.5 hr., gives 56% of *1,9-phenylenecarbazole* (IV), m. 136.5–8.5° (cor.), sublimes at 250° and 15 mm.; the use of excess $NaNO_2$ gives a lower yield; *picrate*, red, m. 165–9°; *sym-trinitrobenzene complex*, yellow, m. 192–4°. In the synthesis of IV replacement of the AcOH by MeOH gives 9-phenylcarbazole (V); when the diazonium sulfate from III is treated with NaOH an unworkable product is obtained; $AlCl_3$ in various solvents has no effect on V. Heating 5 g. I, 12 g. PhI, 5 g. of K_2CO_3 and 0.3 g. Cu bronze at 190–200° for 6 hrs. gives 65% V, m. 91–5°; *picrate*, scarlet, m. 126–9°; *sym-*$C_6H_3(NO_2)_3$ *complex*, orange, m. 132–4°. I and 4,3-$Cl(O_2N)C_6H_3Me$ with K_2CO_3 and Cu bronze at 220–30° for 3 hrs. give 35% of *9-(2'-nitro-4'-methylphenyl)carbazole*, yellow, m. 104–6°; no condensation occurs with $BaCO_3$; reduction as above gives 75% of the *2'-*NH_2 *deriv.*, m. 117–19°; through the diazo reaction there results *1,9-(4'-methylphenylene)carbazole*, m. 109–11° (cor.), sublimes at 210–70° and 15 mm.; org. solns. have a faint violet fluorescence; *picrate*, red, m. 145–50°; *sym-*$C_6H_3(NO_2)_3$ *complex*, yellow, m. 170–2°. I and *p*-IC_6H_4Me give 66% of *9-p-tolylcarbazole*, m. 105–7°; *sym-*$C_6H_3(NO_2)_3$ *complex*, red (yellow when powd.), m. 106–8°; fusion with KOH effects neither ring closure nor oxidation of the Me to the CO_2H group. I, 1,4,2-$Cl_2C_6H_3NO_2$, K_2CO_3 and Cu bronze at 220–30° for 4 hrs. give 35% of *9-(4'-chloro-2'-nitrophenyl)carbazole*, orange-yellow, m. 134–6°; *2'-*NH_2 *deriv.*, m. 84–6° (80% yield); the diazo reaction gives a black tar; sublimation at 230–50° at 15 mm. gives a yellowish compd., m. 138–40°. I and *p*-ClC_6H_4I with Cu bronze give 70% of 9-(4'-chlorophenyl)-carbazole, m. 140–3°; without Cu the yield is 17%. Boiling 9-(2',4'-dinitrophenyl)carbazole (VI) with Na_2S and S in MeOH for 2 hrs. gives the *4'-*NH_2 *deriv.*, red, m. 164–6° (*Ac deriv.*, m. 261–3°); the diazo compd., poured into EtOH, gives II; reduction of VI with $SnCl_2$ and AcOH-HCl gives 63% of *9-(2',4'-diaminophenyl)carbazole*, m. 128–30°; *di-Ac deriv.*, m. 230–5°. 9-(2'-Nitro-4'-acetamidophenyl)carbazole is reduced by $SnCl_2$ in AcOH-HCl to the 2'-NH_2 deriv., m. 235–45° (75% yield); attempts to effect ring closure by the diazo reaction failed. I could not be condensed with 4,3-$Cl(O_2N)C_6H_3Ac$, 4,3-$Br(O_2N)C_6H_3Ac$ or 4,3-$I(O_2N)C_6H_3Ac$. *p*-IC_6H_4Ac gives the *3-*NO_2 *deriv.*, pale yellow, m. 112–15°. Heating 10 g. I, 25 g. 4,3-$Cl(O_2N)C_6H_3CN$ and 10 g. K_2CO_3 at 180–90° for 12 hrs. gives 40% of *9-(2'-nitro-4'-cyanophenyl)-carbazole*, yellow, m. 172–4°; no condensation occurs with $BaCO_3$; above 200° or after 18 hrs. a charred mass results; reduction gives 70% of the *2'-*NH_2 *deriv.*, m. 186–8° (*Ac deriv.*, m. 241–3°); boiling the amine (4.2 g.) in 30 cc. AcOH and 75 cc. concd. HCl for 1 hr. gives a quant. yield of crude 9-(2'-amino-4'-carboxyphenyl)carbazole-HCl (VII), m. 210–20°; the ordinary diazo method of ring closure not being successful, it was modified by adding $PhNO_2$, which gives 18% of *1,9-phenylenecarbazole-4'-carboxylic acid* (VIII), pink, m. 340° (*Me ester*, pink, m. 155–62°); heating VII with Cu bronze gives IV; it was not decarboxylated with Cu in boiling quinoline or with Cu at 300°. The diazo compd. from VII in MeOH-concd. H_2SO_4 on boiling gives 9-(4'-cyanophenyl)carbazole, m. 175–7°. I, *p*-$IC_6H_4CO_2Et$, K_2CO_3 and Cu bronze, heated 6 hrs. at 220–30°, give 80% of the *Et ester*, m. 97–100°, of *9-phenylcarbazole-4'-carboxylic acid*, m. 215–19°; decarboxylation yields V. I (4.2 g.), 3 cc. Cl_3CCN, 4 g. $AlCl_3$ and 40 cc. PhCl, satd. with HCl, heated from 40 to 100° in 1 hr. and maintained at 100° for 1 hr., followed by hydrolysis with concd. HCl, give 84% of *3-trichloroacetylcarbazole* (IX), yellow, m. 206–8°; *Ac deriv.*, cream, m. 120–5°; warming IX with NaOH gives $CHCl_3$ and carbazole-3-carboxylic acid, m. 270°; the acid seps. with 1 mol. of AcOH of crystn.; from crude IX the yield of acid is 92%; Et ester (X), m. 165–7°; Et carbazole-9-carboxylate could not be converted into the 3-isomer by $AlCl_3$ in $PhNO_2$. X, *o*-$ClC_6H_4NO_2$, K_2CO_3 and Cu bronze, 5 hrs. at 200–10°, give 60% of *Et 9-(2'-nitrophenyl)carbazole-3-carboxylate*, yellow, m. 120–2°; reduction gives 70% of the *2'-*NH_2 *deriv.*, m. 140–2°; the diazo reaction gives *1,9-phenylenecarbazole-3-carboxylic acid* (XI), m. 305°; XI also results by passing dry HCl into a soln. of 2 g. IV, 1 cc. Cl_3CCN and 4 g. $AlCl_3$ in 5 cc. PhCl and allowing it to stand 3 weeks. Heating 4.2 g. I, 6 cc. Cl_3CCN and 8 g. $AlCl_3$ in 40 cc. PhCl for 1 hr. at 40 to 100° and 1 hr. at 100° and hydrolyzing with concd. HCl give 44% of *carbazole-3,6-dicarboxylic acid*, pale green, does not m. 360°; it is purified by boiling a soln. in C_5H_5N with 10–20 vols. AcOH and adding H_2O to produce a turbidity; *Et ester* (XII), pale yellow, m. 206–7°. XII, *o*-$ClC_6H_4NO_2$, K_2CO_3 and Cu bronze, heated 5 hrs. at 180°, give 70% of *Et 9-(2'-nitrophenyl)carbazole-3,6-dicarboxylate*, pale yellow, m. 202–3°; reduction gives 80% of the *2'-*NH_2 *deriv.*, m. 175–7°; the diazo reaction yields 46% of the *Et ester*, m. 185–7°, of *1,9-phenylenecarbazole-3,6-dicarboxylic acid* (XIII), m. above 360°. XII and PhI give *Et 9-phenylcarbazole-3,6-dicarboxylate*, m. 139–41°. IV and Br in $CHCl_3$ at 0° give the *3(?)-Br deriv.*, m. 205–10°; excess Br in warm $CHCl_3$ gives a *3,6(?)-di-Br deriv.*, m. 202–9°; addn. of HNO_3 to a boiling soln. of IV and I in AcOH gives an *iodotrinitro deriv.*, red, does not m. 340°. Heating I, BzCl and K_2CO_3 at 140–60° for 1 hr. gives 60% of the 9-Bz deriv. VIII was not prepd. in sufficient amt. for resolution expts.; XIII gives salts with brucine, quinine, morphine and ephedrine but dissocs. on attempted recrystn. and the recovered acid is inactive. C. J. West

Synthesis of the alkaloid pilosinine. A. M. Polyakova, V. A. Preobrazhenskiĭ and N. A. Preobrazhenskiĭ. *J. Gen. Chem.* (U. S. S. R.) **9**, 1402–9(1939).—Pyman (*C. A.* **7**, 978) isolated from *Pilocarpus microphyllus* 0.007% of the alkaloid pilosine (carpiline), $C_{16}H_{18}O_2^3N_2$, which when distd. with 20% KOH was decompd. into BzH and an optically active base, named by him *pilosinine* (I) and identified as  In the first synthesis of I here described Et succinate and HCO_2Et are with MeONa condensed at 20° to *Et formylsuccinate;* the free ester is reduced with Al-Hg and then distd. to give CO_2 and *Et pilosininate*,  b_{19} 154°, b. 273–6°; the latter on sapon. with dil. HCl gave the *free acid*, m. 64–5°, b_{10} 203°; its *chloride* (prepd. by heating with excess $SOCl_2$ at 50–60° for 5 hrs.), $b_{1.2}$ 107°, when treated

with 3 mols. CH_3N_3 in Et_2O at 0° formed *diazomethyl pilosinyl ketone*, $CH_2.O.CO.CH_2.CHCH_2COCHN_2$; the reaction mixt. directly introduced into 87 ml. of abs. alc. contg. 2.06 g. Ag_2O and heated at 80° yielded 70.7% *Et homopilosininate*, $CH_2.O.OC.CH_2.CHCH_2CO_2Et$, b_{15} 161°, n_D^{25} 1.456, M. R.$_D$ 40.31; the *free acid*, m. 86.5–7.5°, b_1 168°; its *chloride*, $b_{0.2}$ 126°, treated with CH_3N_3 gave *diazomethyl homopilosinyl ketone* (II); this, treated with glacial AcOH at 75°, afforded 84% *acetoxymethyl homopilosinyl ketone*, $b_{0.8}$ 168°; 4.49 g. of the ketone in 50 ml. H_2O is treated with 9 g. $Cu(OAc)_2$, 4 ml. of 40% CH_2O and 90 ml. of 25% NH_4OH at 100° for 1 hr., the Cu is removed with H_2S and the excess H_2S with N, the acidified reaction mixt. is vacuum-distd. to expel HCl, the residue is extd. with Et_2O, dissolved in the min. amt. of H_2O, alkalized with NH_4OH, extd. with $CHCl_3$, dried with Na_2SO_4 and the $CHCl_3$ distd. off *in vacuo*, giving *pilosinidine* (*HNO$_3$ salt*, m. 117–18°); pilosinidine (1 g.) is treated with 2 ml. MeOH and 0.9 g. MeI in a sealed tube at 50–60° for 2 hrs., the excess of MeOH and MeI is distd. off *in vacuo* at 30–40°, the residue in 5 ml. H_2O is made strongly alk. with 10 ml. of satd. K_2CO_3, the soln. is extd. with $CHCl_3$ and the $CHCl_3$ is expelled *in vacuo* at 25–30°, giving 70% I (*nitrate*, m. 158.5–60° (abs. alc.)). I is an oil, sol. in H_2O, alc., Me_2CO and poorly sol. in dry Et_2O. In the modified procedure II in dry ether is treated with gaseous HCl at 0° for 1 hr. and the ether vacuum-distd., giving 67% *chloromethyl homopilosinyl ketone*, $b_{0.7}$ 163°; 1.2 g. of the ketone in 10.5 ml. of abs. alc. and 1.45 g. $C_6H_4(CO)_2NK$ is refluxed 8 hrs. and the resulting phthalimide deriv. is decompd. with 20 ml. of 50% HCl by boiling 8 hrs., forming 90% *aminomethyl homopilosinyl ketone* (*HCl salt*, m. 140–3°); refluxing 0.95 g. of the ketone with 0.56 g. KSCN in 2 ml. H_2O for 8 hrs. yielded 74% pilosinidine-2-thiol, m. 202.5–3°; oxidation with $FeCl_3$ in H_2O gave pilosinidine. Chas. Blanc

Action of formamide on aryl acyloins. Formation of diarylglyoxalines and tetraarylpyrazines. Armando Novelli. *Anales asoc. quím. argentina* **27**, 161–8(1939).—As shown by Ingersoll and collaborators (*C. A.* **30**, 7550[2]) the active agent in the formation of primary amines from ketones heated with HCO_2NH_4 is $HCONH_2$, formed by dehydration of the salt. N. has extended the method to the synthesis of secondary and tertiary amines (*C. A.* **33**, 2493[6]). Benzoin with excess of $HCONH_2$ does not react normally but gives chiefly 4,5-diphenylglyoxaline (I), with a little tetraphenyl-*p*-diazine (amarone) (II). This reaction appears to be general for aromatic acyloins. From benzoin with HCO_2NH_4 at 230°, Leuckart (*J. prakt. Chem.* **41**, 330(1890)) obtained II almost quantitatively, with small amts. of BzH and 2,4,5-triphenylglyoxaline (lophine) (III) as by-products, and Davidson, Weiss and Jelling (*C. A.* **32**, 1702[4]), in the presence of excess of Ac_2O, obtained 36% I and *N*-desylformamide, $HCONHCHPhBz$ (IV). N. has tried the reaction with benzoin, anisoin, benzanisoin and *p*-toluoin, and in all cases obtained the corresponding analogs of I and II; analogs of III and IV were never found. HCO_2H (11.50 g.) and 11.50 g. $(NH_4)_2CO_3$ were heated at 165° in a distg. flask until no more water distd. over, allowed to cool, treated with 4.20 g. powd. benzoin, heated very slowly to 180–5° and kept 2 hrs. at that temp. At 120–50° there appeared an intense orange-red color (pointing to the intermediate formation of a dihydro deriv. of II), finally changing to a light yellow. The cooled product was powd., treated with 50 cc. boiling water, filtered, dried (yield, 4.30 g.), boiled 10 min. with 50 cc. of 10% HCl and filtered hot, and the treatment was repeated. The yellow insol. residue (0.45 g.), dissolved in a little boiling benzene and pptd. with 3–4 vols. petr. ether, yielded needles, m. 246–7°, giving an intense red color with concd. H_2SO_4 and identified as II by mixed m. p. with a sample prepd. according to D., W. and J.; yield, 10%. The acid filtrates, decolorized with C, pptd. with NH_3 and crystd. from dil. alc. or pyridine, yielded 75% I, m. 227–8° (mixed m. p.). Similarly anisoin gave 10% *tetra-p-methoxyphenylpyrazine*, m. 282–3°, giving an intense violet color with H_2SO_4, and 70% *4,5-di-p-methoxyphenylglyoxaline*, m. 183–4°. Benzanisoin, prepd. according to Jenkins (*C. A.* **26**, 2451), yielded *diphenyldi-p-methoxyphenylpyrazine*, m. 183–4°, giving a red-violet color with H_2SO_4, and *p*(or *5*)*-phenyl-5*(or *4*)*-p-methoxyphenylglyoxaline*, m. 214–15°. *p*-Toluoin (Gattermann, *Ann.* **347**, 364 (1906)) gave 8% *tetra-p-tolylpyrazine*, m. 295–6°, giving an intense red-violet color with H_2SO_4, and 75% *4,5-di-p-tolylglyoxaline*, m. 275–6°. The following reaction mechanism is suggested. There is first formed an unstable addn. product, $HCONHCPh(OH)CH(OH)Ph$, which loses water to form $HCONHCPh{:}C(OH)Ph$ or the tautomeric form, $HCONHCHPhCOPh$; this is then converted into the formylamine, $HCONHCPh{:}C(NHCOH)Ph$ (V), which by loss of HCO_2H yields I. V reacts in part with unchanged benzoin to form the dihydropyrazine, $PhC.NH.CPh$ ‖ $PhC.NH.CPh$, which is dehydrogenated to II.

C. A. R.

Triazolium salts. IV. Reduction of benzotriazolium salts. F. Krollpfeiffer, W. Graulich and A. Rosenberg. *Ann.* **542**, 1–13(1939); cf. *C. A.* **29**, 2165[9].—Attempts to increase the yield of *o*-$MeNHC_6H_4N.NMe$ (I) from the reduction of 1,2-dimethylbenzotriazole-Me_2SO_4 (II) (part III) were unsuccessful. The use of concd. NaOH gives 1-methylbenzotriazole (III). II (20 g.) gives 3.1 g. of I and 3.4 g. of the yellow oil $C_8H_{11}N_3$ (IV), b_1 108–10°. IV with Ac_2O and AcONa gives a *di-Ac deriv.*, m. 135–6°; partial hydrolysis with EtOH-NaOH gives the *mono-Ac deriv.*, m. 92–3°, which with Ac_2O regenerates the di-Ac deriv. I (10 g.) in 200 cc. 2 *N* AcONa, treated with 40 g. of $Na_2S_2O_4$ and boiled 5 min., gives 3.5 g. of $H_2NC_6H_4NHMe$, b_{13} 131–3°, identified by transformation into III through the diazo reaction. I yields a *mono-Ac deriv.*, pale yellow, m. 193–4°. HCl ppts. from an Et_2O soln. of I a deep violet HCl salt, which quickly becomes colorless; the very hygroscopic salt cannot be recrystd. without decompn. Boiling an EtOH soln. of the salt 10 min. gives NH_4Cl and 1-methylbenzimidazole (V); a similar result is obtained by heating I in EtOH. When the HCl salt from 6.2 g. I is added to 400 cc. ice water, there results 0.25 g. of a *compd.*, $C_{18}H_{16}N_6$, m. 275° (decompn.), not investigated further. If the aq. soln. is made alk. with NaOH (cooling) and extd. with Et_2O, there is recovered 4.1 g. of a reddish brown oil, b_1 112–25° (25.3% *N*); on warming to 60–70° NH_3 is formed; the undistd. product in Et_2O gives with HCl a dirty violet HCl salt; rubbing with EtOH gives at times only V.HCl and in other cases a yellow HCl salt, m. 154–5°; fractionation of the latter with MeOH-picric acid gives V picrate and an orange picrate (VI), decomps. 135–6°. Heating the Ac deriv. of I with 20 parts of 2 *N* HCl for 20 min. gives V (isolated as the picrate); reduction of the Ac deriv. yields 73% of 1,2-dimethylbenzimidazole. Attempts to rearrange I by heating either gave unchanged I or caused decompn. without the formation of characteristic compds. Boiling I with 2% EtONa in EtOH for 1.5 hrs. gives a compd., $C_8H_9N_3$, b_3 150–60°, decomps. about 120°; its picrate is the same as VI; Ac_2O gives the *Ac deriv.*, $C_{10}H_{11}N_3O$, m. 120–1°, and a small quantity of a compd. decompg. about 310°. IV gives with HCl a violet color (not as deep as that of I), changing to white in a short time; the HCl salt from 8.25 g. IV on boiling with EtOH gives 0.35 g. NH_4Cl and 4.8 g. of an oil, b_1 96–104° and partially solidifying (V). Reaction of 1 g. of IV with MeOH-picric acid gives 2 g. of V picrate. Heating 7.5 g. of the di-Ac deriv. of IV with 180 cc. 2 *N* HCl for 20 min. gives about 1 g. of an insol. resin; the other products are 0.3 g. of 3-methyl-5,6-benzo-1,2,4-triazine (m. 95–6°) and V (1.3 g. of picrate). Although not definitely proved, IV is believed to be *o*-$MeNHC_6H_4NHN{:}CH_2$. III and Me_2SO_4 give 1,3-dimethylbenzotriazole-Me_2SO_4 (VII), hygroscopic, m. 97–8°; VII absorbs moisture from the air so that the salt melts in the hand. Some II is present in crude VII (formation of 0.9 g. of I on reduction of 30 g. salt). VII is not reduced by $Na_2S_2O_4$ in the presence of AcONa. Reduction of 26 g. VII in 150 cc. 2 *N* HCl with Zn (addn. of some concd. HCl) gives 11 g. of *o*-$C_6H_4(N$-

$Me_2)_2$, m. 27.5–8.5°. On heating 3 g. VII in 90 cc. concd. NaOH and 120 cc. H_2O there results 17.5 g. of *o*-methylamino-α-methylphenylhydrazine (VIII), yellow viscous oil, b_{14} 142–3°; HCl ppts. from a C_6H_6 soln. a hygroscopic HCl salt. VIII and Ac_2O give 1,2,3-trimethyl-2-hydroxydihydrobenzimidazole; BzH in AcOH gives 1,3-dimethyl-2-phenyldihydrobenzimidazole. Reduction of VIII with Zn in HCl gives *o*-$C_6H_4(NMe_2)$. Heating VIII with 2 *N* HCl gives *N*-tetramethyldiaminophenazonium chloride, m. 190–5°. C. J. West

The reduction of 1,2,3-benzotriazole and its *N*-methyl derivatives by sodium in liquid ammonia. Norman O. Cappel and W. Conard Fernelius. *J. Org. Chem.* **5**, 40–7 (1940).—When 1,2,3-benzotriazole (I) is treated in liquid NH_3 with Na, no H is evolved and equimol. amts. of Na salts of I (II) and of dihydrobenzotriazole (III) are formed. This mixt., II and the Na salt of 1- and 2-methylbenzotriazole (IV and V) are not affected by a Na soln. The active H from the interaction of Na and the NH_4 ion, $(NH_4^+ + \epsilon^- \rightarrow NH_3 + H)$ reduces II and V to *o*-$C_6H_4(NH_2)_2$ but not III. Active H reduces IV to *o*-$H_2NC_6H_4NHMe$ (VI). In basic solns. where the H is generated by the interaction of K in liquid NH_3 in the presence of Fe

$(K \rightleftharpoons K^+ + \epsilon^-;\ NH_3 + \epsilon^- \rightarrow NH_2^- + H)$ the H is relatively ineffective in reducing the K salt of I to *o*-$C_6H_4(NH_2)_2$. The latter is identified as its *dibenzo[a,c]phenazine*, m. 204–6°, its *dibenzenesulfonyl derw.*, m. 190–1.5°, and di-Bz deriv., m. 305°. The *di-Bz deriv.* of VI m. 152.8–3.8°, the *dibenzenesulfonyl deriv.* m. 156–7°. The bearing of these results on the general subject of reductions in liquid NH_3 is discussed. F. E. Brauns

Chemistry of vitamin E. XX. Preparation of *o*-xylohydroquinone. Oliver H. Emerson and Lee Irvin Smith. *J. Am. Chem. Soc.* **62**, 141–2(1940); cf. *C. A.* **34**, 4289.—Details are given of the nitration of *o*-xylene (85% of the 3-NO_2 deriv.), the reduction to the 3-NH_2 deriv. (74%) and its oxidation to *o*-xyloquinone (33%) or an over-all yield of 21%; refluxing with Zn in dil. AcOH gives 95% of *o*-xylohydroquinone. **XXI. Dealkylation of hydroquinone ethers related to the tocopherols.** Lee Irvin Smith, Herbert E. Ungnade and Willa B. Irwin. *Ibid.* 142–4; cf. *C. A.* **33**, 7787.—1-(3,6-Dimethoxy-2,4,5-trimethylphenyl)butan-3-one and MeMgI give the corresponding 3-methylbutan-3-ol (I), an oil (*3,5-dinitrobenzoate* (II), light yellow, m. 148–8.5°). 2,2,5,7,8-Pentamethyl-6-hydroxychroman (III) and AcOAg in MeOH, refluxed 1 hr., give a quinone (IV), reductive methylation of which gives I, characterized as II. I can be cleaved by heating with excess MeMgI at 180° for 45 min., giving the hydroquinone (corresponding to IV) as a yellow oil; air oxidation yields IV: the tri-Ac deriv., from reductive acetylation could not be crystd.; HNO_3 in EtOH gives the red color of the *o*-quinone; since I does not give this reaction, it indicates that considerable demethylation of I had occurred. These reactions establish the structure of I and III and show that when the Grignard reagent reacts with dihydrocoumarins the products are 2,2-dialkylchromans. **XXII. Reaction between Grignard reagents and coumarins and hydrocoumarins.** Lee Irvin Smith and P. M. Ruoff. *Ibid.* 145–8; cf. *C. A.* **33**, 7791.—Coumarin (I) (25 g.), added during 2 hrs. to about 2 moles of EtMgBr in Et_2O at room temp. and then refluxed 1 hr., gives 20 g. of *diethyl-o-hydroxystyrylcarbinol* (II), m. 67–8°; concd. H_2SO_4 gives a deep red and $FeCl_3$ an olive-green color. Reduction gives 1-*o*-hydroxyphenyl-3-ethyl-3-pentanol, m. 74–5°, previously obtained from the dihydro deriv. of I and EtMgBr. Refluxing 4 g. II in 20 cc. AcOH for 1 hr. and distn., with repetition of the action of AcOH gives about 1 g. of *2,2-diethyl-3-chromene* (III), b_{14} 125–6°; H_2SO_4 gives a bright red color. Similarly I and MeMgI give the *di-Me analog* of II, m. 53–5°, which is cyclized to the *di-Me analog* of III, b_{18} 96–7°; *di-Bu analog* of III, b_{16} 164–5°, n_D^{25} 1.5220 (the analog of II was not isolated). The dihydro deriv. of I and BuMgBr give *1-o-hydroxyphenyl-3-butyl-3-heptanol*, m. 67–8.5°; AcOH-H_2SO_4 gives *2,2-dibutylchroman*, pale-yellow, b_8 165–8°, n_D^{25} 1.5097. In the prepn. of III and its analogs, there is also formed a large quantity of dark viscous oil, probably contg. polymeric substances. C. J. West

Synthesis of 5-hydroxy-8-methoxyflavone (primetin monomethyl ether). Wilson Baker, N. C. Brown and J. A. Scott. *J. Chem. Soc.* 1939, 1922–7; cf. *C. A.* **33**, 6844.—2,6-$(HO)_2C_6H_3Ac$ (60 g.), 300 cc. Me_2CO, 70 g. $PhCH_2Cl$ and 120 g. K_2CO_3, refluxed 3 hrs., 40 g. K_2CO_3 added and the refluxing continued for 6 hrs., give 55 g. of *2-hydroxy-6-benzyloxyacetophenone* (I), m. 109–10°; Et-OH-$FeCl_3$ gives a violet color; a small amt. of *2,6-dibenzyloxyacetophenone*, m. 71.5°, is also formed. I (24.2 g.) in 200 cc. H_2O contg. 20 g. NaOH, treated dropwise with 29.7 g. of $K_2S_2O_8$ in 600 cc. H_2O during 4 hrs. at 15–20° and allowed to stand 24 hrs., give on acidification 10 g. unchanged I; extn. of the filtrate with Et_2O and heating the aq. layer with 100 cc. concd. HCl and 300 cc. Et_2O give 85% of *2,5-dihydroxy-6-benzyloxyacetophenone* (II), yellow, m. 94°; NaOH gives a bright yellow color and $FeCl_3$ gives a light, transient green color, turning to orange; the concd. H_2SO_4 soln. is orange. II (12 g.) gives 11 g. of the *di-Me ether* (III), m. 74°. Heating 5 g. III with 20 cc. glacial AcOH and 10 cc. concd. HCl at 60° for 1 hr. gives 3.4 g. of *2-hydroxy-3,6-dimethoxyacetophenone*, bright-yellow, m. 61°; NaOH gives a yellow, concd. H_2SO_4 an orange, and $FeCl_3$ an intense blue-green color; it is only slightly volatile with steam; *Bz deriv.* (IV), m. 119°. Heating 5 g. IV with H_2SO_4 a bright orange-yellow, and $FeCl_3$ an intense reddish brown color; heating with AcONa in AcOH gives *5,8-dimethoxyflavone* (V), m. 144–5°; refluxing 0.5 g. with 5 g. $AlCl_3$ in 30 cc. Et_2O for 18 hrs. gives 0.15 g. of 5-hydroxy-8-methoxyflavone (VI), S-yellow, m. 209–10°, which is identical with the mono-Me ether of primetin; $FeCl_3$ gives an intense bluish green color; *Ac derv.*, m. 175–6°. Heating V or VI with HBr in AcOH gives 5,6-dihydroxyflavone, this being accompanied by a rearrangement involving the opening and closing of the heterocyclic ring. 2,6-$(HO)_2$-C_6H_3Ac (12.5 g.) and 17 g. NaOH in 150 cc. H_2O, treated dropwise with 24.4 g. $K_2S_2O_8$ in 500 cc. H_2O for 4 hrs. at 15–20°, give 4 g. of *2,3,6-trihydroxyacetophenone*, bright-yellow, decomps. above 230°; aq. NaOH gives a yellow color changing to a dark greenish blue; $FeCl_3$ gives a dull yellow-brown color; *tri-Ac deriv.*, m. 155°. 2,3-$(MeO)_2$-C_6H_3Ac and $AlCl_3$ in $CHCl_3$ give 2,3-HO(MeO)C_6H_3Ac, pale yellow, m. 54°; $FeCl_3$ gives an indigo-blue color; a sparingly sol. yellow Na salt is formed; oxidation with alk. $K_2S_2O_8$ gives *2,5-dihydroxy-3-methoxyacetophenone*, ocher-yellow, m. 172°; $FeCl_3$ gives a bluish green color; *di-Ac deriv.*, m. 127°. Oxidation of 2,5-HO(MeO)C_6H_3Ac with alk. $K_2S_2O_8$ gives *2,3-dihydroxy-5-methoxyacetophenone* (VII), yellow, m. 120°; $FeCl_3$ gives a green color; Pb-$(OAc)_2$ gives a yellow ppt.; a by-product is *2,2'-dihydroxy-5,5'-dimethoxy-3,3'-diacetylbiphenyl*, yellow, m. 202°; $FeCl_3$ gives a pale green color. Refluxing 1 g. VII, 0.8 g. Me_2SO_4 and excess K_2CO_3 in C_6H_6 for 10 hrs. and refluxing the oily product with BzCl and C_5H_5N give *2-benzoyloxy-3,5-dimethoxyacetophenone*, m. 142°; this did not give a methane with $NaNH_2$. *o*-Vanillin is oxidized by alk. $K_2S_2O_8$ to *2,5-dihydroxy-3-methoxybenzaldehyde* (VIII), yellow, m. 143°, which gives a transient green color with $FeCl_3$ and an orange color with aq. NaOH; a by-product is *4,4'-dihydroxy-3,3'-dimethoxybiphenyl-5,5'-dialdehyde*, yellow, m. 210°; $FeCl_3$ gives a greenish blue color and NaOH gives a yellow soln. VIII with Me_2SO_4 gives 2,3,5-$(MeO)_3C_6H_2CHO$, m. 63°, which is oxidized to 2,3,5-$(MeO)_3C_6H_2CO_2H$, whose *Me ester* b_{20} 178–80°; this ester and PhAc with Na under PhMe yield *2,3,5-trimethoxydibenzoylmethane*, pale yellow, m. 82°, which gives a deep reddish brown color with $FeCl_3$; it is decompd. on heating with HBr in AcOH. C. J. West

Quinovaic acid. VIII. Werner Schmitt and Heinrich Wieland. *Ann.* **542**, 258–73(1939); cf. *C. A.* **33**, 6862.—Novaquinone (I) (1 g.) in 150 cc. EtOH, treated with 4 cc. perhydrol and 400 mg. KOH in 12 cc. EtOH at 0° for 20 sec. and then with excess of H_2SO_3, the EtOH removed at 30–40°, the aq. layer extd. with Et_2O and the Et_2O with

satd. $NaHCO_3$, the $NaHCO_3$ soln. acidified and extd. with Et_2O, gives 80–90% of the *dilactonedicarboxylic anhydride* (II), m. 260° (decompn.); the acid (III) m. 285°. If very pure H_2O_2 is used, about 50% of the I is reduced to the dihydro deriv. (IV) and 50% is changed to II; in dioxane only IV results from the reaction with H_2O_2 (0.5 hr. at 100°). II with cold dil. MeOH-KOH gives the di-Me ester of III, m. 240°, which, warmed with *N* MeOH-KOH for a few min. and then treated with CH_2N_2, gives *tri-Me ester* of the *monolactonetricarboxylic acid* (V), $C_{33}H_{50}O_9$, m. 180°; V is stable to Br and gives no color with concd. H_2SO_4 or $FeCl_3$ in EtOH; it is unchanged on heating 1.5 hr. with Ac_2O, with PCl_5 in $SOCl_2$ or on warming with concd. H_2SO_4. Reduction of V with Zn in AcOH (boiling 3 hrs.) gives a compd., $C_{33}H_{50}O_8$ or $C_{33}H_{52}O_8$, m. 238°, which gives no color with $C(NO_2)_4$ or concd. H_2SO_4; in this reaction the CO group is reduced to a CHOH group and with the formation of an α,β-unsatd. ester; H_2O is split off; if the 2nd formula is correct, the double bond is also reduced. Heating V with *N* MeOH-KOH several min. on the steam bath gives a quant. yield of an *α-keto acid* (VI), $C_{32}H_{48}O_9$, m. 183°; no further change results after heating 3 hrs. On heating 600 mg. of VI in 4 cc. concd. H_2SO_4 at 35° while a stream of CO_2 is passed through, 90% of the theory of CO is split off in 2.5 hrs., giving 70% of the *mono-Me trans-C₂₉-monolactone tricarboxylate* (VII), m. 240–50° (decompn.); CH_2N_2 gives a *di-Me ester*, m. 179°. Heating VII at 250° gives the *anhydride* (VIII), m. 185°. With MeOH-KOH VIII yields the *cis*-isomer of VII, m. 190–200° (decompn.); *tri-Me ester*, m. 186°; on heating at 200° VIII is formed. A satd. soln. of I in EtOH and an excess of 2 *N* NH_3 give the *imine*, $C_{30}H_{41}O_8N$, m. 217°. IV and excess CH_2N_2 in Et_2O at 0° for 8 hrs. give an *isomer* of IV, m. 242° (decompn.); it does not give the $FeCl_3$ reaction and is stable to Br; with MeOH-KOH it gives a yellow soln. from which AcOH ppts. IV; oxidation yields I. IV with Me_2SO_4 in 4 *N* NaOH gives the *compd.* $C_{31}H_{41}O_8$, m. 192°; this contains 1 MeO group, is stable to Br, shows no $FeCl_3$ reaction and is not attacked by O_3 in EtCl or by MeOH-KOH. There is a discussion of the yellow derivs. of quinovaic acid. C. J. West

Preparation and reactions of karanjin. N. V. Subba Rao, J. Veerabhadrarao and T. R. Seshadri. *Proc. Indian Acad. Sci.* **10A**, 65–70(1939); cf. Manjunath, Seetharamiah and Siddappa, *C. A.* **33**, 2520⁸.—Karanjin (I), which was found to be useful for the treatment of leucoderma, was obtained in 0.9% yield by extg. pongamia oil (II) from the seeds of *Pongamia glabra* from Waltair for 30 hrs. with alc. in a special app. The yield varied with samples obtained from elsewhere. By shaking II with 2% of a mixt. of 2 parts concd. H_2SO_4 and 1 part H_2O cryst. K_2SO_4 was obtained; the protein mentioned by Desai, Sudborough and Watson (*C. A.* **17**, 3616) was not isolated. K was also found in the ash of II. I is only faintly bitter. By boiling I (2 g.) 3 hrs. with 3% aq. alc. KOH (100 cc. EtOH, 150 cc. H_2O, 7.5 g. KOH) with exclusion of air 0.9 g. karanjic acid was obtained in addn. to BzOH. I boiled with $Hg(OAc)_2$ in MeOH gave a yellow *diacetoxymercurikaranjin*, $C_{16}H_{10}O_4(HgOAc)_2$.
Dora Stern

Constitution of olive pigmentation. L. Musajo. *Boll. soc. ital. biol. sper.* **14**, 620–1(1939).—The coloring substance of the ripe fruit of *Olea europaea* L. is a rhamnoglucoside of cyanidin, the formula of whose chloride is $C_{27}H_{31}O_{15}Cl$. Helen Lee Gruehl

Long-chain alkyl derivatives of 2-aminopyridine. Thomas M. Sharp. *J. Chem. Soc.* **1939**, 1855–7.—2-Aminopyridine (I) (5.9 g.) in 25 cc. cymene and 1 mole of the appropriate alkyl halide are refluxed at 170–80° for 6–7 hrs.; the cymene is distd. off, the viscous residual oil is mixed with aq. NaOH and extd. with Et_2O; the resulting oil is distd. at 0.1–0.2 mm., taken up in Et_2O and shaken with H_2O and sufficient H_2SO_4 to render the aq. layer just acid to methyl red; evapn. of the Et_2O gives the 2-alkylaminopyridine; the sulfate of the 1-alkyl-2-pyridoneimine can be obtained from the aq. layer after evapn. but it is preferable to recover the base and convert it into the salt in dry alc. Decyl iodide gives a total yield of 10.5 g., of which 1.43 g. was *2-decylaminopyridine*, m. 51–2° (*picrate*, m. 78–9°); *1-decyl-2-pyridoneimine sulfate* (II), hygroscopic, m. 246° (decompn.); *picrate*, lemon-yellow, m. 111°. Undecyl bromide gives a yield of 9.6 g., of which 2.4 g. was the *undecyl deriv.* of I, m. 60–1° (*picrate*, m. 93–4°); the *undecyl analog* of II forms deliquescent needles not suitable for analysis; *oxalate*, effervesces at 205°; *picrate*, m. 116–17°. Dodecyl bromide gives 9.9 g., of which 2.6 g. are the *dodecyl deriv.* of I, m. 60° (*picrate*, m. 96–7°; *dodecyl analog* of II, m. 255° (decompn.); *picrate*, m. 88–9°. Tridecyl bromide gives 10.26 g., of which 2.6 g. are the *tridecyl deriv.* of I, m. 65–6° (*picrate*, m. 92–4°); *tridecyl analog* of II, m. about 265° (*picrate*, m. 88–93°). Tetradecyl chloride (III) gives 12.48 g., about half being the *tetradecyl deriv.* of I, m. 69° (*picrate*, m. 83°); *tetradecyl analog* of II, m. about 260° (*picrate*, m. 88°). I reacts with III in the presence of $NaNH_2$ to give only the deriv. of I. $PhCH_2Br$ gives 6.83 g., of which 1.42 g. was the benzyl deriv. of I; the *benzyl analog* of II m. 261° (decompn.). The dodecyl deriv. of I, heated 1 day with aq.-alc. KOH, did not form NH_3, whereas 1 g. of the dodecyl analog of II, refluxed with 20 cc. 50% aq. EtOH contg. 2 g. KOH, gave off NH_3 in 5 min. (completed in 56 hrs.) and yields 0.7 g. of 1-dodecyl-2-pyridone, whose *picrate*, yellow, m. 96–7°.
C. J. West

Sulfides and sulfones of pyridine and quinoline. A. R. Surrey and H. G. Lindwall. *J. Am. Chem. Soc.* **62**, 173–4(1940). —Refluxing a nearly satd. soln. of 2-chloro-5-nitropyridine in hot alc. and a slight excess of satd. aq. Na_2S for 4 hrs. gives 73% of *5,5'-dinitro-2,2'-dipyridyl sulfide* (I), yellow, m. 136–7°; reduction with $SnCl_2$ in concd. HCl gives 68% of the *di-NH₂ deriv.*, m. 80–1° and 130–1.5° (*di-Ac deriv.*, m. 265–6.6°); oxidation of 4.5 g. I in 80 cc. H_2O and 60 cc. concd. H_2SO_4 with 6 g. $K_2Cr_2O_7$ in 80 cc. H_2O gives 90% of the corresponding *sulfone*, m. 218.5–20.5°; *di-NH₂ deriv.*, m. 238–9°, 67% yield (*di-Ac deriv.*, m. 276–8°). *8,8'-Dinitro-5,5'-diquinolyl sulfide*, yellow, m. 280–1°, 90%; *5,5'-dinitro-8,8'-diquinolyl sulfide*, orange, m. 288.5–90°, 85%; oxidation of the latter with CrO_3 in AcOH (refluxing 15 min.) gives 54% of the *sulfone*, yellow, decomps. 245–60°.
C. J. West

Sulfanilyl derivatives of pyridine and quinoline amines. Robert Winterbottom. *J. Am. Chem. Soc.* **62**, 160–1 (1940). —Catalytic reduction of 7-nitroquinoline in Me_2CO with Raney Ni gives 95% of the NH_2 deriv. in 1 hr.; the 5- and 8-NH_2 isomers were obtained in 75 and 69% yield, resp. Acetylsulfanilyl chloride (I) (10 g.) and 4 g. 2-aminopyridine in 34 cc. Me_2CO contg. 5 cc. C_5H_5N give 9 g. of the *N¹-Ac deriv.*, m. 226–7° (all m. ps. cor.), of *2-sulfanilamidopyridine* (II), m. 190–1°; the Ac group is removed by refluxing with EtOH-HCl for 20 min. *3-Isomer* of II, m. 248–51° (decompn.); *N¹-Ac deriv.*, m. 272–5° (decompn.). I and 5-amino-2-acetylaminopyridine give 94% of the *N¹, 2-di-Ac deriv.*, m. 288–91° (decompn.), of *5-sulfanilamido-2-aminopyridine*, m. 210–11°. 3-Aminoquinoline (2.5 g.) and I in C_5H_5N, heated 2 hrs. on the water bath, give 5.4 g. of the *N¹-Ac deriv.* (III), m. 250–3° (decompn.), of *3-sulfanilamidoquinoline*, m. 185–6° (decompn.). The *HCl salt* of the *6-isomer* of III m. 238–40°. The 6- and 8-series were also prepd.
C. J. West

Coupling reactions of aminoquinolines with benzenediazonium chloride. A study of orientation in the quinoline ring. R. R. Renshaw, H. L. Friedman and F. J. Gajewski. *J. Am. Chem. Soc.* **61**, 3322–6(1939). —6-Aminoquinoline and PhN_2Cl in 0.25 *M* HCl (12 hrs.) or in AcOH-AcONa (10 min.) give *6-amino-5-phenylazoquinoline* (I), light-orange, m. 247–9°; the *HCl salt*, with 3 mols. H_2O, orange, m. 250–5° (the anhyd. salt results on heating at 120°). Reduction of I gives 5,6-diaminoquinoline (II), m. 135°. 7-Aminoquinoline in AcOH-AcONa gives *7-amino-8-phenylazoquinoline*, light orange, m. 170–3°; *HCl salt*, m. 210–11°; reduction with $SnCl_2$ and HCl gives *7,8-diaminoquinoline*, whose hydrate m. 95–7°; the *phenanthraquinone azine* m. 314°. 8-

Aminoquinoline gives *8-amino-5-phenylazoquinoline*, deep-orange, m. 133°; *HCl salt*, violet, m. 221–3°; reduction gives the 5,8-isomer (III) of II. 5-Aminoquinoline in dil. AcOH-AcONa gives 5-amino-8-phenylazoquinoline (IV), m. 191–4° (Jacobs and Heidelberger, *C. A.* **15**, 529, give 209–11°); in dil. HCl there results a mixt. of IV and of the 6-isomer; reduction of the mixt. gives mainly III and some II (identified as the azine, m. 294–5°). *py*-Aminoquinolines (V) were treated with PhN_2Cl under various conditions, since all solvents did not give pos. results. The 2-isomer of V in aq. MeOH or abs. EtOH gives small yields of 2-benzenediazoaminoquinoline (VI), light-tan, m. 165-6.5°; it is stable to hot dil. NaOH and HCl; the 3-isomer of VI results in dil. HCl-AcONa or dil. MeOH, light-tan, m. 156–7° (from H_2O) or 177–8° (from hot 10% NaOH) (both with decompn.); the difference in m. ps. is probably due to hydration; boiling dil. HCl gives the 3-isomer of V as does reduction with $SnCl_2$ and HCl. Coupling of the 3-isomer of V with PhN_2Cl in abs. EtOH gives *4-phenylazo-3-aminoquinoline*, light-red, m. 203–4°; HCl salt, dark-red, m. 228–30°; reduction gives 3,4-diaminoquinoline, m. 176.7° (*phenanthraquinone azine*, m. 280–1°). The 4-isomer of V did not couple under any condition tried; on mixing the components at −5° a light-red color appeared but rapidly faded with evolution of N; p-$O_2NC_6H_4N_2Cl$ gives a bright-red soln. at −10° which fades rapidly, giving the 4-isomer of V, N_2 and $PhNO_2$. *2-Benzenediazoamino-4-aminoquinoline*, orange-brown, m. 247.5–8.5°, is formed from 2,4-diaminoquinoline in dil. HCl and in better yields in dil. MeOH or AcOH; it is stable to boiling dil. HCl; the *2-p-nitrobenzenediazoamino deriv.*, orange, m. 315.5–16.5°; *HCl salt*, yellow, m. 323 5°. The above results are those to be expected from the application of the Erlenmeyer structure for quinoline. C. J. West

Preparation of 5,6-benzoquinoline. V. Sergeev. *Byull. Lako-Krasochnoĭ Prom.* **1938**, No. 2–3, 68–70; *Khim. Referat. Zhur.* **2**, No. 1, 102.—A method for the prepn. of 5,6-benzoquinoline from 2-naphthylamine, glycerol, H_3AsO_3 and H_2SO_4 is described. In a round-bottomed 1-l. flask equipped with a reflux condenser and with an elec. mixer place 25 parts of 2-naphthylamine, 54 parts of glycerol and 25 parts of H_3AsO_3. The mixt. becomes hot. While stirring constantly, heat the mixt. until reaction begins (very violently), remove the flame immediately, boil slowly for 2–3 hrs., dil. with water, and let the ppt. settle for 24 hrs. From the filtered sucked soln. sep. the 5,6-benzoquinoline with concd. KOH, dissolve the ppt. in HCl, boil several times with animal charcoal and filter. Obtain the base by pptg. it with KOH soln. The yield is 23 parts. W. R. Henn

Complexes of polynitro compounds. III. Compounds of polynitro substances with derivatives of carbostyril, etc. Andrew Kent, Donald McNeil and Robert M. Cowper. *J. Chem. Soc.* **1939**, 1858–62; cf. *C. A.* **32**, 2115⁴.—Details are given of compds. of *sym*-$C_6H_3(NO_2)_3$ (I) and picric acid (II) with carbostyril and its derivs. and various quinolones and quinolines. The most striking variation in the tendency for complex formation with I is provided among the C-methylcarbostyrils by the unique failure in this respect of the 6-Me deriv.; this appears to be constitutional and is contrary to the usually helpful influence of such substituents in amines or hydrocarbons; *N*-methylation of carbostyrils appears to reduce the probability of isolating homogeneous cryst. derivs. of I. The picrates obtained are manifestly "salt-like" in character if compared with the I complexes in color and m. p.; moreover they are frequently of different (i. e., 1:1) compn. Their similar ease of prepn. and moderate soly. in alc. suggests that the picrates of carbostyrils are not differentiated from 2-quinolone picrates as salts of "2-hydroxyquinolines," unless perhaps in the case of carbostyril picrates itself. These picrates may therefore be "H bond" adducts —NRC:O . . . HOX, stabilized by resonance. Picrates assumed to be "salt-like" in structure are indicated by the use of II as a suffix. Carbostyril (III) in EtOH gives the *complex* **I.2III**, S-yellow needles, m. 178°, and **III.II**, yellow needles, m. 132° (prepd. in Et₂O or from very concd. solns. in MeOH or EtOH). Thiocarbostyril (IV) in EtOH gives the *complex* **I.IV**, light-brown plates, m. 163–5° and **IV.II**, crimson needles, m. 145°. Dihydrocarbostyril (V) yields the *complex* **I.2V**, yellow plates, m. 137–8°. The 3-Me deriv. (**VI**) of III yields the *complex* I.2VI, light-yellow needles, and II.2VI, golden-yellow prisms, both with incongruent m. ps. The 4-Me deriv. (**VII**) of III yields the *complex* **I.2VII**, canary-yellow prisms, m. 226–7° and **VII.II**, light-yellow needles, m. 164–5°. 4-Methyl-2-thiocarbostyril (**VIII**) in $CHCl_3$ gives the *complex* I.2VIII, brown-yellow prisms, m. 190–2°, and 2VIII.II, orange-red plates, m. 193–5°. The *5-Me deriv.* (**IX**) of III m. 222–3°; it forms a *complex* **I.2IX**, light-yellow needles, m. 222–3°, and **IX.II**, yellow prisms, m. 156–7°. The 6-Me deriv. (**X**) of III forms the *complex* **X.II**, pale-yellow needles, m. 171–2°. The 6-Me isomer (**XI**) of VIII forms a *complex* **I.2XI**, orange prisms, m. 159–61° (in $CHCl_3$), and scarlet prisms with II (compn. not detd.), m. 140–2°. The *7-Me deriv.* (**XII**) of III m. 192–3°; it forms a *complex* **I.2XII**, canary-yellow needles, m. 203–4°, and **XII.II**, light-yellow needles, m. 163°. The 8-Me deriv. (**XIII**) of III forms the *complex* **I.2XIII**, golden-yellow needles, m. 181°, and **XIII.II**, light-yellow needles, m. 128–9°. The 4,6-di-Me deriv. (**XIV**) of III yields the *complex* **I.2XIV**, golden-yellow prisms with an incongruent m. p., and **XIV.II**, canary-yellow needles, m. 188°. The 4,7-di-Me deriv. (**XV**) of III forms a *complex* **I.2XV**, S-yellow needles, m. 213–14°, and **XV.II**, light-yellow needles, m. 189–91°. The 4,8-di-Me deriv. (**XVI**) of III gives a *complex* **I.2XVI**, S-yellow needles, m. 199–200°, and **XVI.II**, canary-yellow needles, m. 192–4°. 1-Methyl-2-quinolone (**XVII**) gives a complex **I.XVII**, light-yellow laminated plates, m. 77–9°, and **XVII.II**, yellow needles, m. 128–9°. 1-Methyl-2-thioquinolone (**XVIII**) yields the *complex* **I.2XVIII**, orange needles, m. 98–9°, and **II.2-XVIII**, orange prisms, m. 104°. 1,6-Dimethyl-2-quinolone (**XIX**) yields the *complex* **XIX.II**, canary-yellow needles, m. 150°. The *1,7-isomer* (**XX**) of **XIX** (pale yellow, m. 107–8°) gives a *complex* **I.XX**, pale yellow needles, m. 106–7°, and **XX.II**, lemon-yellow prisms, m. 132°. The 1,8-isomer (**XXI**) of **XIX** gives the *complex* **XXI.II**, canary-yellow needles, m. 134°. 2-Methoxyquinoline (**XXII**) forms the *complex* **I.XXII**, yellow plates, m. 89–90°, and **XXII.II**, yellow needles, m. 170–1° 2-Methylthioquinoline (**XXIII**) gives the *complex* **I.XXIII**, deep-yellow needles, m. 99–100°, and **XXIII.II**, yellow plates, m. 183–4°. 2-Methoxy-6-methylquinoline (**XXIV**) yields the *complex* **I.XXIV**, greenish yellow prisms, m. 72–3°, and **XXIV.II**, greenish yellow plates, m. 181–2°. The compd. **XXIII.II** was first obtained from IV and Me picrate (**XXV**) in MeOH; that it is not a mol. compd. follows from the synthesis by bubbling MeSH through MeONa in MeOH, adding 2-chloroquinoline in MeOH, boiling 2 hrs. and adding II. **XI** and **XXV** in boiling MeOH give *2-methylthio-6-methylquinoline picrate*, golden-yellow plates, m. 196–7°. **XVIII** and **XXV**, boiled 10 min. in MeOH, give *2-methylthio-1-methylquinolinium picrate*, deep-yellow plates, m. 175°; 1,6-dimethyl-2-thioquinolone was recovered unchanged even after 2 hrs. boiling. Crystn. of I from 6-methylquinoline gave the binary compd., pale-yellow needles, m. 63–5°; the 8-isomer afforded an analogous product, pale yellow with incongruent m. p. *2-Chloro-7-methylquinoline*, m. 81° (*picrate*, canary-yellow plates, m. 113–14°). *3-Methylquinoline oxide-HCl*, m. 192–4° (*picrate*, greenish yellow needles, incongruent m. p.). *6-Methylquinoline oxide-HCl*, m. 172–3° (*picrate*, pale-yellow needles, m. 174–5°). *1,6-Dimethyl-2-thioquinolone*, yellow, m. 137°. I and dibenzyl-*o*-toluidine give relatively lightly colored EtOH solns. which pptd. only the constituents; melts of these compds. in the proportions 1:1, 1:2 or 2:3 give viscous red liquids, disintegrated to colorless powders. *Dibenzyl-o-toluidine picrate*, canary-yellow prisms, m. 120–1°. Dibenzyl-*m*-toluidine (**XXVI**) and I in concd. EtOH soln. give a *compd.* **I.3XXVI**, ruby-red prisms, m. 71–2°; a soln. contg. the reactants in the ratio of 2:3 gives successive crops of complex until reduced to dryness; the

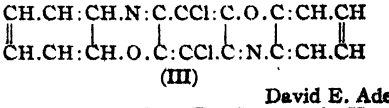
picrate of XXVI, yellow prisms, m. 126–7°. The *p*-isomer (XXVII) of XXVI and I (2:1 in EtOH) give the *complex* I.2XXVII, ruby-red needles, m. 62–4°; the *picrate* of XXVII, golden-yellow plates, m. 174–5°. I and 1-thiocoumarin in concd. C_6H_6 or EtOH soln. give colorless solns. which pptd. only the components; the *picrate*, yellow needles, m. 148°; *trans-o*-aminocinnamic acid gives a binary *complex* with I, brick-red needles, m. 131°. I and 2-thiocoumarin in EtOH give the binary *complex*, light-brown plates, m. 87°. 2,4,5-Trinitrotoluene and $(4\text{-}Me_2NC_6H_4)_2CH_2$ give a binary *complex*, dark-red needles, m. 92–3°; 2,4,6-$(O_2N)_3C_6H_2Me$ and *p*-$C_6H_4(NO_2)_2$ did not afford cryst. derivs. The m.-p. curves are given for I with VII, X and XVII. C. J. West

Synthetic experiments on 4-aminohydrocarbostyril and its derivatives. Takaoki Sasaki and Hidenosuke Ueda. *Proc. Imp. Acad.* (Tokyo) **15**, 315–20(1939); cf. *C. A.* **33**, 8617⁶.—*o*-$O_2NC_6H_4CH(NH_2)CH_2CO_2H$ (I) (4.2 g.) in a little NaOH, shaken with excess of $ClCO_2Me$ and acidified with dil. H_2SO_4, gives 93% of *o-nitro-*(*β-carbomethoxyamino*)*hydrocinnamic acid*, m. 165–6°; reduction with $FeSO_4$ in 10% NH_4OH (heating 0.5 hr. on the water bath) gives 91% of *4-carbomethoxyaminohydrocarbostyril*, with 0.5 mol. H_2O, m. 127–9° (decompn.); hydrolysis gives carbostyril (II). I gives 94% of the *Ac deriv.*, pale-yellow, m. 177°; reduction gives a nearly quant. yield of *4-acetylaminohydrocarbostyril*, m. 233–4°. The *chloroacetyl deriv.* of I m. 178° (95% yield); heating with NH_4OH (d. 0.9) at 100° for 1 hr. gives the *β-glycylamino deriv.*, with 1.5 mols. H_2O, m. 230° (decompn.); reduction gives 55% of *4-glycylaminohydrocarbostyril*, m. 147°, which was isolated as the *sulfate*, m. 220° (decompn.); *Bz deriv.* (*4-hippurylaminohydrocarbostyril*), m. 227°. I yields 95% of the *Bz deriv.*, m. 233°; reduction gives 91% of *4-benzoylaminohydrocarbostyril*, m. 220 1°; hydrolysis gives II. The *β-carbobenzoxyamino deriv.* of I m. 152° (80% yield); reduction gives II. The free NH_2 group of I is very labile and easily split off, so that 4-aminohydrocarbostyril cannot be prepd. C. J. West

ms-**Derivatives of acridine. XII. 9-Chloroacridine and acridol.** N. S. Drozdov. *J. Gen. Chem.* (U. S. S. R.) **9**, 1373–5(1939); cf. *C. A.* **33**, 4595⁹.—Previously it was shown (*C. A.* **29**, 7334²) that when *ms*-chloroacridine (I) is treated with O in $PhNO_2$ (Marzin, *C. A.* **27**, 5332) and boiled in acid soln. or steam-distd. (Graebe and Lagodzinskii, *Ann.* **276**, 49(1893)), the resulting reaction product is not acridol but acridone in varying amts. According to Lehmstedt (*C. A.* **29**, 6893⁸) I does not react with O in $PhNO_2$. Further expts. showed that freshly recrystd. I is not oxidized or hydrolyzed into acridone, while a stored product is considerably reactive. It is evident that I on standing, particularly under the influence of daylight, is converted into the reactive complex ($C_{13}H_9ON$.-$C_{13}H_8NCl$).HCl (cf. *loc. cit.*). 2-Methyl-9-chloroacridine behaves like I and gives the reactive complex ($C_{14}H_{11}ON$.-$C_{14}H_{10}NCl$).HCl. Thus, the conflicting data on the relative reactivity of I and its derivs. can be explained by the use of products of different degrees of decompn. in storage.

XIII. The preparation and antimalarial action of substituted 9-aminoacridine. O. M. Cherntsov and N. S. Drozdov. *Ibid.* 1435–40.—Following previous procedures several new dialkylaminoalkyl derivs. of 9-aminoacridine are prepd. by the interaction of primary amines and their HCl salts with 9,9-diphenoxyacridans and 9-phenoxyacridines (*C. A.* **30**, 3432⁸) and the cyclization of substituted diphenyl-2-carboxylic acids (cf. D., *C. A.* **33**, 4251⁶). *2-Dimethylamino-9-*(*γ-piperidino-β-hydroxypropylamino*)*acridine*, red crystals, m. 213–15°, was prepd. in 50% yield from 1 g. 2-dimethylamino-9-phenoxyacridine (I) (cf. D. and Bekhli, *C. A.* **33**, 4595⁹) and 3-piperidino-2-hydroxypropylamine (II) with 10 g. PhOH by digesting 1–2 hrs. on a water bath and pouring the melt into alc. 10% NaOH; *6-Cl deriv.*, red crystals, m. 115–16°, resulted in 83% yield from 1 g. 2-dimethylamino-6-chloro-9-phenoxyacridine (III) and 0.5 g. II with 6 g. PhOH. *2-Dimethylamino-9-*(*γ-diethylamino-β-hydroxypropylamino*)*acridine*, reddish yellow viscous oil, (67%), obtained from 1.5 g. I and 0.9 g. 3-diethylamino-2-hydroxypropylamine (IV) with 7 g. PhOH; *6-Cl deriv.* (V), red-orange crystals, m. 108–9° (78%), formed from 2 g. 2-diethylamino-6-chloro-9-phenoxyacridine and 0.5 g. IV with 5 g. PhOH. *2-Dimethylamino-9-*(*δ-diethylamino-α-methylbutylamino*)*acridine* (68%), reddish oil, obtained from 1.7 g. I and 1 g. 1-diethylamino-4-aminopentane (VI) with 5 g. PhOH; *6-Cl deriv.* (VII), reddish yellow heavy oil, prepd. in 68% yield from 0.9 g. III and 0.5 g. VI with 5 g. PhOH. *2-Methoxy-9-*(*δ-diethylamino-α-methylbutylamino*)*acridine* (VIII), yellow fine crystals, resulted in 29% yield from 2.6 g. 4-methoxydiphenylamine-2-carbonyl chloride and 1.7 g. VI in 30 ml. C_6H_6 with 6 g. $POCl_3$, dissolving the filtered oily substance in alc. and pptg. with dil. NH_4OH. *3-Chloro-7-methoxy-9-*(*γ-piperidino-β-hydroxypropylamino*)*acridine* (IX), yellow fine needles, m. 130–1.5°, prepd. in 69% yield from 2.5 g. 3,9-dichloro-7-methoxyacridine (X) and 1.5 g. II with 10 g. PhOH. IX.HCl m. 255° (decompn.). *2-Nitro-7-methoxy-9-*(*γ-piperidino-α-hydroxypropylamino*)*acridine*, red crystals, m. 170–1° (72%), formed from 0.7 g. 2-nitro-7-methoxy-9-phenoxyacridine (*C. A.* **30**, 2195⁵) and 0.35 g. II with 4 g. PhOH. *1-Nitro-4-methoxy-9-methylaminoacridine*, dark yellow needles, m. 211–13°, from 0.15 g. $MeNH_2$.HCl, 3 g. PhOH and 0.4 g. 1-nitro-4-methoxy-9-phenoxyacridine, m. 231–2°. The latter was prepd. by fusing 0.9 g. 1-nitro-4-methoxy-9-chloroacridine with 5 g. PhOH and decompg. the HCl salt with dil. NH_4OH in alc. *p-*(*3-Chloro-7-methoxy-9-acridylamino*)*benzenesulfonamide* (XI), does not melt 300°, prepd. in 94% yield by heating 3 hrs. 1.4 g. X and 0.9 g. *p*-$H_2NC_6H_4SO_2NH_2$ with 5 g. PhOH and decompg. the HCl salt with concd. Na_2CO_3. It is insol. in H_2O, sparingly sol. in org. solvents and fairly sol. in C_5H_5N. All these aminoacridine derivs., except XI, were tested for their *physiol. action* in bird malaria. V, VII, VIII and IX showed considerable antimalarial action. C. B.

Heterocyclic compounds. X. The synthesis of substituted 1,2,3,4-tetrahydroacridones. Wahid Bukhsh and R. D. Desai. *Proc. Indian Acad. Sci.* **10A**, 262–6(1939); cf. *C. A.* **33**, 3356²; Hughes and Lions, *C. A.* **33**, 6115.—5-Methyl-, 7-bromo-, 5- and 7-methoxy- and 7-ethoxy-1,2,3,4-tetrahydroacridones were synthesized by condensing Et cyclohexanone-2-carboxylate with *o*-toluidine, *p*-bromoaniline, *o*- and *p*-anisidine and *p*-phenetidine, resp., by means of concd. HCl and heating the Et 2-arylamino-1-cyclohexene-1-carboxylates $CH_2.CH_2.CH_2.CH_2.C(CO_2Et):CNHR$, formed at 240–50°. 4- and 2-Methyl-1,2,3,4-tetrahydroacridone were prepd. by condensing 2- and 4-methylcyclohexanone with anthranilic acid at 120° and heating the 1-(*o*-carboxyanilino)-6- and -4-methyl-1-cyclohexenes, $MeC_6H_8NHC_6H_4CO_2H$, formed at 220°. $\Delta^{1 \text{ or } 2}$-Octahydronaphthacridone was obtained in a similar way by condensing *trans-β*-decalone with anthranilic acid to 2-(*o*-carboxyanilino)-$\Delta^{1 \text{ or } 2}$-*trans*-octalin and cyclizing the latter. *Et 2-arylamino-1-cyclohexene-1-carboxylates: o-toluidino*, m. 84–5°; *p-bromoanilino*, m. 77–8° (yield 5.5 g. from 4 g. *p*-bromoaniline); *o-anisidino*, m. 79–80° (yield 3 g. from 2.5 g. *o*-anisidine); *p-anisidino*, m. 71–2° (yield 3.5 g. from 2.5 g. *p*-anisidine); *p-phenetidino*, m. 88°. *1-*(*o-Carboxyanilino*)*-6-methylcyclohexene*, m. 130°; yield 5.5 g. from 5 g. anthranilic acid. *1-*(*o-Carboxyanilino*)*-4-methylcyclohexene*, m. 143°; yield 6 g. from 5 g. anthranilic acid. *2-*(*o-Carboxyanilino*)-$\Delta^{1 \text{ or } 2}$-*trans-octalin*, m. 164–5°; yield 7 g. from 6 g. anthranilic acid; the *monohydrate* m. 82°. *Substituted 1,2,3,4-tetrahydroacridones: 5-Me*, m. 355–8°; *7-Br*, does not m. 350°; *5-MeO*, m. 277–9°; *7-MeO*, m. 285–6°; *7-EtO*, does not m. 350°; *4-Me*, m. 345°; *2-Me*, does not m. 350°. $\Delta^{1 \text{ or } 2}$-*Octahydronaphthacridone*, does not m. 350°. Dora Stern



Reaction between hydrogen selenide, formaldehyde and secondary amines. Arthur H. Binz, Francis E. Reinhart and Harry C. Winter. *J. Am. Chem. Soc.* **62**, 7–8 (1940).—Morpholine (12 cc.) in 75 cc. H_2O, cooled in an ice bath and satd. with H_2Se and then poured into a cold

soln. of 37% HCHO (75 cc.) in 150 cc. H_2O, gives 9.1 g. of ***bis(4-morpholylmethyl) selenide*** (I), m. 136–8°; when a soln. of 0.7842 g. of I in 115 cc. of 80% EtOH at 40° is shaken in an open flask for 15 min., 98.1% of the total combined Se pptd. as elementary Se. Piperidine (11.6 g.), added slowly to 20 cc. 37% HCHO cooled in an ice bath, gives 3 g. of crude 1-piperidinemethanol which, satd. with H_2Se in Et_2O, gives 1.8 g. of ***bis(1-piperidylmethyl) selenide*** (II), m. 67°; this decomps. in H_2O. Both I and II are highly toxic when injected intravenously into rats, the lethal dose being of the order of 0.012–0.017 g. per kg. of body wt. Me_2NH and $(HOCH_2CH_2)_2NH$ gave oils which could not be purified. C. J. West

Analogs of ephedrine and adrenaline containing the morpholine nucleus and some of their esters. Nathan Rubin and Allan R. Day. *J. Org. Chem.* 5, 54–60 (1940).—To prep. compds. which have the combined effect of a local anesthetic and a vasoconstricting action, morpholine (I) is condensed with phenacyl bromide (III), phenethyl bromide (II), α-bromopropiophenone (IV), *p*-hydroxyphenacyl chloride (V) and 3,4-dihydroxyphenacyl chloride (VI). The amino ketones so obtained are catalytically reduced to the corresponding carbinols. The attempt is made to prep. from the amino ketones the corresponding hydantoins according to Bucherer (*C. A.* 29, 127[1]) but this is successful only in the case of ω-morpholinoacetophenone. Addn. of 18.5 g. II in 30 cc. EtOH to 17.4 g. I in 25 cc. EtOH gives 17.7 g. 4-phenethylmorpholine-HCl (VII), m. 246° (cor.). In the same way I and III give ω-morpholinoacetophenone-HCl (VIII), m. 222–3° (cor., decompn.) in 80–90% yield. With IV and I α-morpholinopropiophenone-HCl (IX), m. 224° (cor., decompn.), is obtained in 80–5% yield. When a soln. of 6.12 g. I is slowly added to 6 g. V in 10 cc. EtOH at a temp. below 15°, ***ω-morpholino-p-hydroxyacetophenone*** (X), m. 201–1.7° (cor.), is obtained in 90% yield. Its *HCl salt* m. 242–3° (cor., decompn.). I and VI give ***ω-morpholino-3,4-dihydroxyacetophenone*** (XI), m. 207° (cor., decompn.), in 85–90% yield; *HCl salt*, decomps. 224–5° (cor.). Reduction of VIII with Pd-charcoal in alc. yields ***1-phenyl-2-morpholinoethanol-HCl*** (XII), m. 188 8.7° (cor.) in 87.5% yield; its *free base* m. 80.9–1.3° (cor.); the *Bz deriv.* of XII m. 173.5–5°; the *cinnamate* m. 220–1°. In the same way reduction of IX gives ***1-phenyl-2-morpholino-1-propanol-HCl*** (XIII), m. 235° (cor.), in 80 5% yield; its *free base* m. 73–3.5°; the *Bz deriv.* m. 210–11°. Catalytic reduction of X give ***1-(p-hydroxyphenyl)-2-morpholinoethanol-HCl***, m. 178° (cor., decompn.), in 78% yield, and reduction of XI gives ***1-(3,4-dihydroxyphenyl)-2-morpholinoethanol-HCl***, decompg. at 250°, in 81–98% yield. When to 5 g. VIII in 40 cc. 50% EtOH, 2 g. KCN and 8 g. $(NH_4)_2CO_3$ is added and the mixt. heated on a water bath for 8.5 hrs. at 55–65°, ***5-phenyl-5-morpholinomethylhydantoin***, m. 204–4.5°, crystallizes in 93% yield; its *HCl salt* m. 206° (cor., decompn.). F. E. Brauns

Semiquinone radicals of the thiazines. L. Michaelis, M. P. Schubert and S. Granick. *J. Am. Chem. Soc.* 62, 204–11(1940).—A semiquinone radical is shown to exist as a univalent reduction product for thionine (I) and for methylene blue (II). In equil. with the dye and the leuco dye, it can exist only to a few percent of the total dye *in maximo* over the whole pH range covered by the customary buffers. In very strongly acid soln., such as from 10 to 26 *N* H_2SO_4, it is stable to a much higher extent and can be identified by an analysis of the reductive titration curve of the dye and by its color, which is yellow with distinct absorption bands in the blue. The semiquinone formation const. *k* reaches for I the value 1000 in 26.6 *N* H_2SO_4 but rapidly decreases to values less than 1 in less acid solns. For II this const. reaches in 22.9 *N* H_2SO_4 only the value 6. In a wide pH range around neutrality, *k* for both dyes is approx. 0.05. The greater stability of the radical in very acid soln. is ascribed to the formation of a bivalent cation having a structure, exhibiting equiv. resonance, of the same type as a Wurster radical. The existence of this radical is correlated with the reversibility of oxidation-reduction of thiazines and with their catalytic effect in biol. oxidations. C. J. West

Triphenodioxazine. Hans E. Fierz-David, Jacob Brassel and Fritz Probst. *Helv. Chim. Acta* 22, 1348–58(1939).—The yield (280 g.) and purity of 2,5-dichloro-3,6-di-*o*-anisidinoquinone (I) (Ger. pat. 253,091) were improved by adding 230 g. freshly distd. *o*-anisidine in small portions to a well-stirred mixt. of 200 g. $C_6Cl_4O_2$ (II), 150 g. anhyd. AcONa and 1 l. *o*-$C_6H_4Cl_2$ and refluxing for 3 hrs. By adding 100 g. I to a hot, well-dispersed mixt. of 250 g. anhyd. $AlCl_3$ and 1300 g. dry C_5H_5N and refluxing for 20 hrs., 80 g. 9,10-dichlorotriphenodioxazine (III) is obtained; III crystallizes from $PhNO_2$ as red needles which have no m. p. and give a blue color with concd. H_2SO_4. III is formed if the anilide or the *o*-phenetidine deriv. is used instead of the anisidine deriv.; the last 2 derivs. may be condensed to the dioxazine with $PhNO_2$ with or without addn. of $FeCl_3$. Addn. of 35 g. 1,2,5-$HOC_6H_3(NH_2)NO_2$ in 200 cc. alc. to 25 g. II and 20 g. AcONa in 400 cc. alc. followed by refluxing for 20 hrs. gives 35–40 g. 2,6-dinitro-9,10-dichlorotriphenodioxazine (IV) directly. Similarly, 3,7,9,10-tetrachlorotriphenodioxazine is obtained from 1,2,4-$HOC_6H_3(NH_2)Cl$. Reduction of IV by alk. $Na_2S_2O_4$ gives a blue dihydrodiamino deriv. which is oxidized by H_2O_2 to ***2,6-diamino-9,10-dichlorotriphenodioxazine***, $C_{16}H_{10}Cl_2N_4O_2$ (V); all yields are quant.; V appears as green leaflets from *s*-$C_6H_3Cl_3$. 3,7-Dinitro-9,10-dichlorotriphenodioxazine may be converted into the corresponding diamine in similar fashion. The condensation product from picramic acid and II is converted by concd. H_2SO_4 into ***1,3,5,7-tetranitro-9,10-dichlorotriphenodioxazine***, $C_{18}H_4Cl_2N_6O_{10}$, which forms Cu-colored crystals from $PhNO_2$ and imparts a violet-blue color to concd. H_2SO_4. Treatment of the condensation product (25 g.) from II and 1,2,4,5-$H_2NC_6H_2OMe(HNBz)Me$ with BzCl in $PhNO_2$ yields 13 g. ***2,6-di(benzoylamino)-3,7-dimethyl-9,10-dichlorotriphenodioxazine***, $C_{24}H_{22}Cl_2N_4O_4$; the latter is also obtained by reduction of the condensation product from 1 mol. of II and 2 mols. of nitrocresidine followed by benzoylation. Condensation of II with 1,2,5-$C_6H_4NH_2(OEt)_2$ followed by benzoylation in $C_6H_4Cl_2$ yields ***3,7-diethoxy-9,10-dichlorotriphenodioxazine***, $C_{32}H_{16}Cl_2N_2O_4$, which is green and which gives a blue soln. with concd. H_2SO_4; the *di-MeO deriv.* may be prepd. in similar fashion. ***2,3,5,6-Dibenzo-9,10-dichlorotriphenodioxazine***, $C_{32}H_{16}Cl_2N_2O_4$ (VI), which is green, is formed by condensation of II and β-$C_{10}H_7NH_2$ in $PhNO_2$; yield, 90%; VI is changed by 20% fuming H_2SO_4 into a reddish violet ***dye for wool.*** ***3,4,7,8-Dibenzo-9,10-triphenodioxazine*** is easily prepd. from α-$C_{10}H_7NH_2$, but cannot be obtained from 1,2,-$H_2NC_{10}H_6OEt$. ***- D1(1′ - naphthylamino) - 3,6-dichloro-1,4-benzoquinone*** (VII) is prepd. by refluxing for 7 hrs. a mixt. of 49.2 g. II, 63 g. freshly distd. α-$C_{10}H_7NH_2$, 39.3 g. anhyd. AcONa and 2 l. alc.; yield 35 g. (38.9%). Refluxing VII for 15 hrs. in $PhNO_2$ gives the ***dioxazine***, $C_{26}H_{12}Cl_2N_2O_2$, in 44% yield. Condensation of 4-phenylazo-1-naphthylamine (VIII) with II in alc. followed by heating in $PhNO_2$ contg. *p*-$MeC_6H_4SO_2Cl$ yields a green dioxazine, $C_{38}H_{20}Cl_2N_6O_2$ (IX) (Swiss pat. 180,698); sulfonation of IX gives a bluish green ***dye for wool and silk.*** IX is also obtained if the monoazo dye from $PhNH_2$ and 1,2-$MeOC_{10}H_6NH_2$ is used instead of VIII; by starting with 1,4-$BrC_{10}H_6NH_2$ a dibromodioxazine is obtained. When III is refluxed with $PhNH_2$ and $PhNH_3Cl$, a blue product results, $C_{36}H_{24}ClN_5O_2$. Refluxing the condensation product from II and 1,2,4-$H_2N(MeO)C_6H_3NHPh$ with C_5H_5N and $AlCl_3$ gives 2,6-dianilino-9,10-dichlorotriphenodioxazine. App. is described for extn. of solids by high-boiling solvents.

(III)

David E. Adelson

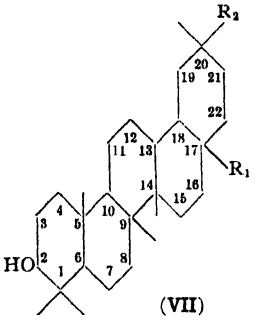
Synthesis of vitamin B_6. II. Stanton A. Harris and Karl Folkers. *J. Am. Chem. Soc.* 61, 3307–10(1939); cf. *C. A.* 33, 5397[4].—The original synthesis of vitamin

B_6 (**XI**) is represented by the reactions 3-cyano-4-ethoxymethyl - 5 - nitro - 6 - methyl - 2 - pyridone (I) → 2 - methyl - 3 - nitro - 4 - ethoxymethyl - 5 - cyano - 6 chloropyridine (V) → *2 - methyl - 3 - amino - 4 - ethoxymethyl - 5 - cyano - 6 - chloropyridine* (VI) → 2-methyl-3 - amino - 4 - ethoxymethyl - 5 - aminomethylpyridine (VII) → 2 - methyl - 3 - hydroxy - 4 - ethoxymethyl-5-hydroxymethylpyridine (VIII) → 2 - methyl-3-hydroxy-4,5-bis(bromomethyl)pyridine-HBr (**XII**) → **XI**. The key compd. in the improved synthesis is **VII**, which has been prepd. by 2 variations of these reactions: I → *5-amino analog* (II) → VI → VII and I → II → VI → *di-Ac deriv.* (III) → *2 - methyl - 3 - diacetylamino - 4 - ethoxymethyl - 5 - aminomethylpyridine* (IV) → VII. These variations are limited by the low yield in the reaction II → VI. Reduction of I with Adams catalyst in EtOH or AcOH gives 63.6% II, m. 250-5° (decompn.); reduction of I in Ac_2O gives 53.4% of the *acetate* of II, m. 260°; boiling II with an excess of Ac_2O gives a *diacetate*, m. 176°. II (2 g.) with 4 g. PCl_5 in 15-20 cc. $POCl_3$, allowed to stand overnight at 30°, gives 16.5% of VI, m. 146-7°; warm Ac_2O gives the *mono-Ac deriv.*, m. 134-6°; boiling Ac_2O for 30 min. gives 82.5% III, m. 90-2°. Reduction of 3.09 g. of III in 100 cc. AcOH contg. 0.82 g. of AcONa with 10 g. Pd-C and 0.5 g. Adams catalyst (absorption of 3 mols. H) gives 36.4% IV, whose *picrate* m. 190-1°; decompn. of the picrate with 1:1 HCl and hydrolysis by boiling for 1.5 hr. with 15% HCl gives VII, whose di-HCl salt m. 204-5° (after drying at 100° in a high vacuum); a *monohydrate*, m. 127-9°, results on crystn. from 95% EtOH. Variations in the synthesis of **XI** are represented by the reactions VII → VIII → **XI** and VII → *2 - methyl-3-amino - 4 - bromomethyl - 5 - aminomethylpyridine - 2HBr* (**IX**) → *di-HCl salt* (**X**) of the *4-hydroxymethyl analog* of **IX** → **XI** or VII → **X** → **XI**. Heating 1.55 g. of VII with 20% of boiling 48% HBr until about 0.5 of the acid has been distd. gives **IX**, m. 260-5°; heating with hot H_2O and stirring with AgCl gives **X**, m. 235-7°; VII is converted to **X** in 76.7% yield by heating 2.24 g. in 34 cc. of 2.5 *N* HCl for 4 hrs. at 175-80°. Through the diazo reaction **X** gives 45.4% of **XI**. VIII, m. 135-6°, heated with 2.5 *N* HCl at 155-60° for 6 hrs., gives 83% of **XI**; cleavage of VIII by heating 0.2 g. in 6 cc. concd. HCl at 132° for 1 hr. gives 45% of *2-methyl-3-hydroxy-4,5-bis(chloromethyl)-pyridine-HCl* (**XIII**), m. 206°; heating 50 mg. **XIII** with 10 cc. H_2O on the steam bath for 1 hr. gives 10 mg. **XI**. In recrystg. **XI** prepd. by the hydrolysis of **XII**, there results some *2-methyl-3-hydroxy-4,5-(epoxydimethoxy)-pyridine* (**XIV**), m. 239-40° (decompn.); **XIV** also results in small yields when **XI** or VIII is treated with 15 cc. of 50% H_2SO_4 for 1 hr. on the steam bath. **XIV** resists hydrolysis by heating with 2.5 *N* HCl at 175° for 4 hrs.; distn. with 48% HBr gives 86.5% of **XII**, m. 228.5°. C. J. West

Cinchona alkaloids. XXXI. Characterization and preparation of epiquinine and epiquinidine. Paul Rabe and Helmut Höter. *J. prakt. Chem.* **154**, 66-72(1939); cf. *C. A.* **33**, 3385².—Epiquinine (I) and epiquinidine (II) form a *sulfate*, I.II.$H_2SO_4.6H_2O$, $[\alpha]_D^{20}$ 38.5° (H_2O, *c* 0.5909); placed in a bath at 95° it m. 101-3°, decomps. 115°; at room temp. 1 part dissolves in 4 parts H_2O. I forms a *HBr salt*, with 3 mols. H_2O, m. 71-7°, $[\alpha]_D^{20}$ 32.9° (H_2O, *c* 0.7592), sol. in about 14 parts H_2O at room temp., easily sol. in hot H_2O. II, m. 113°, is best crystd. from AcOEt. The *IIBr salt*, with 1 mol. H_2O, m. 240° (slow heating); it is sol. in 3.4 parts of H_2O at room temp.; the thiocyanate, II.HCNS, m. 193°, $[\alpha]_D^{20}$ 44.5° (H_2O, *c* 0.4496); it is very difficultly sol. in H_2O and seps. from hot H_2O as an oil. Details are given of the rearrangement of quinine with AmOH-KOH, the sepn. of quinidine as the tartrate, the pptn. of I and II as the double sulfate and the isolation of II as the HSCN salt and of I as the HBr salt in 66 and 77% yield, resp. C. J. West

Erythrophleum alkaloids. I. Cassaine, a crystalline alkaloid from the bark of Erythrophleum guineense (Don). G. Dalma. *Helv. Chim. Acta* **22**, 1497-1512(1939); cf. *C. A.* **33**, 7810⁷.—Pulverized bark (5 kg.) from *Erythrophleum guineense* (I) (coastal forests near the mouth of the Congo) was treated with 10% NH_4OH and exhaustively extd. with ether. The ext. was concd., washed with 5% KOH and treated with 0.5 *N* HCl contg. $NaHSO_3$. The acid soln. was washed with ether, made alk. and extd. with ether. Treatment of the ether soln. with concd. H_2SO_4 in Et_2O pptd. cassaine bisulfate (II) which was crystd. from alc.-ether mixt. II was converted to III repptd. as II by addn. of H_2SO_4 and recrystd. Treatment of II with KOH soln. followed by ether extn. gave 5 g. cassaine (III), m. 138-40°. Repeated crystn. of II from alc.-ether yielded the pure compd., $C_{24}H_{39}NO_4.H_2SO_4.2H_2O$, m. 290° (*in vacuo*) (decompn.). By treating pure II with KOH, III, $C_{24}H_{39}NO_4$, is obtained; crystd. from ether, III m. 142.5°, $[\alpha]_D^{20}$ −111° (95% alc.), −103° (abs. alc.); −117° (0.1 *N* HCl). I.*HCl.H₂O*, m. 212-13°; *Ac deriv.* of III, m. 123-4°; *oxime* of III, m. 123-5°. Hydrolysis of 5 g. of III with *N* HCl gave 3.5 g. *cassainic acid*, $C_{20}H_{30}O_4$ (IV), crystals from ether, then Me_2CO-H_2O, m. 203°, $[\alpha]_D^{20}$ −126.3° (95% alc.). *Me ester* (V) of IV, crystals from MeOH-H_2O, m. 189-90°; *Ac deriv.* of V, m. 189-91°; *semicarbazone* of V, m. 246-7°. Alk. hydrolysis of 5 g. of III gave 2.9 g. of *allocassainic acid*, $C_{20}H_{30}O_4$ (VI), m. 222-4°, $[\alpha]_D^{20}$ 81.8° (95% alc.). Treatment of III with 10% CrO_3 in AcOH at 35-40° gave *dehydrocassainic acid*, $C_{20}H_{28}O_4$ (VII), crystals from Me_2CO-H_2O, m. 238-9°, $[\alpha]_D^{20}$ −164.5° (95% alc.). *Me ester* (VIII) of VII, m. 129-30°; *dioxime* of VIII, m. 130-2°; *disemicarbazone* of VIII, m. 290° (decompn.). Extn. of 1 kg. of I from the Ucle region of central Congo gave 5.5 g. of a base that appeared to be identical with Merck's Erythrophlein. Extn. of 2.5 kg. of I from the forests on the lower side of the Congo gave 0.25 g. of a base identical with III. II. **The carbon skeleton and position of the double bond in cassainic acid.** L. Ruzicka and G. Dalma. *Ibid.* 1516 23.—Hydrogenation of cassaine (I) in AcOH over PtO_2 at room temp. gave dihydrocassaine, $C_{24}H_{41}NO_4$ (II), m. 115-16°; $[\alpha]_D^{20}$ 0 ± 2° (95% alc.), −6.5 ± 1° (0.1 *N* HCl). Hydrogenation of I over Raney Ni also gives II. Alk. hydrolysis of II yielded *hydroxyketocassainic acid*, $C_{20}H_{32}O_4$ (III), m. 253-5° (*in vacuo*), $[\alpha]_D^{20}$ 0 ± 2° (95% alc.), −5 ± 1° (0.1 *N* NaOH). Reduction of III by Na-alc. gave *dihydrocassainic acid*, $C_{20}H_{34}O_4$ (IV), m. 262-5° (*in vacuo*), $[\alpha]_D^{20}$ −7 ± 1° (0.1 *N* NaOH); *Me ester* of IV, m. 172-4°. Dehydrogenation of IV with Se at atm. pressure and 340° gave 1,7,8-trimethylphenanthrene (V), m. 142 3°; *sym*-$C_6H_3(NO_2)_3$ adduct, m. 192-3°; picrate, m. 133-5°; all of these were identical with known specimens. When IV was dehydrogenated with Se in a sealed tube at 340°, a mixt. of V and its tetrahydro deriv. (VI) was obtained which was sepd. and identified as the *sym*-$C_6H_3(NO_2)_3$ adducts, m. 192-3° and 85-8°, resp. Dehydrogenation of VI with Se at atm. pressure and 340° gave V. Ultraviolet absorption spectra studies were carried out with several derivs. of I. I showed a max. at 2230 A. (log ε 4.26), cassainic acid at 2150 A. (log ε 4.3) and Me diketocassainate at 2230 A. (log ε 4.2), indicating a double bond in the α,β-position to the carboxyl group. Allocassainic acid did not exhibit an absorption band characteristic of α,β-unsatd. acids, thus suggesting that alk. hydrolysis of I shifted the double bond β,γ to the carboxyl. III showed a max. at 2800 A. (log ε 1.64). IV exhibited no absorption between 2000 and 3400 A., indicating a complete hydrogenation of the keto groups and the double bonds originally present. The ultraviolet absorption spectra are valuable tools in following the transformations of I into its various derivs. David E. Adelson

Constituents of the leaves of Leucothoe keiskei Miq. Haruya Simada. *J. Pharm. Soc. Japan* **59**, 619-20(in German, 242-4)(1939).—The leaves of *Leucothoe keiskei* (1.62 kg.) were extd. with ether and hydrolyzed with 10% alkali. The K salt gave with HCl ursolic acid, $C_{29}H_{47}CO_2H$, m. 289-90° (all m. ps. cor.), $[\alpha]_D^{13}$ 69.4°; Me ester, m. 171-2°; acetate, m. 295-6°. The Me acetylursolate m. 246-7°. The neutral fraction of the ether soln. gave uvaol, $C_{30}H_{50}O_2$, m. 232-3°; acetate, m. 157-9°. F. I. Nakamura



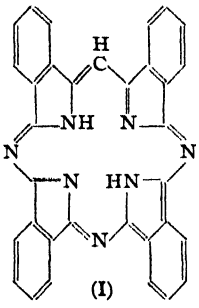
Synthesis of rubierythric acid, the chief glucoside of

Rubia tinctorum. Géza Zemplén. *Math. naturw. Ans. ung. Akad. Wiss.* **58**, 380–92(1939).—As rubierythric acid is according to the newest statements a β-2-primeveroside of alizarin, a synthesis from alizarin and acetobromoprimeverose has been successfully tried. The attempted synthesis with quinoline and Ag_2O was without result, nor could the product be obtained by treatment of β-2-triacetylalizaringlucoside (I) with α-acetobromoxylose, since the former compd. was very little sol. To produce I alizarin was dissolved in quinoline and treated with Ag_2O. Its long yellow needles m. 234–6°. The acetylated deriv. m. 199–200°, $[\alpha]_D^{18}$ −84.8° ($CHCl_3$). The treatment of acetobromocellobiose with sublimed alizarin in acetone and KOH led to yellow rhombic crystals of β-2-heptaacetylalizarincellobioside (II), m. 244–6°. The acetylation of II with pyridine and anhyd. AcOH gave yellow needles of β-2-octaacetylalizarincellobioside (III), m. 224–5°, and $[\alpha]_D^{18}$ −70.90° ($CHCl_3$). The successful synthesis was begun by dissolving sublimed alizarin and acetobromoprimeverose in acetone, adding KOH and shaking. The filtrate was then evapd. *in vacuo* and shaken out with $CHCl_3$ several times. The $CHCl_3$ fractions were united and washed out with dil. NaOH; the last wash liquid showed the bright red color of the glucoside instead of the blue of alizarin. The acetylation of the raw product obtained from this $CHCl_3$ soln. led to light yellow needles of β-2-heptaacetylalizarinprimeveroside (IV), $C_{39}H_{40}O_{20}$, m. 221–3.5°. The sapon. of IV in alc. by means of 33% NaOH gave finally the yellow needles of β-2-alizarinprimeveroside (rubierythric acid), m. 256–8°.
S. S. de Finály

A constituent of the fruit of Pyracantha angustifolia Schneid (Rosaceae). Haruya Simada. *J. Pharm. Soc. Japan* **59**, 621–3(in German, 255–6)(1939).—The fruit of *Pyracantha angustifolia* Schneid (1.1–2.1 kg.) was extd. with ether and hydrolyzed with a 10% alk. soln., which gave ursolic acid. The aq. soln. gave *d*-sorbitol, m. 73°, in a yield of about 9%, which was identified as the hexa-Ac or triformal deriv. The dry fruit contains also about 1.3% sugar as glucose.
F. I. Nakamura

Saponins and sterols. XIV. Anhydro derivatives of ursolic acid. Katuya Huzii and Sigeiti Ōsumi. *J. Pharm. Soc. Japan* **59**, 660–3(in German, 237–9)(1939); cf. *C. A.* **33**, 4979⁶.— Me ursolate (5 g.) when treated with 5 g. P in 200 cc. dry petr. ether gave after standing overnight Me ursylenate (I), $C_{31}H_{48}O_2$, m. 163.5°. An attempt to obtain an isomeric form of I with Zn-Hg failed. I (5 g.) when heated with alc. KOH at 145–50° (12–13 atm. pressure) gave ursylenic acid (II), $C_{30}H_{46}O_2$, m. 266–8°. Reduction of II (0.6 g.) in alc. with 6 cc. 1% $PdCl_2$ soln. and 0.3 g. C gave ursenic acid, $C_{30}H_{48}O_2$, m. 203.5°; Me ester, $C_{31}H_{50}O_2$, m. 138–40°. Hydrolysis of Me ursolate, Me sanquisorbigeninate and Me oleanolate with alc. KOH at 155° at a reduced pressure gave the corresponding acids quantitatively.
F. I. Nakamura

Saponins and sterols. XV. Dry distillation of ursolic acid with selenium and its constitution. Katuya Huzii and Sigeiti Ōsumi. *J. Pharm. Soc. Japan* **59**, 711–17(in English, 264–8)(1939); cf. preceding abstr.—Ruzicka and van Veen (*C. A.* **24**, 856) have previously obtained sapotalene (I) by dry distn. of ursolic acid (II) with Se, and Drake and Duvall (*C. A.* **30**, 7571⁹) isolated 2,7-dimethylnaphthalene (III) and 1,8-dimethylpicene. H. and O. have now isolated, besides I and II, 1,2,3,4-tetramethylbenzene (IV), 1,2,5,6-tetramethylnaphthalene (V) and 1,2,5-trimethyl-6-hydroxynaphthalene (VI). From the results of dry distn., the authors propose the formula VII for the structure of II (any one of the groups R_1 and R_2 represents CO_2H and the other Me). The reasons for proposing this structure are as follows: From the nature of the dry distn. products, it is assumed that II and oleanolic acid (VIII) have the same C skeletal structure. The OH groups should be located at C_2 due to the formation of VI. The double linkage is stable toward catalytic reduction like those present in triterpenes and hence it should be present at C_9-C_{10} or C_{12}-C_{13} as in VIII. Since Me ursolate is difficult of sapon. its CO_2H group should be of tertiary type and should not be located at C_1 (R., Giacommello and Grob, *C. A.* **32**, 3367⁶). If the CO_2H and the OH groups are in the 1,3- or 1,4-positions, it should give γ- or δ-lactones with $ZnCl_2$ and glacial AcOH, but instead, it gives ursylenic acid (preceding abstr.), showing they are not at these positions. II does not give a Br lactone



(VII)

or Ac lactone (Winterstein and Stein, *C. A.* **26**, 732), showing that the double bond exists at ε-ζ or some other positions further removed with respect to the CO_2H group. *Exptl.*—The mixt. of 40 g. II and 80 g. Se powder is heated 36 hrs. at 330–50°, and extd. with ether. After evapg. off the solvent, the residue is sepd. by distn. into the following fractions: (a), 40–70°, (b) 70–100°, (c) 100–5°, (d) 105–20°, (e) 120–8°, (all above fractions at 4 mm.) and (f) 120–60° (0.15 mm.) From fraction (a), IV is isolated. Tribromide, m. 219–20° (cor.), From (b), the picrate of III, m. 135–6° (cor.), is obtained, which on decompn. gives crystals of III, m. 97°. From (c) III is isolated; picrate, m. 128–9° (cor.); styphnate, m. 157°.
Nao Uyei

Constituents of "Senso." X. Isomers of anhydrogamabufotalin. Heisaburo Kondo and Setuo Ōno. *J. Pharm. Soc. Japan* **59**, 531–7(in German, 186–9)(1939); cf. *C. A.* **33**, 2528³·⁴.—Gamabufotalin (I) (0.5 g.) when refluxed on the water bath for 4 hrs. with alc.-H_2SO_4 gave an anhydro compd. (II), $C_{24}H_{32}O_4$, m. 204° (with $1H_2O$, m. 125–7°). Diacetylgamabufotalin when treated as above gave a compd. m. 125–7° Acetylation of II gave a compd., $C_{26}H_{34}O_5.H_2O$, m. 125; *p*-nitrobenzoate, m. 219–21°. I when treated with 0.5 *N* alc. HCl gave II. I when treated with *N* alc. HCl gave a compd., $C_{24}H_{32}O_4$, m. 258–9°, depressed the m. p. of I from 261–2° to 232°. I and concd. HCl gave a compd. (III), m. 258–9.° I in a mixt. of alc. and ether when treated with dry HCl gas gave III. The acetate of III did not crystallize, but analysis gave $C_{24}H_{32}O_4(C_2H_2O)_2$. I and HBr gave $C_{24}H_{33}O_4Br$. Catalytic reduction of 0.384 g. III gave a neutral compd. (0.17 g.), whose *p*-nitrobenzoate m. 184°, and an acidic compd. (0.2 g.), $C_{24}H_{40}O_4$, m. 210–12° (dihydroxycholanic acid). Catalytic reduction of 0.138 g. of II gave an acidic compd., $C_{24}H_{40}O_4$, m. 199–201°, isomeric with dihydroxycholanic acid, and a neutral compd. whose benzoate m. 185–90°.
F. I. Nakamura

Phthalocyanines and related compounds. XV. Tetrabenzotriazaporphine: its preparation from phthalonitrile and a proof of its structure. P. A. Barrett, R. P. Linstead and G. A. P. Tuey, with a note on a preliminary x-ray investigation by J. M. Robertson. *J. Chem. Soc.* **1939**, 1809–20; cf. *C. A.* **32**, 8423⁸.—*Tetrabenzotriazaporphine* (I) is best prepd. as follows: MeMgI (from 2.4 g. MeI and 6.5 cc. MeI in 100 cc. Et_2O) is added to a mixt. of 12.8 g. of finely powd. phthalonitrile (II) and 500 cc. Et_2O; the Et_2O is allowed to boil off during the reaction and after a few hrs. the remainder is removed on the steam bath and the residue is rapidly heated to 200°; 3 cc. H_2O are gradually added to the product; after heating 0.5 hr. at 200°, the cooled and powd. residue is extd. with a mixt. of EtOH and 10% HCl; the crude pigment is freed from Mg by soln. in concd. H_2SO_4, filtration and pptn. with ice, followed by crystn. from $C_{10}H_7Cl$. The yield of I is 4.7 g. (about 40%). I forms needles or plates with a strong purple reflex; a dil. $C_{10}H_7Cl$ soln. gives only needles.

The spectra of the 2 forms are identical. X-ray examn. gave *b* 4.725 A. (phthalocyanine (III) has a value of *b* of 4.72 A.); the structure, dimensions and arrangement of the I mols. in the crystal are almost or completely identical with those in the corresponding III mol. The spectrum of I shows max. at 6940, 6635 (inflexion), 6520, 6380, 6220, 5920, 5700, 4620 A.; corresponding values of log ε are 5.19, —, 5.03, 4.75, 4.66, 4.43, 4.03, 4.03. Values for III are 7030, 6680, 6360, 6040, 5760, 5560; log ε 5.23, 5.22, 4.75, 4.52, 4.02, 3.88. When I is heated in a stream of CO_2 under reduced pressure it tends to melt and then sublimes in lustrous needles. I is more resistant toward oxidizing agents than is III, but can be completely oxidized by both acid $KMnO_4$ and acid $Ce(SO_4)_2$; the oxidation follows the formula: $I + 5O + 5H_2O \rightarrow 4C_6H_4(CO)_2NH + CO_2 + 3NH_3$. $KMnO_4$ oxidation yields 84% of $C_6H_4(CO)_2NH$ (on the basis of the equation) and at the same time 3 moles of NH_3 are liberated. Under similar conditions III yields 4 moles of NH_3. For measuring the O uptake quantitatively, rather more drastic conditions than those for the oxidation of III are necessary, the I being heated at 100° with a considerable excess of $Ce(SO_4)_2$; an amt. of O corresponding to nearly 5 atoms per mole is then taken up. Under the same conditions III takes up only 1.1 atoms of O per mole and the method is therefore suitable for the estn. of mixts. of the macrocyclic pigments. In the $Ce(SO_4)_2$ oxidation III gives hardly any CO_2, whereas I gives 1 mole. These results exclude the possibility of I being a methylated III. In the $Ce(SO_4)_2$ oxidation the initial blue-green pigment becomes purple but the purple compd. reverts to the original pigment so readily as to prevent its isolation. Reducing agents such as $SnCl_2$ brought about the reversal instantaneously. The purple compd. is fairly stable to dil. H_2SO_4 but is very rapidly dissolved by the addn. of more $Ce(SO_4)_2$. II, treated with an equimol. amt. of MeLi at 0° and the product heated to about 200° with cyclohexanol, gives about 15% of a pigment approxg. in compn. to I; however, this appears to contain some tetrabenzodiazaporphine or a similar less nitrogenous pigment. Under these conditions only a small proportion of the Me groups supplied in the reagent appear as methine groups in the final product; the action of a deficiency of MeLi on II gives a better yield of total pigment (35%) but the product contains a large proportion of III. BuLi gives a mixt. of a triaza compd. and III. The results indicate that the tendency for organometallic compds. to yield macrocyclic pigments contg. C links is greatest with Me derivs.; those contg. larger groups tend to give more III and even with Me reagents some III can be formed under suitable conditions. If 2 moles of MeLi and 1 mole of II are caused to react in Et_2O and the residue is heated at 200° with cyclohexanol for 0.5 hr., there results *3-amino-1,1-dimethylisoindole* (IV), m. 146°; *picrate*, canary-yellow, m. 255°. IV results in 4–8-g. yields from 25 g. II in 100 cc. C_6H_6 with MeMgI from 32 cc. MeI in Et_2O, allowed to react with cooling for 7–8 min. and decompg. with NH_4Cl. IV is a strong base and displaces NH_3 from NH_4Cl. In the prepn. of I from equimol. quantities of II and MeMgI an excess of the II remains at the end of the 1st condensation; this nitrile is clearly responsible for the N links in I; possible mechanisms of the formation of I are discussed.

(I)

Heating I with an excess of Cu bronze in boiling quinoline for 12 hrs. gives the *Cu deriv.* (V), needles with purple luster, which sublimes *in vacuo*; V also results on adding powd. CuCl to the soln. of II in MeMgI, followed by heating at 200° as outlined above; V may also be prepd. from *o*-NCC_6H_4Ac (Helberger and von Rebay, *C. A.* **31**, 5370[9]). The spectrum of V shows max. at 6840, 6550, 6270, 6140, 6000, 4460 A.; log ε 5.21, 5.01, 4.58, 4.57, 4.49, 4.15. X-ray examn. of V gave a value of 4.78 A. for *b* (the Cu salt of III gave a value for *b* of 4.79 A.). V is oxidized by acid $Ce(SO_4)_2$ but the reaction is slower than with I and about 4.7 atoms of O are taken up. Concd. H_2SO_4 gives a brownish green soln. of V, giving a bluish green ppt. on dilu.; addn. of a drop of HNO_3 gives a deep greenish blue color; more acid gives a red color, changing to brown. Boiling I with $CuCl_2$ in $C_{10}H_7Cl$ for 8 hrs. gives *Cu monochlorotetrabenzotriazaporphine*, greenish blue, which cannot be sublimed; absorption spectrum max. at 6830, 6560, 6450, 6000 A. The Zn (VI) and Mg (VII) salts of I may also be prepd. from I and the metal. VI gives a spectrum with max. at 6780, 6540, 6260, 6130, 5980, 4440, 4265 A.; log ε 5.23, 5.00, 4.43, 4.42, 4.38, 4.20, 4.51; VII is more sol. than the other salts and a limited quantity of quinoline should be used in its prepn.; VII is also obtained by reaction of I and MeMgI and after the heating period, freeing the product from impurities by extn. with EtOH and extg. the residue directly with $C_{10}H_7Cl$; 12.8 g. II gives 5.1 g. VII; spectral bands of VII at 7220, 6810, 6580, 6300, 6150, 6000, 4480 A.; log ε 4.36, 4.96, 4.82, 4.30, 4.38, 4.18, 4.18. On standing in air VII appears to hydrate as does the Mg salt of III but no definite compd. was isolated. Boiling 5 g. I and 2.5 g. $FeCl_2$ in 100 cc. quinoline for 0.5 hr., dilg. with 8 vols. C_6H_6, removing the quinoline with dil. HCl and crystg. the ppt. from $C_{10}H_7Cl$ gives the *ferrous salt*, bronze needles, spectral bands in $C_{10}H_7Cl$ at 6570, 6350 (diffuse to 6260), 5820 A; log ε 4.74, 4.67, 4.23; like the ferrous deriv. of III, it is sol. in $PhNH_2$ and gives large crystals of a solvated pigment; it is also sol. in C_5H_5N. The Li deriv. of I is sol. in cold EtOH, Me_2CO, etc. **XVI. The halogenation of phthalocyanines.** P. A. Barrett, E. F. Bradbrook, C. E. Dent and R. P. Linstead. *Ibid.* 1820–8.—The halogenation of phthalocyanine (I) proceeds readily under conditions which do not effect halogenation of *o*-$C_6H_4(CN)_2$ or $C_6H_4(CO)_2O$; as in the case of aromatic compds., under mild conditions I forms addn. compds. with halogens. The position of the halogen atoms in these compds. is unknown. They are easily converted, particularly by heat, into substitution products in which the halogen atoms enter the C_6H_6 nuclei. In both processes the I skeleton is preserved. I reacts rapidly at room temp. with Br in CCl_4 without elimination of HBr. The amt. of halogen removed from the soln. depends upon the concn. and reaches a max. at 8 g.-atoms per g.-mol. of I. When the insol. octabromide is warmed with alkali, all the halogen is removed and I is reformed. Most of the halogen is also removed if the dry octabromide is heated. If the product is left in contact with Br in CCl_4 for several weeks, a slow irreversible fixation of halogen occurs and the final product contains up to 40% of Br not removable by warm alkali. The same change can be effected more readily by heating the octabromide in high-boiling solvents. The 2 stages in the reaction correspond with addn. and with substitution in the C_6H_6 rings. The substituted bromophthalocyanines formed in this way will still add a further 8 g.-atoms of Br from CCl_4 soln. When I is heated with Br to 300° under pressure, both addn. and substitution occur. Much HBr is evolved and a brown solid is formed. After the additive Br has been removed, a green bromophthalocyanine contg. over 60% of stable Br remains. The limit of substitution obtainable in this way appears to be reached when 13 of the 16 nuclear H atoms have been replaced. Lower temps. give less highly brominated products. The addn. of Cl resembles that of Br but is less easily followed quantitatively. At room temp. Cl gas converts free I and many of its metallic derivs. into brown chlorides, from which the halogen is completely liberated by warm alkali. When, however, I is heated at 250° with liquid Cl

under pressure, addn. and substitution both occur and the brown product yields a green dodecachlorophthalocyanine on treatment with alkali. These high-temp. reactions provide another illustration of the great stability of the I ring. I can also be chlorinated by the action of $SOCl_2$, SO_2Cl_2, PCl_5 + $POCl_3$ and other reagents; no addn. products appear and HCl is at once evolved; the products are blue to blue-green and not very highly chlorinated. When heated with SO_2Cl_2 under pressure at 230°, I gives a green Cl deriv. contg. 13 atoms of Cl per mol. High chlorination can be achieved without the use of pressure by passing Cl gas through a suspension of I in $SOCl_2$ at the b. p. This reaction is assisted by the presence of catalysts, particularly S_2Cl_2, C_5H_5N and I; the products are green and contain from 10 to 13 atoms of Cl per mol. ($SbCl_5$ in $C_6H_4(CO)_2O$ also gives a high degree of chlorination); if $AlCl_3$ or $FeCl_3$ is used, the metal becomes attached to the center of the I ring and cannot be displaced. Reaction also occurs in fuming H_2SO_4 but considerable fission results and the yields are small. Iodination has not been realized. Typical Cl derivs. of I yield their Cu and Pb derivs. with Cu and PbO_2 in high-boiling solvents, showing that the central acid H atoms are not affected by the halogenation. On the introduction of the 1st 4 atoms of halogen the color becomes slightly duller but is otherwise very little changed; further substitution leads to progressively greener shades, a pure green being obtained when about 10 atoms of halogen have been introduced. Chlorination of I leads to an increase of soly. in $C_{10}H_7Cl$ until about 8 atoms of Cl have been introduced; more highly chlorinated derivs. are very sparingly sol.; the soly. of the Br derivs. decreases after 4 atoms are introduced. With the entry of halogen atoms the soly. of I in H_2SO_4 decreases and the color of the soln. progressively changes to a brownish red. Oxidative fission of the Cl derivs. to chlorophthalimides and hydrolysis by H_2SO_4 at 170° gives the chlorophthalic acids or the anhydrides; 3 acids were isolated: 4-Cl (II), 4,5-di-Cl (III) and the tetra-Cl deriv. (IV); a I with 5.5 g.-atoms Cl per mol. gives 53% II; with 8.2 g.-atoms 22% III and 3% IV; with 10 g.-atoms (made with $SbCl_5$) 23% III and 19% IV; (made without $SbCl_5$) 33% III and 26% IV; with 13 g.-atoms 5% III and 50% IV; the yields are expressed in terms of the corresponding chloroisoindole corners of the I mol. The results indicate that nuclear substitution occurs preferentially in the 2 β (4 and 5) positions; substitution is uneven. The absorption spectra of the Cl derivs. show that introduction of Cl generally leads to a slight progressive shift of the absorption max. toward the red and to a weakening or extinction of the weaker bands of the I spectrum; owing to the lack of symmetry, the spectra of the chlorination products were not sharply defined, particularly after 8 Cl atoms had been introduced. Solns. of the pigments in concd. H_2SO_4 generally showed only a broad area of transmission from green to red. This was shifted toward the red by chlorination, particularly by substitution in the 3,6-positions; the octachlorinated pigment resembled the 4,5- rather than the 3,6-deriv. The transmission in H_2SO_4 did not approach that of the 3,6-compd. until 12 or 13 Cl atoms had entered the mol. C. J. West

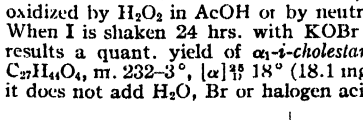
Bile pigments. XXVII. Synthesis of 4,4'-dimethyl-3,3'-diethyl-5,5'-diaminopyrromethenes. Hans Fischer and Herbert Guggemos. *Z. physiol. Chem.* **262**, 37–46 (1939); cf. *C. A.* **33**, 5864[3].—Treatment of 4,4'-dimethyl - 3,3' - diethylpyrromethane - 5,5' - dicarboxylic hydrazide with $NaNO_2$ below 3° gave *4,4'-dimethyl-3,3'-diethyl-5,5'-dicarbazidopyrromethane* (I), m. 127° (decomp.), which on treatment with $PhNH_2$ at 140° gave *4,4' - dimethyl - 3,3' - diethylpyrromethane - 5,5' - diphenylurea*, m. 235°. I reduced with Zn and HOAc below 70° gave *4,4'-dimethyl-3,3'-diethylpyrromethane-5,5'-dicarboxamide*, m. 300°, with 1 mol of HOAc of crystn. I treated with Br in Et_2O gave *4,4'-dimethyl-3,3'-diethyl-5,5'-dicarbazidopyrromethene* (II) as the HBr salt, m. 133°, which on treatment with pyridine in H_2O gave the free *base*, m. 130°. Refluxing I with EtOH gave 4,4'-dimethyl-3,3'-diethylpyrromethane-5,5'-diethylurethan, m. 124–5°. II under the same conditions gave *4,4'-dimethyl-3,3'-diethylpyrromethene-5,5'-diethylurethane*, m. 147°. II on boiling in 50% HOAc gave β,γ-diimidoetioporphyrin II (III). I on boiling with 50% HOAc for 1 hr. gave *4,4'-dimethyl - 3,3' - diethyl - 5,5' - diaminopyrromethane diacetate* $C_{19}H_{32}N_4O_4$, m. 185°, which on heating with 4% NaOH for 2 hrs. and sepn. by chromatography gave *4,4'-dimethyl-3,3'-diethyl-5,5'-diaminopyrromethene* (IV), decompn. 157° with the formation of III. IV forms a *Cu complex*, m. above 350°, which is sol. in $CHCl_3$, etc., and is stable even to H_2SO_4. Milton Levy

Constitution of yeast ribonucleic acid. III. The nature of the phosphatase-resistant group. J. Masson Gulland and Elisabeth M. Jackson. *J. Chem. Soc.* **1939**, 1842–4; cf. *C. A.* **33**, 6260[7].—A mixt. of 5 g. of Boehringer yeast ribonucleic acid in the min. amt. of dil. NaOH, Clark and Lubs' borate buffer at pH 8.6 (200 cc.), purified phosphomonoesterase soln. (100 cc.) and Russell's viper venom (0.1 g.) were dild. to 500 cc. with H_2O and incubated at 37°; when the liberation of phosphate had ceased (75%), a ppt. of guanine was removed and the filtrate treated with $Ba(OH)_2$; after filtration of the Ba phosphate, MeOH pptd. a Ba salt (I) which was not obtained pure but which yields adenine on acid hydrolysis. The filtrate from I, neutralized with AcOH and treated with excess $Pb(OAc)_2$, gives a Pb salt (II). Decompn. of II with H_2S gives guanosine and uridine. The Pb salt of the nucleotide fraction yields a *nucleotide* (III), $C_9H_{14}O_8N_3P$, decomps. about 220°. Comparison of the low rates of acid hydrolysis of I and III with those of adenylic and guanylic acids indicates that they are pyrimidine nucleotides. Both I and III suffer dephosphorylation with mutton-bone phosphomonoesterase; Russell's viper venom liberated no phosphate from I in 72 hrs. but III slowly underwent dephosphorylation; this is the 1st occasion in which liberation of phosphate has been effected by this venom in the case of a deriv. of a nucleic acid and in terms of current views may possibly indicate that the phosphoryl radical is substituted for a H atom of the NH_2 group or of the HO at C_6 of cytidine. Hydrolyses with enzyme prepns. from sweet-almond cake came to a standstill when about 75% dephosphorylation had occurred and the addn. of fresh enzyme did not cause further fission; the course of the hydrolysis thus seems to be similar to that effected by both monoesterase and Russell's viper venom. Acid hydrolysis of the nucleotide fraction yielded adenine and cytidine, whereas the nucleoside fraction contained guanosine and uridine. It therefore seems established that the phosphatase-resistant group is assocd. with the cytidylic and adenylic radicals. C. J. West

Bile acids. LVII. Oxidation of the oximinoketohydroxamic acid, $C_{24}H_{38}N_2O_8$, by potassium permanganate. Martin Schenck. *Z. physiol. Chem.* **261**, 273–7(1939); cf. *C. A.* **33**, 8621[4].—Oxidation of the oximinoketohydroxamic acid, $C_{24}H_{36}N_2O_8$ (*C. A.* **28**, 1428[6]), by $KMnO_4$ in NaOH gives N_2 and cilianic acid, the latter probably resulting from the bilianic acid first formed. **LVIII. Behavior of the diketohydroxamic acid, $C_{24}H_{35}NO_8$, and other hydroxamic acids toward alkaline potassium permanganate.** *Ibid.* **262**, 47–52.—Hydroxamic acids generally give gases on treatment with alk. $KMnO_4$ soln. The gas may be chiefly N_2O as with acetohydroxamic and benzohydroxamic acids or chiefly N_2 as with the diketohydroxamic acid, $C_{24}H_{35}NO_8$ (*C. A.* **23**, 4482) or the β-acid, $C_{24}H_{34}N_2O_{10}$, and its corresponding amino acid (*C. A.* **32**, 7053[6]). The α-acid, which is isomeric with the β-acid, gives no N_2. The primary action of alk. $KMnO_4$ is supposed to be the reaction —CO(NHOH) → —CO_2H + $(OH)_2NH$ (or O:NH); the nitroxyl dimerizes to nitrosohydroxylamine, $H_2N_2O_2$, or a similar compd. This may split to N_2O and H_2O or to N_2 and H_2O if a reductant is present. Bilianic acid oxime lactam gives no gas. Milton Levy

Bile acids. LVII. Separation of the contents of cattle bile. Heinrich Wieland and Walter Seibert. *Z. physiol. Chem.* **262**, 1–19(1939); cf. *C. A.* **31**, 1032[6].—Hydroxycholanic acids can be sepd. by extn. of their Et_2O solns. with aq. HCl. Thus 15% HCl exts. cholic acid (I) completely without extg. desoxycholic acid (II) or 3,7-dihydroxycholanic acid (III); 25% HCl exts. II and III

completely but very little 3-hydroxycholanic acid and no cholanic acid. Esters are also extd. but much more slowly than the acids. Extn. is probably due to formation of oxonium salts. The crude acids (570 g.) from 10 l. of sapond. winter cattle bile were shaken with 0.5 l. of EtOH and the residue (crude I) sepd. by acid extn. from Et_2O and shown to contain fat acids and II in small amts. The alc. soln. was evapd. to 0.25 its vol., sapond. to remove esters and distd. to remove EtOH, and the liberated acids transferred to Et_2O, leaving a residue of resins derived from bile pigments. From the ether soln. I was extd. with 15% HCl and II and III sepd. from the residue. A balance sheet of these and minor fractions shows the isolation of 439.9 g. of I, 81.2 g. of II, 12 g. of III, 3.7 g. of cholesterol, traces (0.3 g.) of bile acids, 17.0 g. of pigments and 38.1 g. of fat acids, totalling 592.2 g., from the original material. The excess represents accumulated solvents in the materials weighed. The fat acids appear to be chiefly oleic acid. The trace fraction was esterified with CH_2N_2 and sapond. with alc. KOH which saponifies only the esters of lithocholic acid until autoclaved, when esters of *sapocholic acid* (IV) are sapond. The latter were fractionated with ether and KOH solns., giving 6.95 g. of sapocholic acid from 1.25 kg. of crude material. In addn., small amts. of ursolic and oleanolic acids were isolated and identified. These sapogenins probably are not metabolic products but come directly from the feed. IV forms a cryst. K salt and an *Ac deriv.* (V) $C_{32}H_{50}O_4$, m. 231.3°; *Me ester*, m. 185–6°. Free IV obtained cryst. after sapon. of Me acetyl sapocholate shows a double m. p. when dried below 175°. It first m. 207–12° with gassing, solidifies below 220° and m. again at 235–7°. The first m. p. is probably that of the solvated substance. V when titrated with alkali indicates a mol. wt. corresponding with the formula $C_{30}H_{48}O_3$ for IV. Milton Levy



Preparation and properties of 3(α),11-dihydroxy-12-ketocholanic acid. Bernard B. Longwell and O. Winterstein. *J. Am. Chem. Soc.* **62**, 2003–3 (1940). 3-Hydroxy-12-ketocholanic acid (I) forms a *3-Ac deriv.*, m. 197–8°. Refluxing 5 g. of I with 15 cc. AcOH and 2.5 cc. Ac_2O for 1 hr., dild. to 50 cc. with AcOH and treatment during 3–4 hrs. at 50–60° with 0.7 cc. Br_2 in 10 cc. AcOH with stirring for an addnl. 4–5 hrs., addn. of 250 cc. H_2O and pptn. of the soln. of the reddish yellow gum in 350 cc. 95% EtOH by pouring into 2450 cc. H_2O gives 5.82 g. of the amorphous *3(α)-aceloxy-11-bromo-12-ketocholanic acid* (II), m. 159° (decompn.). Hydrolysis of 5.82 g. of II by refluxing with 115 cc. of 20% MeOH-KOH, pouring into 1150 cc. ice-H_2O and acidification gave 2.94 g. of 3(α),11-dihydroxy-12-ketocholanic acid (III), m. 205°, $[\alpha]_D^{25}$ 67.1° (1.3% in 95% EtOH) (50% over-all yield from I) (cf. Marker and Lawson, *C. A.* **32**, 5849[6]); CH_2N_2 gives the *Me ester* (IV), of III, m. 157°. III and 98–100% HCO_2H at room temp. for 24 hrs. give the *diformoxy deriv.*, m. 146–8°. Acetylation of III appears to be more complex than reported by M. and L. Refluxing 678 mg. of III with 21 cc. Ac_2O for 1.5 hrs. and soln. of the decompd. reaction product in hot 95% EtOH give 116 mg. of an *anhydride* (V), $C_{26}H_{38}O_6$, m. 268°, $[\alpha]_D^{25}$ 67.2° (0.3% in 95% EtOH); the yield varies from 17 to 32%; V appears to be formed from III by the loss of 1 mole of H_2O and acetylation of 1 HO group; the m. p. is that reported by M. and L. for their 3-acetate; V is either an 11(or 12)-enol lactone or a dimol. anhydride (more likely the latter); boiling V with 33% AcOH for 1 hr. gives a compd., m. 106°, which is considered to be the real *3(α)-acetate* (with 0.5 mol. of H_2O). The mother liquor and washings of V were poured into H_2O, extd. with Et_2O and the Et_2O washed with 5% Na_2CO_3; the acidic product, which did not crystallize, is a *di-Ac deriv.* (VI) of III, which is the only product on acetylation of III in C_5H_5N. Both V and VI yield III on alk. hydrolysis. To establish the position of the Br atom in II, 400 mg. of II and 200 mg. AcONa in 2.5 cc. AcOH were heated at 185–90° for 17 hrs.; repeated pptn. of the Na salt and crystn. from aq. EtOH of the acid gave about 98 mg. of $\Delta^{9,11}$-*3(α)-acetoxy-12-ketocholenic acid*, m. 201°, spectral max. at 241 mμ (ε = 9000). The acid succinate of IV is oxidized by CrO_3 in AcOH to give the *acid succinate of Me 3(α)-hydroxy-11,12-diketocholanate*, m. 194–6°, absorption max. 284 mμ (ε = 135), min. 250 mμ (ε = 80); sapon. did not give a cryst. product. III did not yield a semicarbazone under the many conditions reported (M. and L. report 17% of a compd. m. 232°); a hydrazone or oxime also could not be prepd.; apparently the steric hindrance exerted by the groups on the adjoining C atoms is too great to permit reaction with the 12-CO group. Heating 500 mg. of III with EtONa and $NH_2OH.H_2O$ at 197–200° for 8 hrs. and esterification with succinic anhydride give 78 mg. of the *II succinate*, m. 227° (decompn.), of the *compd.* $C_{24}H_{38}O_3$, m. 162–3°. Apparently the CO group at C_{12} had been eliminated and also the HO at C_{11}.

C. J. West

Sterols. LXXXII. Estrane derivatives. Russell E. Marker and Ewald Rohrmann. *J. Am. Chem. Soc.* **62**, 73–5 (1940); cf. *C. A.* **34**, 1028[7]. (The pp. for part LXXXI should be 3592–3.) –Reduction of estron (I) in acidic EtOH gives 3,17(α)-estranediol (II), m. 205–6°. The mother liquor from II, evapd. and oxidized in AcOH with CrO_3 at room temp. for 2 hrs., gives an oily product which partially sublimes at 80–90° (III) and partially at 125–40° (IV). IV is estranedione (V), m. 144–6° (from dil. Me_2CO) or 179–80° (from Et_2O-pentane); crystn. from dil. Me_2CO again gives the form m. 144–6°. Catalytic reduction of III in 300 cc. abs. EtOH and 3 cc. concd. HCl at 25° and 2 atm. for 5 hrs. gives 17(α)-estranol (VI), m. 105–7°; CrO_3 oxidation did not give a cryst. ketone. V yields a *Br deriv.*, m. 170–2°, which, refluxed with C_5H_5N for 9 hrs., gives *estrenedione* (norandrostenedione), m. 146–8°. Hydrogenation of 5 g. I in 300 cc. abs. EtOH with 0.5 g. Adams catalyst at room temp. and 3 atm. for 18 hrs. gives 4.6 g. of estradiol, m. 173.5°; 17-monoacetate (VII), m. 215–17°. Reduction of VII in AcOH-EtOH with Adams catalyst at room temp. and 10-lb. pressure for 14 hrs. and CrO_3 oxidation in AcOH give a ketone fraction, $C_{18}H_{28}O_2$, m. 102–4°, and VI. The ketone absorbs Br but the product is not cryst. and heating with C_5H_5N does not give a cryst. compd. Thus, cryst. nortestosterone could not be prepd. **LXXXIII. Oxidation products of sarsasapogenin. Studies on the C_{22} lactone.** *Ibid.* 76–8. The 3-keto lactone from sarsasapogenin (I) is catalytically reduced to the *epilactone*, $C_{22}H_{34}O_4$, m. 198–200°; *acetate*, m. 159–60°. The HO lactone (II) is oxidized by CrO_3 in AcOH to the *lactone dibasic acid*, $C_{22}H_{32}O_6$, m. 285–8° (decompn.); *di-Me ester*, m. 170–1°; this acid is also formed by oxidation of sarsasapogenone with HNO_3 in AcOH at 90° for 1 hr. Oxidation of the lactone acetate from I with CrO_3 at 90° for 3 hrs. gives the C_{22} keto acid (III), $C_{22}H_{34}O_4$, m. 285–7°. II and PhMgBr in Et_2O, refluxed for 2 hrs., the residue treated with Ac_2O and C_5H_5N for 18 hrs. at room temp. and the resulting yellow sirup oxidized with CrO_3 in AcOH, give the C_{19} dibasic acid (V), $C_{19}H_{30}O_5$, m. 218–20° (*C. A.* **34**, 4416). The Me ester of III yields an *acetate*, m. 198–9.5°; the *oxime* of III m. 206–8°. After acetylation of III (which yields a noncryst. sirup) CrO_3 does not yield IV. The lactone from III exists in 2 polymorphic forms (m. 188 and 198°), since the two yield the same acetates and upon oxidation give the same 3-keto lactone. **LXXXIV. Progesterone from hyodesoxycholic acid.** Russell E. Marker and John Krueger. *Ibid.* 79–81. 6-Ketocholestanol (25 g.), catalytically reduced with PtO_2 and H in MeOH, gives 20 g. of 3,6-cholestanediol (I), m. 190° (isomeric with that of Windaus, m. 216°); *diacetate* (II), m. 138°. Partial hydrolysis of the 3-Ac group by KOH in MeOH at 20° or by refluxing with $NaHCO_3$ in MeOH and oxidation with CrO_3 in AcOH give *6-acetoxycholestanone*, m. 101°; refluxing with 2% MeOH-KOH for 1.5 hrs. gives *6-hydroxycholestanone* (III), m. 190°. Heating III with $KHSO_4$ at 125–85° gives cholestenone. Hyodesoxycholic acid (IV) forms a *Me ester*, m. 86°. Reaction of the ester from 200 g. IV with PhMgBr, decompn. with HCl and refluxing the diphenyl alc. with Ac_2O for 2 hrs. and with AcOH for 6 hrs., followed by oxidation with CrO_3, give 110 g. of norhyodesoxycholic acid (V), $C_{22}H_{36}O_4$, m.

198°; *Me ester*, with 1 mol. C_6H_6, m. 95°. V (100 g.), treated as above, yields 42 g. of *bisnorhyodesoxycholic acid*, m. 240°; *Me ester* (VI), m. 146°; the intermediate *diphenyl alc.*, m. 222°. VI and 16 moles of PhMgBr, treated as above, followed by acetylation, yield *3,6-diacetoxyetiocholanyl Me ketone*, m. 100°; hydrolysis with MeOH-KOH, oxidation, hydrolysis of the ketone and sublimation from $KHSO_4$ give progesterone. **LXXXV. Oxidation of sarsasapogenin acetate with potassium permanganate.** Russell E. Marker and Ewald Rohrmann. *Ibid.* 222–3.—Sarsasapogenin acetate (I), oxidized with $KMnO_4$ in AcOH at 20°, gives the C_{22} keto acid, the C_{22} lactone and sarsasapogenoic acid. The C_{19} dibasic acid was not found. I is not affected by heating with $KMnO_4$ in a C_5H_5N-aq. Na_2CO_3 medium or with $KMnO_4$ in C_5H_5N alone. **LXXXVI. Desoxotestosterone and its conversion to testosterone.** R. E. Marker, E. L. Wittle and B. F. Tullar. *Ibid.* 223–6.—Oxidation of 230 g. $\Delta^{5,6}$-cholestene dibromide in 500 cc. CCl_4 and 8 l. AcOH at 48–50°, treated with 320 g. CrO_3 in 350 cc. H_2O and 800 cc. AcOH during 4–5 hrs. and stirred 6 hrs. at 50°, gives after a long purification, 5 g. of the *semicarbazone*, m. 285–7°, of *$\Delta^{5,6}$-androsten-17-one* (I), m. 105–7°; reduction of 1.75 g. with Na in PrOH gives 1.4 g. of *$\Delta^{5,6}$-androsten-17-ol* (II), m. 163–5° (*acetate* (III), m. 133 5°). Passing dry HCl through III in $CHCl_3$ at 0° for several hrs. and the product refluxed in EtOH with AcOK for 6 hrs. give a mixt. of II and the 4-isomer (IV), sepd. as the acetates. IV, m. 146 9°; the *acetate* (V) m. 97 100°; the *4-isomer* of I m. 78–80°. Oxidation of V with CrO_3 in AcOH at 50° for 1 hr. gives testosterone, m. 148–50°; if some III is present in the V, there also results 7-keto-$\Delta^{5,6}$-androsten-17-ol acetate, m. 215 17° (cf. Kuwada and Tutihasa, *C. A.* **33**, 8209[2]); the alc. m. 141.5 2.5° (*2,4-dinitrophenylhydrazone*, orange, m. 230–2°). Oxidation of IV with CrO_3 in AcOH gives androstenedione. C. J. West

Molecular rearrangement in the sterols. III. The structure of *i*-cholestanone. Kurt Ladenburg, Purnendu Nath Chakravorty and Everett S. Wallis. *J. Am. Chem. Soc.* **61**, 3483–7(1939); cf. *C. A.* **32**, 2539[6].—Whereas the existence of *i*-cholesterol has been confirmed (*C. A.* **31**, 7879[5]; **32**, 5849[1]), the formulation of the isomer has been questioned. Addnl. expts. are now reported which establish more rigidly the original formula proposed. *i*-Cholestanone (I) (0.25 g.) in AcOH and 2.5 cc. of 34% aq. HBr, allowed to stand overnight at room temp., gives a quant. yield of *α-3-bromocholestan-6-one* (II), m. 123°. Refluxing 4 g. of II in 60 cc. quinoline for 1 hr. in a N atm. gives 79% of *4-cholesten-6-one* (III), m. 104 5° (*oxime*, m. 184–5°); this also results from the α-3-Cl analog of II in somewhat smaller yield. III is considered the true "heterocholestenone," previously reported by Windaus and Dalmer (*C. A.* **13**, 1844), which was shown (*C. A.* **32**, 5849[1]) to be I; the absorption max. of III is at 2450 A., characteristic for conjugation across 2 rings. Refluxing I in AcOH and dil. H_2SO_4 gives the β-3-HO analog of II, m. 142–3° (Windaus, *Ber.* **36**, 3754(1903)); the *oxime* of the Ac deriv. m. 194–5°. I does not contain a double bond, since it is not oxidized by H_2O_2 in AcOH or by neutral or alk. $KMnO_4$. When I is shaken 24 hrs. with KOBr in quinoline there results a quant. yield of *α_1-i-cholestane-6,7-diacid* (IV), $C_{27}H_{44}O_4$, m. 232–3°, $[\alpha]_D^{25}$ 18° (18.1 mg. in 2 cc. Me_2CO); it does not add H_2O, Br or halogen acids nor does it give

an active Liebermann reaction. β-3-Chlorocholestan-6-one (W. and Stein, *Ber.* **37**, 3699(1904)) does not lose HCl with KOH in EtOH; EtONa in EtOH at 120° for 1 hr. gives the *β_2-isomer* (V) of IV, with 1 mol. of H_2O, m. 230–1°, $[\alpha]_D^{25}$ 55° (17.4 mg. in 2 cc. Me_2CO). The isomerism of IV and V can be explained by the relative positions of the groups at C_3 or possibly at C_5. α-3-Chlorocholestane-6,7-diacid (W. and Staden, *C. A.* **15**, 3279) with EtONa in EtOH at 150° for 8 hrs. gives the *α_2-isomer* (VI) of IV, m. 265°, $[\alpha]_D^{25}$ 46° (18.8 mg. in 2 cc. dioxane). The configuration of these acids is discussed. C. J. West

Color reactions of the sterols and steroids, their significance in the investigation of constitutive factors and of problems on the reciprocal action of hormones. G. Woker and I. Antener. *Helv. Chim. Acta* **22**, 1309–28 (1939)(in German); cf. *C. A.* **33**, 1356[9], 4612[6], 6370[6,9].—The color reactions produced by various sterols with completely satd. rings or with a double bond in rings A or B and by steroids with an unsatd. (aromatic) ring A, either alone or in combination with furfural (I), upon underlayering with concd. H_2SO_4 are given in tabular form. Stereoisomerism influences strongly the color reactions of androstanediols and androstanols. Androstan-3-on-17-*cis*-ol (*cis*-dihydrotestosterone) reacts intensively with I + concd. H_2SO_4 and with H_2SO_4 alone, while androstan-3-on-17-*trans*-ol gives with H_2SO_4 no reaction and with I + H_2SO_4 only a faint reaction which develops slowly. The reactions of the androstanediols with I cannot be attributed to a *cis*-OH in the 17-position. In the I + H_2SO_4 reaction a *cis*-OH in the 3-position shows the same auxochrome effect as in the 17-position. If the OH groups in positions 3 and 17 are both in the cis form, the auxochrome effect is at a max.; if both OH groups are in the trans position, the effect is at a min. The conversion of both CHOH groups of the 3,17-androstanediols into CO groups or the presence of only one CO group and absence of OH in the ring system (as in cholestanone and progesterone) is accompanied by inhibition of the color reaction with H_2SO_4 and by reduction in the intensity of the reaction with I + H_2SO_4. But with a double bond in the steroid skeleton, as in Δ^4-androstene-3,17-dione, even the reaction with H_2SO_4 alone becomes pos. The color-producing character is intensified still further, if one or both CO groups are reduced. The behavior of *cis*- and *trans*-testosterones and other derivs. with the double bond in the 4-position show the distinct effect of stereoisomerism, as well as other constitutive factors, on the color and fluorescence. The substitution of a H in the 17-position by the Me group results in an intensification and change of color, as shown by the reactions of the testosterone ring system. The color reactions of 17-methyl-Δ^5-androstene-3-*trans*-17(?)-diol also show the effect of substitution of H, probably in the 17-position, by the Me group. The reactions of the testosterone group compared with those of dehydroandrosterone and of the corresponding *cis*- and *trans*-diols and their substitution products reveal the influence of the position of the double bond. The introduction of a double bond into the bile acids also causes an intensification of the color reactions with I + H_2SO_4 and with H_2SO_4 alone. The reactions of pregnenolone or its acetate show the strong influence of the introduction of the double bond into the ring system of the sterols. The auxochrome action of the OH group in the 3-position is distinct. Expts. on the estrone and estradiol groups likewise reveal the significance of stereoisomerism. The color reactions of mixts. of estradiol (Roche) and ascorbic acid with H_2SO_4 or with I + H_2SO_4 are also tabulated. The color produced with I + H_2SO_4 deepened considerably, if the mixts. had been allowed to stand for 22 hrs. before testing, but was less intense if they had stood for 70–120 hrs. A possible explanation is given. Ruth Berggren

Color reactions of benzaldehyde with sterols and steroids on underlayering with concentrated sulfuric acid. I. Scherrer. *Helv. Chim. Acta* **22**, 1329–40(1939)(in German).—The reactions consisted in underlayering with concd. H_2SO_4 3 cc. alc. soln. of the substance to be tested either alone (under the conditions given by Woker and Antener, *C. A.* **33**, 4612[6], and by S.) or mixed with 0.05–0.2 cc. BzH. The colors produced when these reactions were carried out with hot satd. solns. of cholesterol, ergosterol (fresh cold satd. alc. soln. and the same after 4 months in daylight), sitosterol, stigmasterol, cholic acid, glycocholic acid and 3-acetoxycholenic acid in 96% alc. and by calciferol, desoxycorticosterone acetate, andro-

stane-3-*cis*-17-*cis*-diol, androstane-3-*cis*-17-*trans*-diol, androstane-3-*trans*-17-*cis*-diol, androstane-3-*trans*-17-*trans*-diol, androsterone, isoandrosterone (*cis*) (Ciba), isoandrosterone (*trans*) (Ciba), dihydro-*cis*-testosterone, dihydro-*trans*-testosterone, androstane-3,17-dione, Δ^4-androstene-3,17-dione, dehydroandrosterone (*cis*), dehydroandrosterone (*trans*), testosterone (Hofmann-LaRoche), testosterone (*cis*), testosterone (*trans*), methyltestosterone, Δ^5-androstene-3-*trans*-17-*cis*-diol, Δ^5-androstene-3-*trans*-17-*trans*-diol, 17-methyl-Δ^5-androstene-3-*trans*-17(?)-diol, progesterone, pregnenolone acetate, β-estradiol (*cis*), α-estradiol (*trans*), estrone, equilin and estrin in 70% alc. are given in tables. Ruth Berggren

7-Dehydroepicholesterol. A. Windaus and J. Naggatz. *Ann.* **542**, 204-18(1939).—Marker, *et al.* (*C. A.* **32**, 1866[9]), reported that reduction of ergosterone with (iso-PrO)$_3$Al (I) gave epiergosterol (II); repetition of this work showed that II is not formed but that the product is epialloergosterol (III) (W. and Buchholz, *C. A.* **33**, 4265[8]). Since III has not been obtained in a high state of purity, a study has been made of *7-dehydroepicholesterol* (IV). Epicholesterol is obtained in good yield by reduction of Δ^5-cholestenone with Raney Ni; its acetate (V) (25 g.) in 250 cc. AcOH, treated with 17.5 g. CrO_3 in 25 cc. 50% AcOH during 1 hr. at 50° and allowed to stand an addnl. 3 hrs., gives 18 g. of crude oxidation product. Crystn. from MeOH gives 3.8 g. of *3-cholesten-6-one-3,5-diol 3-acetate* (VI), m. 163°; because it has no characteristic absorption band at 220 mμ, it is not an α,β-unsatd. ketone; it easily loses AcOH (adsorption on Al_2O_3 or standing with 1% MeOH-MeONa), giving 4-cholestene-3,6-dione (VII), m. 123°; *phenylhydrazone*, yellow, m. 272°; both VI and VII give the same disemicarbazone. The mother liquor from V, evapd. to dryness, the residue taken up in 1:1 petr. ether-C_6H_6 and the products adsorbed on Al_2O_3, gives some unchanged V, some cholestenedione and *7-oxoepicholesteryl acetate* (VIII); the latest is probably not pure and m. 119°, absorption max. 234 mμ. Boiling 5 g. VIII and 15 g. I in 500 cc. iso-PrOH for 24 hrs., treating the partly concd. soln. with 300 cc. dil. MeOH-KOH for 1 hr. and pouring into 3 l. cold H_2O, dissolving the ppt. in Et_2O and pptg. with petr. ether give 4 g. of a mixt. of α- (IX) and β-*7-hydroxyepicholesterol* (X); acetylation (Ac_2O and C_5H_5N at room temp. for 1 day), adsorption on Al_2O_3 and fractional elution give as the 1st ext. 1.8 g. of the *diacetate*, m. 165°, $[\alpha]_D^{19}$ 20.2° (19.8 mg. in 2 cc. $CHCl_3$), of IX, m. 172-6°, $[\alpha]_D^{19}$ 38.1° (23.6 mg. in 2 cc. $CHCl_3$); *α-dibenzoate* (XI), m. 154°, $[\alpha]_D^{19}$ 93.7° (28.2 g. in 2 cc. $CHCl_3$). The 2nd fraction of the elution is the *diacetate*, m. 145°, sublimes undecompd. at 180° in a high vacuum, $[\alpha]_D^{19}$ 70.2° (16.8 mg. in 2 cc. $CHCl_3$), of X, m. 173°, $[\alpha]_D^{19}$ 9.1° (22.1 mg. in 2 cc. $CHCl_3$); *β-dibenzoate* (XII), m. 70-80°, $[\alpha]_D^{19}$ 10.7° (14.9 mg. in 2 cc. $CHCl_3$). On heating XI for 1.5 hrs. at 200°, BzOH sublimes at 190° and cholestatriene (XIII) distils over; the distn. residue does not show the absorption spectrum of IV and on recrystn. gives unchanged XI. Heating XII in 50-mg. portions at 195° for 3.5 hrs. gives BzOH, XIII and 14 mg. of the *benzoate* (XIV), m. 118-19°, $[\alpha]_D^{19}$ 48.5° (9.9 mg. in 2 cc. $CHCl_3$), of IV, m. 124-6°, $[\alpha]_D^{19}$ −70.5° (8.8 mg. in 2 cc. $CHCl_3$); XIV also results from XIII on heating in boiling PhNHMe but it is more difficult to purify; the m. p. of IV is not sharp because of H_2O of crystn. IV is not pptd. by digitonin. *Ac deriv.* of IV, m. 114-15°, $[\alpha]_D^{19}$ −35° (1.72 mg. in 2 cc. $CHCl_3$). Ergosterol and IV show the same rate of change on illumination with the Hg-quartz lamp. Illuminated IV has about 0.1 the antirachitic activity of illuminated 7-dehydrocholesterol. C. J. West

Cholesterilene. J. C. Eck and E. W. Hollingsworth. *Iowa State College J. Sci.* **13**, 329-33(1939).—In prepg. cholesterilene by dehydration of cholesterol with $CuSO_4$, the conditions of prepn. were more important than the methods of purification of the product. This method produces a better product than heating cholesterol with Zn dust, but not so pure as by the action of alc. HCl on allocholesterol. 2,4-Cholestadiene was prepd. by dehydrating cholesterol with Al_2O_3 in toluene. Heating of cholesterilene produced a possible peroxide, $C_{27}H_{44}O_3$, which frees I from KI. F. E. Brown

Dehydrocholestenone and its reduction with aluminum isopropylate. A. Windaus and O. Kaufmann. *Ann.* **542**, 218-24(1939).—Dehydrocholesterol (I) (10 g.) in 300 cc. C_6H_6, treated with 20 g. (*tert*-BuO)$_3$Al and 120 g. Me_2CO and refluxed 10 hrs., the product treated with very dil. H_2SO_4 and the C_6H_6 soln. washed with H_2O, gives a brown-yellow oil, which partially crystallizes on standing; *dehydrocholestenone* (II), m. 88°, is isolated by cooling the oil to −80° and washing with petr. ether cooled to that temp.; *semicarbazone*, m. 240° (decompn.); the absorption spectrum indicates an α,β-unsatd. ketone. Boiling 1.6 g. II and 1.5 g. (iso-PrO)$_3$Al in 50 cc. iso-PrOH for 9 hrs. and treating with 25 cc. 8% MeOH-KOH for 0.5 hr. give a yellowish residue which, from the spectrum, contains 16% I and 7% of 7-dehydrocepicholesterol (III); about 50% of the material is pptd. by digitonin (IV); of the portion not pptd. 2.5% is III; thus the reduction of II gives 48.75% of *allodehydrocepicholesterol* (V), 35.25% of *allodehydrocholesterol* (VI), 14.75% of I and 1.25% of III. The reduction product (1.6 g.) and excess of IV in EtOH give 3.2 g. of digitonide (VII), contg. I and VI; decompn. of VII with C_5H_5N and Et_2O and adsorption on SiO_2 gives in the 1st fraction VI, m. 115-16°, $[\alpha]_D^{19}$ 10° (10 mg. in 2 cc. $CHCl_3$); it contains H_2O of crystn. which is difficult to remove completely; *acetate*, m. 109°, $[\alpha]_D^{19}$ −56° (8.2 mg. in 2 cc. $CHCl_3$); *m-dinitrobenzoate*, m. 154° and 180-5°, $[\alpha]_D^{19}$ −78.5° (8.4 mg. in 2 cc. $CHCl_3$). The mother liquor from VII, evapd. to dryness, extd. with Et_2O or petr. ether and adsorbed on SiO_2 gives V, m. 93-4°, $[\alpha]_D^{19}$ 80° (11 mg. in 2 cc. $CHCl_3$); *acetate*, m. 96°, $[\alpha]_D^{19}$ 126.3° (9.5 mg. in 2 cc. $CHCl_3$); *m-dinitrobenzoate*, m. 150° and then 180-5°, $[\alpha]_D^{19}$ 159° (9.4 mg. in 2 cc. $CHCl_3$). C. J. West

Fine Chemicals. Sixty-Three Organic Chemicals. New York: Carbide and Carbon Chemicals Corp.

Catalytic synthesis of hydrocarbons. I. G. Farbenind. A.-G. Fr. 841,030, May 9, 1939. Hydrocarbons with more than one carbon atom or of oxygenated derivatives of hydrocarbons (solid or liquid) are synthesized from CO and H in a liquid medium, using as catalysts agglutinated heavy metals, particularly those of group 8 of the periodic table (Fe is preferred). The agglutinated metals are obtained, either by heating the metals themselves (in powdery state) at 600-1000° in presence of a nonoxidizing gas, such as N, or by heating reducible metallic compds., such as oxides or hydroxides at 600-1000° in presence of a reducing gas, such as H. The addition of Al_2O_3, SiO_2, infusorial earth, compds. of Cu, Ti, Mn, Cr, W, Th, Zr, Ce and other rare earths increases the activity of the catalysts. As the liquid medium, a mineral oil or a tar oil is used. Cf. *C. A.* **33**, 5001[2].

Converting normally gaseous hydrocarbons into products of higher molecular weight. Frederick E. Frey (to Phillips Petroleum Co.). U. S. 2,180,672, Nov. 21. An arrangement of app. is described, and a process which involves passing normally gaseous hydrocarbons such as a mixt. high in CH_4 admixed with oxides of C into contact with a catalytic oxide of Al, Th, Zr or Cr at a temp. of 150-350° to produce hydrocarbons of higher mol. wt.

Catalytic synthesis of aliphatic hydrocarbons. Studien-

und Verwertungs A.-G. Fr. 841,043, May 9, 1939. See U. S. 2,149,515 (*C. A.* 33, 4270[8]).

Isomerization of olefins. N. V. de Bataafsche Petroleum Maatschappij. Fr. 841,004, May 9, 1939. See Brit. 501,896 (*C. A.* 33, 6338[7]).

Cyclization by intramolecular dehydrogenation. Soc. pour l'ind. chim. à Bâle. Fr. 840,970, May 8, 1939. As acceptor of hydrogen, there are used nitrated aromatic compds. which besides the group NO_2 contain at least another negative radical, such as sulfonic, carboxyl, hydroxyl, halogen or a 2nd NO_2. The use of a compd. instead of oxygen as a hydrogen acceptor permits the simplification of the reaction app. Many examples are given, in which the hydrogen acceptors are picric acid, *m*-dinitrobenzene, *m*-nitrobenzenesulfonic acid, nitrochlorobenzene.

Aldehydes of the polyhydrocyclopentanophenanthrene series. Soc. pour l'ind. chim. à Bâle. Fr. 841,058, May 10, 1939. Satd. or unsatd. derivs. of 17-formylpolyhydrocyclopentanophenanthrenes, of the type etiocholane, estrane, hydroestrane or their stereoisomers, are transformed into aldehydes, either by converting the carboxyl group to an acid halide group and reducing the acid halide (protecting, if necessary, the present OH groups by esterification) or by transforming the acid into anilide, converting the anilide by PCl_5 to an imide halide and reducing the latter with $SnCl_2$ and HCl.

Separating and refining lower alkyl amines. Rudolph L. Hasche and Lee G. Davy (to Eastman Kodak Co.). U. S. 2,180,006, Nov. 14. An arrangement of app. is described, and a process for the sepn. and refining of lower alkyl amines, which comprises subjecting a mixt. of primary amines, secondary amines, alc., water and NH_3, to treatment for removing NH_3 by distg. the mixt. at a temp. high enough to drive off the NH_3, treating the mixt. remaining with a nonoxidizing mineral acid which converts the amines to salts, removing at least a part of the alc. from the amine salts by distn., reconverting the amine salts to amines by reaction with an alkali metal hydroxide, and sepg. by distn. the primary amines from the other amines produced.

Ketones. Clayton M. Beamer (to Standard Alcohol Co.). U. S. 2,179,488, Nov. 14. For producing a ketone, such as acetone, a secondary alc., such as iso-Pr alc., is subjected in the form of vapor to the action of Cu coated with ZnO at a temp. range of about 330-400°.

Alkyl esters of 12-ketostearic acid. Henry L. Cox (to Union Carbide and Carbon Corp.). U. S. 2,180,730, Nov. 21. By reaction of 12-ketostearic acid with MeOH, BuOH, etc., (suitably in the presence of H_2SO_4) esters are formed. The Me ester m. 42.5°. The Bu ester m. 56°. These esters are suitable for use in lacquers and plastic compns. as stabilizers and plasticizers with gums and resins.

Aromatic esters. Anthony H. Gleason (to Standard Oil Development Co.). U. S. 2,180,953, Nov. 21. For prepg. an ester such as phenol acetoacetate, an aromatic hydroxy compd. such as phenol is caused to react with a ketene polymer such as diketene in the presence of an inert diluent such as ether and an esterification catalyst such as H_2SO_4.

Basic esters of biphenyleneacetic acid [9-fluorenecarboxylic acid]. Soc. pour l'ind. chim. à Bâle. Fr. 840,824, May 3, 1939. Biphenyleneacetic acid, compds. contg. the radical of the acid, or biphenyleneketene is treated with an amino alcohol, e. g., allylethylaminoethanol, piperidinoethanol, dibutylaminoethanol, diethylaminopropanol, or with a halide or an arylsulfonate of the amino alcohol. The basic esters obtained are watersol. Claim is made to the use of the new compds.

Halogen-containing organic compounds. Heinz Hunsdiecker, Cläre Hunsdiecker and Egon Vogt. U. S. 2,176,181, Oct. 17. A method of producing halogen-contg. org. compds. from org. substances contg. carboxyl groups, in the form of their Hg, Ag or Tl salts, involves the reaction upon the initial salt in the absence of water with Cl or Br in gaseous form, whereby CO_2 and a metal halide split off and a monohalogenated hydrocarbon remains. Details are given of the production of: pentadecyl bromide from Ag palmitate; undecyl bromide from Ag laurate; MeBr from Ag acetate; mixed alkyl bromides from Ag salts of coco oil fatty acids; pentadecylaldehyde hydrobromide from the Ag salt of α-hydroxypalmitic acid; 1,1-dibromoheptadecane from the Ag salt of α-bromostearic acid; 1-bromo-8,9-dichloroheptadecane from the Ag salt of 9,10-dichloroöctadecanoic acid; a product b_{18} 140–4° from Br and Ag sebacate; 9-bromononanoic acid ethyl ester (b_2 118°) from the Ag salt of sebacic acid monoethyl ester; acetyl bromide from Ag pyruvate; benzaldehyde hydrobromide from Ag mandelate; formaldehyde from Hg aminoacetate and Br in CS_2; heptadecyl chloride from Ag stearate; heptyl bromide from mercurous caprylate; pentadecylpyridinium bromide from mercuric palmitate; hexyl chloride and bromide from thallous ethanthate; heptyl bromide from mercuric caprylate; and 1,12-dibromododecane from dodecanedicarboxylic acid.

Making unsaturated organic chlorides, etc. Charles G. Harford (to Arthur D. Little, Inc.). U. S. 2,179,787, Nov. 14. A process for prepg. tertiary unsatd. org. chlorides, and chlorohydrin esters, such as dimethylvinyl chloride, involves treating a tertiary alkyl hypochlorite such as *tert*-Bu hypochlorite and a compd. of the formula YOH in which Y is an acyl radical, such as HOAc, with an org. compd. such as isobutylene having in its mol. 2 C atoms linked by an olefinic double bond, one of these C atoms being in a tertiary position and the other being linked to at least one H atom which is thereby replaced by a Cl atom to give a tertiary unsatd. chloride, in the case of a part of the org. compd., and, in the case of another part of such compd., adding to one of the 2 C atoms an —OY group, and to the other C atom Cl, so that the double bond is transformed into a single bond and a chlorohydrin ester is formed.

Brominating benzanthrone. Melvin A. Perkins and Joseph Deinet (to E. I. du Pont de Nemours & Co.). U. S. 2,180,835, Nov. 21. Bromobenzanthrones are prepd. by treating benzanthrone in an inert org. solvent such as $PhNO_2$ with sufficient Br to give the desired degree of bromination, in the presence of an amt. of sulfuric chloride mol. equiv. to the Br employed (suitably at 80–90°).

Derivatives of aminoarylsulfonamides. Wander Gyógyszerés Tápszergyár R. T. Hung. 122,625, Jan. 2, 1940. Two mols. of the same or different aminoarylsulfonamides are united through *ar*-NH_2 group to CO (phosgene), CS (carbon disulfide), or SO_2. Or, the sulfonamide group is introduced into the product of a previous reaction.

Derivatives of *p*-aminobenzenesulfonamide. Chinoin Gyógyszerés Vegyészeti Termékek Gyára R. T. (Keresztyn és Wolf). Hung. 122,450, Dec. 15, 1939. Carboxylated aliphatic groups (e. g., CH_2COOH) are united to a nitrogen atom of *p*-aminobenzenesulfonamide, either during synthesis or after the formation of the end product. The carboxyl groups may be neutralized by alkalies.

Compounds with active methylene groups. I. G. Farbenind. A.-G. Fr. 840,880, May 5, 1939. These compds. have on the atom of carbon next to the methylene group a chain (straight, branched or interrupted) of at least 9 C atoms. They are obtained by treating the esters and the Na compds. of malonic acid with acid chlorides contg. at least 10 C atoms, and by condensing with N_2H_4 or its derivs. or with primary aromatic amines the esters of acylmalonic acids thus obtained. The reaction is preferably carried out in a neutral solvent such as benzene or xylene. The compds. are particularly important as intermediary coloring products to be incorporated in silver halide emulsions for the production of colored images.

Carbonyl compounds of the cyclopentanopolyhydrophenanthrene series. Karl Miescher, Hans Kägi and Placidus Plattner (to Soc. pour l'ind. chim. à Bâle). U. S. 2,180,762, Nov. 21. For the manuf. of compds. such as testosterone, triarylmethyl ethers of a carbinol compd. of the cyclopentanopolyhydrophenanthrene series

such as those of androstenediol are subjected to thermal decompn.

Metal sulfhydryl compounds from keratin degradation products. Ernst Sturm and Richard Fleischmann (to Firma Johann A. Wülfing). U. S. 2,180,262, Nov. 14. A process for prepg. metal sulfhydryl compds. from keratin degradation products involves reducing the keratin degradation products in aq. soln. with a substance selected from the group consisting of: Na hyposulfite, formaldehyde compounds of Na hyposulfite, alk. earth metal hyposulfite and formaldehyde derivs. of alk. earth metal hyposulfite, under conditions in the neighborhood of neutrality, allowing the mixt. to stand in the absence of air, directly adding to the soln. a water-sol. salt of Cu, As, Sb, Au or Ag in quantity sufficient to saturate the sulfhydryl groups, and sepg. the metal sulfhydryl compds. formed. Various examples with details are given. Cf. *C. A.* **34**, 590[1].

Stabilizing polymerizable vinyl compounds. Sylvia M. Stoesser and Wesley C. Stoesser (to Dow Chemical Co.). U. S. 2,181,102, Nov. 21. Polymerization of a styrene compd. such as styrene or a homolog is inhibited by admixt. with about 0.1–5% of 3-methyl- or 3-phenylpyrocatechol or other pyrocatechol deriv. of the general formula $1,2\text{-}(HO)_2C_6H_{4-n}Y_n$, where Y represents a hydrocarbon radical and n is an integer from 1 to 4.

Thiazoles having a hydrogen atom in the 2-position. Hans Spiegelberg (to Hoffmann-La Roche, Inc.). U. S. 2,179,984, Nov. 14. A process for the manuf. of a thiazole having a H atom in the 2-position, such as 4-methyl-5-hydroxyethylthiazole, involves the reaction of H_2O_2 with a 2-mercaptothiazole, such as 2-mercapto-4-methyl-5-(β-acetoxyethyl)thiazole in concd. HCl soln. at a temp. of about 70° or lower, and adding $BaCl_2$ to ppt. the H_2SO_4 formed.

Treating sludges from reduction of aromatic nitro compounds. Dugald M. Carr and Wm. S. Pilcher (to E. I. du Pont de Nemours & Co.). U. S. 2,179,919, Nov. 14. App. is described, and a process for reducing an aromatic nitro compd. to an aromatic amine by means of iron with subsequent recovery of the excess iron from the resulting sludge involves adding liquid to the sludge to form a slurry, passing the slurry in a continuous stream through a settling chamber permitting the sepn. of the heavier particles upon deflection, abruptly deflecting the stream in a cyclonic path within the chamber, thereby causing the particles of metallic iron therein to settle, and removing the settled particles from the locus of the settling section.

Distilling acetic and similar acids from by-product cellulose esterification liquids, etc. Herbert G. Stone (to Eastman Kodak Co.). U. S. 2,180,021, Nov. 14. An arrangement of app. is described, and a process suitable for the recovery of acetic, propionic or butyric acid which involves (1) distn. in a column from crude aq. acid-liquids contg. suspended and occluded particles of cellulose ester, which would deposit in the column during the distn., (2) substantially continuously feeding a stream of the crude aq. liquid into a tank provided with a peripheral gutter, the tank contg. a large and substantially quiescent vol. of aliphatic acid-liquid, (3) baffling the stream at the point of feed into the tank to avoid disturbing the quiescent vol. of liquid, (4) substantially continuously overflowing the surface layer of the quiescent vol. of liquid into the gutter whereby the velocity of flow of the liquid in the tank is reduced and at least a major part of the particles are deposited in the tank as a sludge, (5) removing sludge from the tank, (6) substantially continuously withdrawing the improved acid-liquid in the gutter through conduit means, and (7) subjecting the improved aliphatic acid-liquid to further treatment including azeotropic distn.

Acetylene recovery from gaseous mixtures. Frederick R. Balcar (to Air Reduction Co.). U. S. 2,180,386, Nov. 21. App. is described, and a method of recovering acetylene from gaseous mixts. which involves bringing the gaseous mixt. into contact with a solvent for acetylene until acetylene has been dissolved therein substantially to the limit of its soly., rectifying the resultant acetylene-contg. liquid with substantially pure gaseous acetylene to free it of impurities more volatile than acetylene, rectifying in a sep. rectification zone the purified acetylene-contg. liquid, boiling the liquid descending through the sep. rectification zone to liberate contained acetylene together with impurities, passing the vapors from the boiling into the sep. rectification zone for use during the rectification therein, sepg. impurities less volatile than acetylene liberated by the boiling at an intermediate level of the sep. rectification zone, and returning a part of the acetylene effluent leaving the sep. rectification zone for use as the acetylene for removing impurities from the liquid formed by bringing the initial gaseous mixt. into contact with the solvent for acetylene.

Separating acetylene from gaseous mixtures. Frederick R. Balcar (to Air Reduction Co.). U. S. 2,180,496, Nov. 21. App. is described, and a process for the sepn. of C_2H_2 from gaseous mixts. in which the gaseous mixt. is brought into contact with a solvent capable of dissolving acetylene selectively from the gaseous mixt. and the solvent contg. dissolved acetylene subsequently is heated to liberate acetylene and the solvent from which the acetylene is liberated is returned for dissolving more acetylene; the process involves heating the gaseous mixt. prior to bringing it into contact with the solvent, scrubbing the acetylene liberated from the solvent and the effluent gas which is not dissolved by the solvent with a liquid absorbent capable of dissolving the solvent and having a higher b. p. than the solvent and sepg. the dissolved solvent from the liquid absorbent by scrubbing the incoming heated gaseous mixt. therewith before sepg. C_2H_2 therefrom.

Recovering ethylene from gaseous mixtures. Joseph L. Schlitt (to Air Reduction Co.). U. S. 2,180,435, Nov. 21. An arrangement of app. is described, and a method of recovering C_2H_4 in substantial purity by rectification from a complex gaseous mixt. also contg. C_3H_6, C_2H_6, CH_4 and H, which involves sepg. a portion contg. substantially all of the C_3H_6 and high-boiling constituents, thereafter sepg. from the remainder at the same pressure a portion contg. substantially all of the CH_4 and other constituents of lower b. p. than C_2H_4, and thereafter sepg. the C_2H_4 from the remaining constituents at a lower pressure.

Separating ethylene from gaseous mixtures. Wm. L. De Baufre. U. S. 2,180,200, Nov. 14. An arrangement of app. is described suitable for sepg. C_2H_4 from gaseous mixts. such as those also contg. H, CO, and CH_4 and which includes a rectifier for sepg. the C_2H_4 from the gaseous mixt., a compressor for compressing the sepd. C_2H_4 to a high pressure, means for throttling a portion of the C_2H_4 from the high pressure and for utilizing the throttled C_2H_4 as a refrigerant to produce liquid reflux in the rectifier. Cf. *C. A.* **33**, 5417[2].

Catalyst for making ethyl chloride. Robert D. Blue (to Dow Chemical Co.). U. S. 2,180,345, Nov. 21. Prepn. of a liquid catalytic medium suitable for use in the production of EtCl from C_2H_4 and HCl involves bringing a chlorinated aliphatic hydrocarbon, such as propylene chloride, into contact with metallic Al in the presence of a relatively small amt. of a halogen-contg. agent such as Br which is reactive with Al under substantially anhyd. conditions and is an activator for the reaction between the chlorinated hydrocarbon and the Al, at a temp. above about 20° (suitably about 50°) but below the b. p. of the chlorinated aliphatic hydrocarbon employed, under the vapor pressure of the reaction mixt. at the temp. employed.

Separation of methanol-acetone mixtures. Albert G. Bright and Webster E. Fisher (to Eastman Kodak Co.). U. S. 2,179,991, Nov. 14. An arrangement of app. is described, and a process which involves charging a column with a MeOH-acetone mixt., vaporizing the mixt. and bringing the vapors into contact with an aq. brine soln. for recovery of acetone at the head of the column and MeOH and brine at the base of the column.

Melamine. Soc. pour l'ind. chim. à Bâle. Fr. 841,022, May 9, 1939. The yield of melamine obtained by heating a soln. of dicyanodiamide in liquid NH_3 at 100° is

greatly increased when the amount of NH_3 is less than sufficient to dissolve all the dicyanodiamide. Thus, when a homogeneous soln. of dicyanodiamide in NH_3 heated for 6 hrs. at 100° gives 30% melamine, a heterogeneous reaction mixt. under the same conditions produces 55% melamine. 1

Melamine. David W. Jayne, Jr. (to American Cyanamid Co.). U. S. 2,180,295, Nov. 14. Dicyanodiamide is heated (suitably to 175–240°) together with ethanolamine or diethanolamine. 2

Trifluoromethyl benzaldehydes. Otto Scherer (to General Aniline Works). U. S. 2,180,772, Nov. 21. Trifluoromethyl-substituted benzaldehydes are produced by heating (suitably to about 80–150°) concd. H_2SO_4 and trifluoromethylbenzal fluorides, *e. g.*, *o*-trifluoromethylbenzal fluoride for the production of *o*-trifluoromethylbenzaldehyde, b_{16} 70° and reacting with Cl to form *o*-trifluoromethylbenzoyl chloride, b_{16} 90°. 4-Chloro-1-trifluoromethyl-2-benzal fluoride b_{18} 82–6°. 4-Chloro-1-trifluoromethyl-2-benzoyl chloride b. 214–17°. 2,5-Bis(trifluoromethyl)benzaldehyde b. 170 2°, and with Cl forms 2,5-bis(trifluoromethyl)benzoyl chloride, b_{10} 69–72°. 3,5-Bis(trifluoromethyl)benzaldehyde, etc., may be similarly produced, and various of the products may be used as *intermediates for the manuf. of dyes, pharmaceutical products, fungicides, insecticides,* etc. 3

Dibenzanthrone and isodibenzanthrone. Melvin A. Perkins (to E. I. du Pont de Nemours & Co.). U. S. 2,180,299, Nov. 14. In purifying these compds., the crude compd. is agitated, at a temp. not exceeding 50° in H_2SO_4 of a concn. such as 94.5–97.5%, in which the compd. is substantially completely but not entirely dissolved, until it is converted into large crystals. 4

1-Hydroxybenzothiazole. Edward M. Van Duzee (to Dow Chemical Co.). U. S. 2,179,987, Nov. 14. 1-Mercaptobenzothiazole is hydrolyzed with an aq. alkali such as NaOH soln. in the presence of an oxidizing agent such as Cl at a temp. of about −10° to 10° and 1-hydroxybenzothiazole is then sepd. directly from the reaction mixt. without acidifying it, as by crystn. 1

Epiallopregnan-3-ol-20-one. Erwin Schwenk, Bradley Whitman and Gerhard A. Fleischer (to Schering Corp.). U. S. 2,180,614, Nov. 21. A method of producing this compd. involves subjecting allopregnanedione to the action of H in the presence of a hydrogenation catalyst such as Pt black acting to limit the reduction substantially to the 3-keto group (suitably in an HOAc soln. contg. HBr). 2

Anthracene. Wm. J. Mattox and Aristid V. Grosse (to Universal Oil Products Co.). U. S. 2,180,814, Nov. 21. Toluene, at a temp. of about 500–700°, is brought into contact with a catalyst comprising essentially activated alumina and an oxide of Cr such as Cr_2O_3. 3

1-Amino-6-chloroanthraquinone. Myron S. Whelen (to E. I. du Pont de Nemours & Co.). U. S. 2,181,034, Nov. 21. In making this compd., 1,6-dichloroanthraquinone is mono-aminated with *p*-toluenesulfonamide. 1

β-Halo-1,3-butadienes. Heinrich Lange and Otto Horn (to I. G. Farbenind. A.-G.). U. S. 2,180,115, Nov. 14. Agents capable of splitting off H halides, such as NaOMe, are caused to react upon a butene dihalogenated in the 1,2-positions in the presence of a boiling org. solvent having a low b. p. such as MeOH, and the butadienes halogenated in the 2-position are eliminated as formed by the vapors of the solvent. Cf. *C. A.* **32**, 3203[6]. 4

ARTHUR W. DOX

Pathological serum proteins. (A contribution to the significance of the Takata test and the relation of the liver to serum protein production.) Hans Kaunitz, Gonzalo F. Austria and Fortunio Sales. *Acta Med. Philippina* **1**, 53–68(1939); cf. *C. A.* **30**, 3055[7]. In certain clinical conditions the definite variations in ultraviolet absorption, especially of the globulins, can be explained only by physicochem. disturbances in the protein structure (Fuchs, K. and Lerch, *Z. klin. Med.* **128**, 332–42 (1935)). Certain deviations in serum viscosity are also attributed to structural alterations in the proteins, as well as to disturbances in their quant. distribution (K. and Kent, *Ibid.* **132**, 670–88(1937)). These and other similar disturbances are found chiefly in parenchymatous liver diseases. The decrease in the serum proteins, fibrinopenia and globulinemia in some liver diseases result from damage to the liver tissue. The liver is considered one of the main organs involved in serum-protein production. This has been confirmed chemically. Changes in the permeability of the blood capillaries and tissue cells at the onset of the disturbances are of pathogenic significance for the understanding of the early deviations from the normal serum protein picture. Pos. reactions in the Takata and certain other tests are attributed especially to qual. abnormalities of the serum proteins. The increase in the mol. wt. of the proteins (globulinemia) favors a decrease in serum stability. Changes in mol. size and physicochem. structure are the chief factors influencing the results of the Takata test. A pos. Takata test is usually accompanied by an increase in serum viscosity. Since the stability of the serum is largely dependent on the liver function, it is not surprising that many serum-instability reactions (e. g., the Takata test) are pos. in some parenchymatous diseases of the liver. The Takata test was studied in 241 cases. In 24 cases of Laennec's cirrhosis with ascites 22 gave pos. results. Of the remaining 217 cases 21 gave a pos. reaction. Nearly all of these 21 pos. cases had liver damage and hopeless diseases. If a disease has led to a disturbance in serum stability, the prognosis is bad. Edema, mostly ascites, occurred in ¾ of the pos. cases. Any modification in serum stability decreases the capacity of the serum to attract tissue fluid; this may result in the development of edema, especially if other factors, as vascular obstruction, are operating simultaneously. Other causes, however, also play a part in the development of edema. Cf. *C. A.* **30**, 3055[7]. Ruth Berggren 6

Plankton studies. II. The western North Atlantic, May–June, 1939. Gordon A. Riley. *J. Marine Research, Sears Foundation Marine Research* **2**, 145–62 (1939).—Temp., O, plant pigments, phosphate and nitrate were measured at 18 stations between the northern coast of Cuba and Woods Hole. In the surface waters of all stations the chlorophyll content was detd., and the O and nitrate production and consumption were estd. in exptl. light and dark bottles. The quantity of plant pigments at the 4 northernmost stations was greatest at the surface; the max. depth of occurrence was 100 m. or less. At the southern stations they occurred to a depth of 300–400 m. or more; the max. observed values were at 100 m. In the northern and in the tropical waters the mean quantity of plant pigments in the surface waters was 4100 and 1300 Harvey units/cu. m., resp., and the mean chlorophyll content was 2.1 and 1.0 mg./cu. m., resp. But the total crop in the entire vertical column was considerably greater in the southern waters. The mean O_2 production in the northern waters was 0.180 mg./l./day or about half the values that had been previously reported for temperate shallow-water regions during the spring bloom; in the tropical waters the mean was 0.091 mg. Differences in the quantity of the standing crop account for 55% of the variations in O_2 production. Other factors (temp., light, nutrients) apparently have no significant effect. Although the gross productivity (glucose production) of the southern surface waters is only half as great as in the north, it is suggested that because of the 7 8 9

greater transparency of the water, the max. depth of the photosynthesis is about 3 times as great, and the total productivity per unit area may be equal to or greater than that of temperate regions. Nitrate consumption was relatively much smaller than O_2 production; rough estimates indicate that only 10–27% of the glucose produced was transformed into nitrogenous material during the expts. The theoretical biol. implications of this phenomenon are discussed. Quant. measurements of zoöplankton were made at 5 stations. The total no. of animals was smaller in the tropical waters than at the northern stations but was approx. equal to the annual mean for certain other temperate regions, the English Channel and the North Sea, as well as the tropical waters of the Great Barrier Reef lagoon. Ruth Berggren

The biology of high-frequency perfusion. Schliephake. *Strahlentherapie* **66**, 296–302(1939); cf. *C. A.* **29**, 4032[5]; **33**, 1774[2].—A short review on the effect of irradiation with short waves on tissue chemistry is included. Ruth Berggren

The behavior of the plasma phosphatase and of the bone mineral content in animals treated with bone phosphatase. Ignazio Scimone. *Pathologica* **31**, 520–5(1939).—By intravenous injection of an aq. ext. of bone tissue, an increase of the plasma phosphatasic activity was observed. This increase is variable, reaching its max. 5–10 min. after the injection and disappearing in several hrs. G. A. Bravo

Carboxyl and amino groups of bilirubin. W. L. Dulière. *Bull. soc. chim. biol.* **21**, 1181–4(1939).—Results of attempts to det. the no. of carboxyl and amino groups were inconclusive L. E. Gilson

Inhibiting action of dihydroxymaleic acid on catechol oxidase. Marcel Florkin and G. Duchateau-Bosson. *Bull. soc. chim. biol.* **21**, 1204–7(1939).—At pH 7.3 dihydroxymaleic acid in concns. of 0.002 *M* or more inhibits the action of catechol oxidase. Ascorbic acid has no such action. L. E. Gilson

Physiological role of bile salts. Influence of bile salts on the passage of fat acids through dialyzing membranes. M. A. Macheboeuf and R. Perrimond-Trouchet. *Compt. rend. soc. biol.* **132**, 274–6(1939).—The sol. compds. formed from higher fat acids and glycocholic acid at pH 6.3 do not diffuse through collodion membranes. L. E. Gilson

The effect of stream conditions on lake plankton. Charles B. Reif. *Trans. Am. Microscop. Soc.* **58**, 398–403(1939).—The chem. conditions, temp. and pollution had no marked effect in causing a decrease of plankton in streams studied. L. Wilson Greene

Modification of the cortical frequency spectrum by changes in CO_2, blood sugar and O_2. F. A. Gibbs, Denis Williams and E. L. Gibbs. *J. Neurophysiol.* **3**, 49–58(1940).—The responses of the elec. activity of the normal cortex of men to alterations in normal blood constituents have been analyzed with the Grass frequency analyzer. Decrease or increase in CO_2 content in the internal jugular blood is assocd. with a shift in energy distribution in the cortical frequency spectrum toward the slow or fast side, resp. O_2 and glucose can be varied within wide limits with little change in the cortical frequency spectrum, but when the O_2 satn. or glucose concn. in the internal jugular falls to a critically low level, there is a sudden shift of energy distribution to the slow side. With exceedingly high concns. of glucose, the energy distribution shifts to the fast side. Expts. on rabbits indicate that the effects of high O_2 tension are similar to those of high glucose concns. The results suggest that the elec. activity of the cortex is a manifestation of the activity of a great no. of chem. oscillators having different natural periods but responding similarly to any given factor. Marion Horn

Study of blood serum proteins by electrophoresis. E. Jameson and C. Alvarez-Tostado. *J. Phys. Chem.* **43**, 1165–72(1939).—Salting-out and electrophoretic expts. are used to study changes in the blood serum proteins of the adult of one species as brought about by the ingestion of colostrum from an animal of a different species. The results of the salting-out expts. are plotted on several triangular phase-rule diagrams. Changes in rat and human serums are shown to take place after feeding cows colostrum. The α-fraction is greatly increased, while the γ-fraction is either split or a new fraction appears. Similar changes are shown to occur in highly immune rat serum. L. Kolodny

Chemistry of the van den Bergh reaction. Thomas B. Coolidge. *J. Biol. Chem.* **132**, 119–27(1940).—All of the bilirubin of plasma in jaundice is bound to the plasma albumin. The plasma bilirubin which gives a direct van den Bergh reaction in 10 min., when the procedure of Malloy and Evelyn (*C. A.* **31**, 7080[8]) is used, is attached to the plasma albumin as a dissociable complex. That which does not give a direct reaction is probably attached by a valence bond to a fraction of the plasma albumin pptd. by $(NH_4)_2SO_4$ between 61 and 72.5% satn. at pH 6.8. The role of MeOH in causing all the bilirubin to react is purely catalytic. The character of the van den Bergh reaction cannot be correlated with the concn. of cholic acid in the plasma. A. P. Lothrop

The preparation of a concentrated fecal phosphatase and its effect on dogs and rats. Yen Ping Chen, Smith Freeman and A. C. Ivy. *J. Biol. Chem.* **132**, 445–54(1940); cf. *C. A.* **32**, 3432[7].—A simple method is described for the prepn. of phosphatase from dog feces which gives a less toxic and enzymically more potent product than is obtained by methods previously proposed. It increased the serum phosphatase in dogs for at least 48 hrs. when injected intravenously. The prepn. was quite stable and showed no significant change in potency after several months storage. After intravenous injection into dogs, no changes occurred in the serum or urine Ca or inorg. P which could be unquestionably ascribed to the activity of the enzyme. However the serum sugar decreased 20 mg. or more in 8 out of 10 anesthetized dogs receiving the active prepn. An elevation of the serum phosphatase was maintained for 1 month in growing rats by the daily intraperitoneal injection of the enzyme prepn. No significant difference in the growth or well being could be noticed between groups receiving the active or inactivated prepns. although the group receiving the active prepn. had a higher av. serum phosphatase. A. P. Lothrop

Factors influencing microbial thermogenesis. Stanley E. Wedberg and Leo F. Rettger. *J. Bact.* **39**, 23(1940).—There is a correlation between maximal growth temp. and maximal heating temp. The minimal destruction temp. of such enzyme systems as indophenol oxidase and succinodehydrogenase appeared to bear a definite relation to the maximal growth temp. Catalase destruction could not be correlated. Peroxidase was heat-stable. John T. Myers

The use of radioactive elements as tracers in physiology. H. R. Crane. *Phys. Rev.* **56**, 1243–4(1939).—Reply to Barnett (*C. A.* **34**, 783[3]). The min. amt. of radioactivity which will affect cell permeability is about 10^6 disintegrations per cc. per sec.: tracer elements are not ordinarily used in such high concns. The possibility of biol. material discriminating between radioactive and stable isotopes is discussed. G. M. Petty

Radioactive isotopes in biology. Lorin J. Mullins. *Phys. Rev.* **56**, 1244(1939).—Reply to Barnett (*C. A.* **34**, 783[3]). Doses below 1 millicurie per l. of radioactive Na are without effect on the uptake of Na by cells. Concns. above 1 millicurie/l. have an effect. It is necessary to establish a limiting value for each radiation. G. M. Petty

Chemical studies on moccasin venom. II. Dialysis and attempts at fractionation of the hemorrhagic and hemolytic components. Samuel M. Peck and Walter Marx. *J. Mt. Sinai Hosp., N. Y.* **6**, 271–8(1940); cf. *C. A.* **31**, 8010[3].—Native moccasin venom consists largely of proteins and related substances. The pseudocryst. crude venom showed 14% N. In 2% soln., it gave pos. biuret and xanthoproteic reactions, was coagulated by heat, and was pptd. by tannic acid, CCl_3CO_2H, alc., acetone and by 0.3–0.6 satn. with $(NH_4)_2SO_4$. About one-half of its dry wt. was not dialyzable through cello-

phane. The content of carbohydrates and lipoids was very small. Hemorrhagin and hemolysin were assocd. with protein fractions, were practically nondialyzable through cellophane, and were pptd. by alc., acetone or $(NH_4)_2SO_4$ at 0.3–0.6 satn. The antihemorrhagic principle was found, partially purified, in the dialyzed supernatant liquid of a native venom soln. pptd. at 0.8 satn. with $(NH_4)_2SO_4$. It was free of hemolysin and contained very little hemorrhagin. J. Pinchack

Report on Ninth International Congress of Military Medicine and Pharmacy, Bucharest, Rumania (1937). Wm. S. Bainbridge. George Banta Publishing Co., Menasha, Wis.—A detailed report on the medical and pharmaceutical problems which arise during conflict. Detailed methods are given for the treatment of gassed wounded persons. A comparative study was made of the supply of foodstuffs and the alimentation of the sick and wounded in times of peace and war. Colorimetric analytical methods used in military hospitals are also discussed. H. J. P.

Determination of peroxidase activity in the presence of catalase. A. A. Kul'tyugin and P. S. Kanashenok. *Biokhimiya* 4, 133–8(1939).—The catalase activity on H_2O_2 is completely inhibited in the presence of *M* $NaNO_3$, whereas the peroxidase activity remains unchanged. H. Priestley

Are tyrosine and tryptophan produced in the enzymic decomposition of blood proteins by trypsin? A. I. Paradashvilli and N. I. Gavrilov. *Biokhimiya* 4, 139–41 (1939).—The general view is that tyrosine and tryptophan, of all amino acids, are the most easily detached from proteins by enzymic action. Expts. do not bear this out. After fermentation of the blood by trypsin, the phosphotungstic acid filtrate gave neg. colorimetric tests for tryptophan and tyrosine. H. Priestley

The reaction capacity of physiologically important substances in mixtures. II. The reaction capacity of acetone in the presence of glycine. A. M. Kuzin and N. A Nevraeva. *Biokhimiya* 4, 142–8(1939); cf. *C. A.* **33**, 650[4].—Addnl. proof that carbonyl compds. are activated by amino acids is shown by the fact that acetone, in the presence of glycine, reacts much more rapidly with I, $NaHSO_3$ and furfural. **III. Reaction of simple sugars in the presence of glycine.** A. M. Kuzin and Z. Makaeva. *Ibid.* 367–72.—Small amts. of glycine accelerate the reduction by glucose of Fehling soln. Larger amts. retard reduction and in a satd. soln. of glycine or other amino acid completely inhibit the reduction. Addn. of 0.7% glycine to Barfoed's reagent will completely prevent reduction by glucose. No reduction by glucose of Ag_2O, picric acid and Indigo Blue will occur when glycine is added to the soln. H. Priestley

Fermentability of the simplest diketopiperazines. E. D. Stakheeva-Kaverzneva and N. I. Gavrilov. *Biokhimya* 4, 154–9(1939).—Neg. results were previously obtained both by Abderhalden (cf. *C. A.* **21**, 1966; **27**, 93) and by Waldschmidt-Leitz, *et al.*, (cf. *C. A.* **22**, 3419) on the fermentation of simple diketopiperazines. When treated with aniline at 180°, simple diketopiperazines are rendered more labile to trypsinkinase. Glycyl leucine is hydrolyzed in 96 hrs. to the extent of 20% by trypsinkinase. Trypsin and erepsin cannot hydrolyze such diketopiperazines. H. Priestley

Mechanism of amylase activation by neutral salts. Ya. P. Barmenkov. *Biokhimiya* 4, 160–7(1939).—Previous measurements of the elec. charge on amylase did not take into account the presence of mucin, which carries an electroneg. charge. Free amylase is electropos. The mucin-amylase complex may be predominantly electroneg., and will migrate to the pos. pole; this gives the impression that amylase itself is electroneg. NaCl will break up the adsorption mucin-amylase complex and will cause the amylase to migrate to the cathode. H. Priestley

Formation and breakdown of amino acids by intermolecular transfer of amino groups. VI. Metabolism of *l*-(−)-aspartic acid in different animal tissues. M. K. Karyagina. *Biokhimiya* 4, 168–83(1939); cf. *C. A.* **33**, 2916[5,6].—Besides glutamic acid, the other dicarboxylic amino acid, *l*-(−)-aspartic acid, is also capable of intermol. transfer of amino groups to pyruvic acid, to form alanine. Two different enzyme systems appear to be involved in the aspartic and glutamic acid transformations. The transfer of aspartic acid was observed in skeletal and cardiac muscles, in liver, kidney and brain tissue, but not in testicular tissue. **VII. Amino-nitrogen transfer in the animal body.** M. G. Kritsman. *Ibid.* 184–8.—The process of amino-N transfer takes place not only in chopped-up isolated tissues, but also in the live animal body, whose blood, though itself unable to effect the transfer, still contains the transformation products. Intravenous, intramuscular or intraperitoneal injection of glutamic acid into rabbits, pigeons or white mice causes the rapid appearance of alanine in the blood and tissues. The pyruvic acid is supplied from endogenous sources. Injection of a mixt. of alanine and α-ketoglutaric acid leads to the formation of glutamic acid. **VIII. Amino-nitrogen transfer by α-aminomonocarboxylic acids carrying a second acid group: Cysteic acid and phosphoserine.** S. M. Bychkov. *Ibid.* 189–201.—A monocarboxylic acid carrying a second acidic group, such as $-SO_3H$ or $-OPO_3H_2$, also acts as a donor of amino groups, like dicarboxylic acids (glutamic and aspartic acids). The enzyme prepn. catalyzing the reversible amino-N transfer from and to glutamic acid (cf. K., *C. A.* **33**, 2916[6]), is inactive with aspartic acid, cysteic acid and phosphoserine. Cysteic acid and phosphoserine, unlike dicarboxylic amino and ketoacids, do not catalyze the amino-N transfer between 2 monocarboxylic acids, e. g., lysine and pyruvic acid. **X. Catalytic function of dicarboxylic amino and keto acids in amino-nitrogen transfer between monocarboxylic substrates.** A. E. Braunshtein and M. G. Kritsman. *Ibid.* 303–15.—It has previously been detd. that no amino-N transfer occurs between monocarboxylic acids. The presence of minute amts. (as low as *M*/16,000) of an amino or keto dicarboxylic acid will catalyze such a transfer between monocarboxylic acids. Citric, succinic, fumaric and malic acids will also act as catalysts under aerobic conditions, since they are precursors of α-ketodicarboxylic acids. H. Priestley

Invertase differences in melons. V. V. Arasimovich. *Biokhimiya* 4, 251–9(1939); cf. *C. A.* **33**, 7832[4].—In some types of Central Asian melons, invertase shows only hydrolytic activity, with synthetic activity completely absent, whereas in other types, the invertase can only synthesize but not hydrolyze. H. Priestley

Peroxidase oxidation of amino acids. Ya. A. Babin. *Biokhimiya* 4, 392–403(1939).—Exts. of various organs and tissues (notably the kidneys) can deaminate amino acids in the presence of H_2O_2. The peroxidase deamination is lost when the tissues are previously heated to boiling. Plant peroxidases from horseradish and milk, as well as the pseudo-peroxidase cytochrome c, can also deaminate amino acids. H. Priestley

Two stages of proteolytic breakdown of gelatin. M. S. Reznichenko, N. P. Koz'mina and P. I. Starosel'skii. *Biokhimiya* 4, 434–44(1939); cf. Reznichenko and Poptsova, *C. A.* **33**, 2917[1].—During the first 20–30-min. action of pancreatin on gelatin, no increase of amino N was observed; but owing to the disaggregating effect of the enzyme, the viscosity dropped to 25% of the original value, and 60–80% of the total protein was no longer pptd. by CCl_3CO_2H. H. Priestley

Comparative study of the properties of enzymes synthesizing carbon chains: carboligase and aldolase. A. M. Kuzin and E. V. Sukhareva-Budnitskaya. *Biokhimiya* 4, 445–8(1939).—Carboligase and aldolase are not identical. Carboligase is inactivated by dialysis and by heating to 50°, whereas the activity of aldolase remains unchanged. H. Priestley

Mechanism of sugar synthesis from products of glucolysis. I. Oxidation of pyruvic acid in the presence of glycine. A. M. Kuzin and Z. Makaeva. *Biokhimiya* 4, 449–56(1939).—The oxidation of pyruvic acid to hydroxypyruvic acid, which has often been postulated in enzymic reactions, has been accomplished experimentally. The *p*-nitrophenylhydrazone of hydroxypyruvic acid was

isolated from the reaction mixt. of pyruvic acid, glycine and I. H. Priestley

Comparative effects of acenaphthene in plants and of carcinogenic compounds upon animal tissues. A. A. Shmuk, A. Guseva and G. Il'in. *Biokhimiya* 4, 470–82 (1939); cf. *C. A.* 33, 7848[7].—Acenaphthene interferes with the metabolic processes of wheat sprouts. Respiration is reduced, and the sap is more acid, presumably through the formation of free H_3PO_4 from nucleoproteins. The glucolytic action is twice as intense as in normal sprouts. More N is accumulated, and a change is observed in the mineral constituents of the plant. Acenaphthene acts on plants in the same manner as carcinogenic compds. do on animals. H. Priestley

Free hydroxyl groups of proteins and their importance for the proteolysis by tryptic enzymes. A. Kizel and T. Evreinova. *Biokhimiya* 4, 492–7(1939).—The Millon reaction for tyrosine is not given by acetylated gliadin. Pepsin readily acts on acetylated gliadin, but pancreatin and papain are completely without effect. H. P.

Biochemistry and experimental morphology. Joseph Needham. *Chem. Products* 3, 9–14(1939).—A discussion of chem. implantation, organizers in adult tissue, difficulties of implantation, microchemistry and metabolism, anaerobic and aerobic glucolysis, oxidation-reduction in tissue, importance of organizers and nexus of biology and physiochemistry. Leopold Scheflan

Immunochemistry of catalase. II. Activity in multilayers. William D. Harkins, Lyman Fourt and Priscilla Chinn Fourt. *J. Biol. Chem.* 132, 111–18(1940); cf. *C. A.* 33, 7325[8].—The enzymic activity of catalase alternating with anticatalase on a conditioned multilayer plate (Blodgett-Langmuir-Porter multilayers) was studied. Catalase covered by anticatalase is only slightly less active than exposed adsorbed catalase. The activity per g. is about 0.1 to 0.2 of that in soln. The total activity does not increase with 2 layers of catalase on the plates, suggesting failure of the substrate to get past the first active layer. The activity of catalase layers picked up after spreading at the air-H_2O interface runs through the same range as that of layers deposited from soln. On exposure of plates to a reaction mixt. some enzyme is liberated into the soln. when the outermost layer is catalase, while an outer layer of anticatalase permits almost no loss of activity into the soln. D. S. Searle

Activation energy of urea hydrolysis catalyzed by soybean urease. Irwin W. Sizer. *J. Biol. Chem.* 132, 209–18(1940).—The hydrolysis of urea catalyzed by soybean urease was studied as a function of temp. between 0.2 and 50°. At all temps. CO_2 liberation was a linear function of elapsed time. The data are in accord with the Arrhenius equation in which the energy of activation is either 8700 or 11,700 cal. per g. mol. depending on the compn. of the digest. With certain enzyme prepns. the activation energy was 11,700 cal. below and 8700 cal. above a crit. temp. The activation energies of the urease–urea system were identical for extd. and purified soybean and jack bean urease and for unextd. urease still present in the soybean or jack bean. D. S. Searle

Factors affecting the activity of carbonic anhydrase. Manfred Kiese and A. Baird Hastings. *J. Biol. Chem.* 132, 281–92(1940).—The purification of carbonic anhydrase obtained from washed beef erythrocytes is described. Hydration of CO_2 and dehydration of H_2CO_3 are influenced equally by the enzyme. The enzyme activity may be inhibited by certain oxidizing agents ($KMnO_4$, I_2, periodate, perchlorate, chlorate, persulfate, bromate) and the activity restored by certain reducing agents (ascorbic acid, cysteine, hydroquinone). The effect of inhibitors was the same on both the hydration and dehydration activity. The enzyme activity was studied between pH 6.1 and 10.1. The rate of hydration was optimal at pH 8.1. CO at pressures up to 1200 mm. Hg did not inhibit the enzyme activity. Sulfide and cyanide strongly inhibited the enzyme. D. S. Searle

Electrokinetic aspects of surface chemistry. VI. Interaction of gelatin with casein and egg albumin at surfaces. Laurence S. Moyer and Elsie Z. Moyer. *J. Biol. Chem.* 132, 357–71(1940); cf. *C. A.* 32, 5419[6].—The mechanism of film formation on surfaces of particles in protein solns. was studied by means of electrophoresis measurements. When collodion particles coated with gelatin or egg albumin were placed in contact with a soln. of egg albumin or gelatin, resp., the particles assumed a gelatin surface in respect to their elec. mobilities. C, quartz, collodion or mineral oil particles in a mixt. of egg albumin and gelatin, and quartz particles in a mixt. of surface-denatured egg albumin and gelatin were likewise coated with gelatin. In the casein–gelatin system at pH 5.8–7.8 the resultant surface was detd. by the protein with which the particles were first coated. In a casein-gelatin mixt. the casein diffused more rapidly to the surface of quartz or collodion particles and largely prevented the adsorption of gelatin. Insol. casein particles were not influenced much by gelatin except between pH 5.2 and 3.7, in which range they were completely coated with gelatin. The mechanisms involved in the interaction of these proteins and their biol. significance are discussed. **VII. Electrophoretic behavior of microscopic particles in the presence of horse, human or rabbit serum.** *Ibid.* 373–86.—Quartz particles in horse serum probably adsorb an albumin component (Kekwick's albumin A), while collodion and mineral oil particles appear to adsorb a globulin (possibly Tiselius' globulin α (*C. A.* 32, 1728[8])). No trace of albumin B was found by exposing particles to serum, and it is possible that the colorless albumin B is to some extent a lab. product. Quartz and collodion particles in dil. rabbit serum show no significant differences in mobility when acetate buffer is used, but do in phosphate buffer. In dil. human serum quartz and collodion particles had identical mobilities between pH 4 and 5.8, but divergent mobilities above pH 5.8. Probably the quartz is coated with albumin and the collodion with globulin α. The common isoelec. point of these particles (pH 4.9) agrees with that found for the surfaces of the chylomicron emulsion in blood by Ludlum, Taft and Nugent (cf. *C. A.* 25, 1540). D. S. Searle

Photodynamic effect on oral mucosa. Tinkyoku Hai. *J. Chosen Med. Assoc.* 29, 2120–32(German abstr. 138–9)(1939).—An exposure of oral mucosa of rabbit to sunlight or C arc lamp produces no ill effect, but a similar exposure after an injection of 0.5 cc. per kg. body wt. of 0.5% trypaflavine causes local congestion, erosion and ulceration of mucosa after 24 hrs. This photodynamic effect becomes more pronounced if India ink is injected in an amt. stimulating to the reticulo-endothelial system (*R*), and becomes far less than normal if *R* is blocked by the ink. In the serum of the normal animal there is a very small but definite amt. of a substance which influences the photodynamic effect on the tissue. The amt. of this substance can be increased by stimulation of *R* without spleen. S. Tashiro

Hung-chü. I. Enzymic activities of Hung-chü. Hisieh Chiu Taoh. *J. Oriental Med.* 31, 741–9(English abstr. 50–2)(1939).—Both com. and pure strains of Hung-chü, *Monascus purpureus* Went (reddish yeast used for brewing Hung-chü, red wine), show the presence of amylase, glycolase, invertase, pepsin, trypsin, erepsin, lipase, reductase, catalase and glycerophosphatase, but no lecithinase. S. Tashiro

Amine oxidase and adrenaline. D. Richter and A. H. Tingey. *J. Physiol.* 97, 265–71(1939); cf. *C. A.* 33, 2589[9].—The rate of inactivation of adrenaline by amine oxidase has been measured at adrenaline concns. down to 10^{-7}. The degree of inhibition of amine oxidase by ephedrine was measured with 10^{-7} adrenaline as substrate. The amine oxidase concn. in the livers of a no. of animals was detd. Calcns. based on these measurements do not support the view that the amine oxidase is specifically concerned in the inactivation of sympathin or adrenaline. E. D. Walter

B—METHODS AND APPARATUS

GLENN E. CULLEN

New application of kinetic colorimetry to the study and to the estimation of D vitamins and provitamins. Yves Raoul and Paul Meunier. *Compt. rend.* **209**, 546–8 (1939).—The reagent $SbCl_3$ in Ac_2O gives a max. intensity of color with calciferol in 45–60 secs., with ergosterol and lumisterol in 7–8 mins., and with cholesterol after a much longer period. These results are confused by mixts. and by the presence of vitamin A. A mixt. of the Carr-Price and Liebermann reagents has been devised to overcome these difficulties and consists of 30 cc. of $CHCl_3$ satd. with $SbCl_3$, 3 cc. Ac_2O and 5 drops of concd. H_2SO_4. The observation cell of the electrophotometer is charged with 3.5 cc. of this freshly prepd. reagent and 0.5 cc. of $CHCl_3$ contg. 50 γ of the sterol under investigation. The absorption is measured after 30 secs. through the blue screen, no. 30, and is followed for 4–5 mins. to permit graphical representation. The reaction develops slowly with cholesterol (with 1 double link) but with lumisterol, ergosterol and 7,8-dehydrocholesterol (contg. 2 conjugated double linkages) a definite intensity is immediately established which maintains a const. value. The primarily high intensity of compds. with 3 conjugated double linkages (vitamins D_2 and D_3) diminishes rapidly and reaches a const. level. Thus this kinetic colorimetry enables the estn. of the linkages in ring B of a sterol to be made. It is also possible to use the method for the detn. of compds. with antirachitic action, since it eliminates the interference of sterols with trans configuration. C. R. Addinall

Determination of nicotinamide in animal organs. P. Karrer and H. Keller. *Helv. Chim. Acta* **22**, 1292–3 (1939); cf. *C. A.* **33**, 1356[3].—An improved method for the extn. and detn. of nicotinamide (I) in animal organs is given. The finely divided material is thrice boiled out for 30 mins. with 3 vols. H_2O and the combined exts. are freed from fatty residues by shaking out 2 or 3 times with Et_2O. The aq. ext. is acidified with H_2SO_4 until 0.1 *N*, the liquor is boiled gently for 30 mins. and neutralized with $Ba(OH)_2$. The filtrate is concd. to 50–100 cc. and extd. *in vacuo* for 5–6 hrs. with BuOH. The I remaining after evapn. of the BuOH ext. is returned to the extd. residue which is then extd. twice by boiling H_2O. The aq. ext. is evapd. to dryness *in vacuo*, taken up in abs. MeOH and dry benzene, filtered and again evapd. to dryness *in vacuo*. The residue (1 part) is dissolved in MeOH contg. 3 parts by wt. of $(O_2N)_2C_6H_3Cl$ and the MeOH is distd. off. The dry mixt. is melted on the steam bath for 30 mins., taken up in 80% alc., made up to a definite vol. and, after addn. of a few drops of 10% alc. KOH, colorimetrically detd. in a step photometer. Muscle of rats, horses and cattle yielded 50.8, 46.6 and 38.3; horse and cattle livers 160.0 and 93.0; cattle kidneys 190.4; and baker's yeast 120.0 γ per g. C. R. Addinall

New method of determining coproporphyrin. Geneviève Glotz. *Compt. rend. soc. biol.* **132**, 194–5(1939).—Coproporphyrin, dissolved in 5% aq. HCl, shows a marked ultraviolet absorption band at 401 mμ. Concns. of 0.06–3.3 mg. % can be accurately detd. by means of the Zeiss spectrograph. L. E. Gilson

Chemical methods for the determination of vitamin C. A. A. Kolesnik. *Nauch. Zapiski Inst. Narodnogo Khoz. im. Plekhanova* **1938**, No. 1, 107–13; *Khim. Referat. Zhur.* **2**, No. 4, 80(1939); cf. *C. A.* **33**, 2602[7].—A review of different modifications of the detn. of vitamin C according to the method of Tillmans: Eckelen and Emmerie (*C. A.* **32**, 2558[1]), Bukin and Devyatkin modifications. The modification proposed by K. requires a cold extn. of the finely pulverized sample of the food product by a 5% CH_3COOH soln. After the extn. centrifuge the mixt., ppt. the proteins, the tannic substances and the pigments with $CaCO_3$ + $(CH_3COO)_2Pb$, centrifuge again, ppt. the Pb with H_2S gas, remove it with CO_2 and titrate the filtrate with a 0.001 *N* soln. of 2,6-dichlorophenolindophenol until a pink color is obtained. The results obtained by the use of this new method are very close to those obtained by the method of Bukin. The new method, however, does not require any expensive reagents. W. R. Henn

A new method for the colorimetric determination of vitamin C. E. Schulek and I. Floderer. *Angew. Chem.* **52**, 615–16(1939).—The method is based on the quant. reduction of Fe^{+++} to Fe^{++} by ascorbic acid and photometric detn. of Fe^{++} by means of the α,α'-bipyridyl complex. Directions and reagent compns. are given. Exptl. results on synthetic ascorbic acid and exts. of lemons and oranges are presented. Four references. Karl Kammermeyer

Comparison of the antihemorrhagic activity of natural and synthetic vitamin K_1 with the proposed standard, 2-methyl-1,4-naphthoquinone. A. D. Emmett, R. A. Brown and Oliver Kamm. *J. Biol. Chem.* **132**, 467–8 (1940).—It is suggested that the use of 2-methyl-1,4-naphthoquinone be tentatively adopted as a standard of reference for the bioassay of the potency of vitamin K_1 preps. By defining the biol. activity of 1 γ of this quinone as 1 standard unit of vitamin K_1, it was found in a series of 6 expts. with 260 chicks, with the Thayer-Doisy method (*C. A.* **33**, 8246[3]), that it is equiv. to 1.98 of the authors' curative chick units; this makes their conversion factor 0.5. Natural and synthetic vitamin K_1 have substantially the same values and the av. potency (450) is very nearly 500 standard units per mg. This gives a somewhat higher value for natural vitamin K_1 than the 262 units reported recently by Almquist and Klose (*C. A.* **33**, 9382[1]). A. P. Lothrop

A colorimetric micromethod for the determination of sodium with manganous uranyl acetate. Ernst Leva. *J. Biol. Chem.* **132**, 487–99(1940).—In the micromethod described Na is ppt'd. by Mn uranyl acetate as the triple acetate. The ppt. is treated with KIO_4 and the soln. of permanganate thus obtained is measured by comparison with a $KMnO_4$ standard in a colorimeter or directly in an Evelyn photoelec. colorimeter. Phosphate in biol.

material does not interfere but K causes high results if the molar ratio of K:Na in the sample exceeds 1.5. Quantities of 0.008 to 0.01 mg. of Na have been detd. photoelectrically by the method with an accuracy of ±8%. A. P. Lothrop

The determination of vitamin A and carotene with the photoelectric colorimeter. C. J. Koehn and W. C. Sherman. *J. Biol. Chem.* **132**, 527–38(1940).—Although the photoelec. colorimeter affords a rapid and reliable means of detg. carotene and vitamin A, there are certain inherent limitations in its use and to obtain a high degree of accuracy with the instrument, a calibration curve should be used in which the values of 2-log *G* are plotted against the concn. over a series of dilns. of the material to be detd. since 2-log *G* is not a strictly linear function of the concn. of the chromogens. Calcns. are given for converting colorimeter readings into I. U. of vitamin A and γ of carotene, the factor being 2120 for converting $E^{1\%}_{1\ cm.}$ (328 mμ) into I. U. of vitamin A per g. and 1645 for β-carotene in $CHCl_3$ soln. ($L^{1\%}_{1\ cm.}$ 440 mμ). A. P. L.

The colorimetric assay of total, α- and β-17-ketosteroids in extracts of human urine. N. B. Talbot, Allan M. Butler and E. MacLachlan. *J. Biol. Chem.* **132**, 595–603(1940); cf. *C. A.* **33**, 9345⁹.—A method is described for the detn. of total, α- and β-ketosteroids in crude alc. solns. of the neutral fraction of urine exts. in which the light absorption due to nonketonic substances is subtracted in the colorimetric assay. Purification of the exts. with Girard's reagent T causes no significant loss but clearing exts. with decolorizing charcoal is unnecessary and may entail appreciable loss of hormone. The accuracy of the detns. depends upon establishing the optimal conditions for hydrolysis and extn. A. P. L.

A micromethod for the determination of carbon dioxide in blood and other fluids. Edward S. West, Bert E. Christensen and Robert E. Rinehart. *J. Biol. Chem.* **132**, 681–6(1940); cf. *C. A.* **34**, 2898.—A simple inexpensive app. is described in which the total CO_2 content of plasma and other fluids can be detd. in 15 min. The results agree within 1% with those obtained with the manometric method. The method is based on the principle of Pettenkopfer (Lunge, *Tech. Gas Analysis*, p. 221; *C. A.* **28**, 2646⁶) in which the CO_2 is drawn into an evacuated vessel contg. standard 0.05 *N* $Ba(OH)_2$ soln., the excess of which is titrated with 0.03 *N* HCl from a microburet. A. P. Lothrop

The determination of total base in biological material by electrodialysis. W. V. Consolazio and John H. Talbott. *J. Biol. Chem.* **132**, 753–67(1940). An improved unit is described for use in the detn. of total base in serum, blood cells, urine, tissues and other biol. media by electrodialysis. It is easy to manipulate and allows increased efficiency and greater accuracy and recovery of total base is complete. Approx. 0.2 ml. or 0.2 g. of material is adequate. The app. can also be used for the detn. of NH_3 in urine or in other biol. fluid advantageously when only small amts. of material are available. Cf. Keys, *C. A.* **30**, 5603⁶, and Joseph and Stadie, *C. A.* **32**, 9132¹. A. P. Lothrop

Determination of magnesium in biological materials. An oxidation method. John P. Nielsen. *Ind. Eng. Chem., Anal. Ed.* **11**, 649–51(1939); cf. *C. A.* **26**, 4353; **29**, 6265⁸, 8036⁸.—Mg pptd. with 8-hydroxyquinoline is detd. by oxidation with ammonium hexanitratocerate and titration of excess cerate with ferrous ammonium sulfate; *o*-phenanthroline ferrous sulfate is used as indicator. Analyses of canned tomato ash by this method agree with those by A. O. A. C. tentative method. J. McAfee

The determination of small quantities of iodine in biological materials. J. Trtílek. *Chem. Obzor* **14**, 196–8 (1939).—In a modified Leipert app. (*C. A.* **27**, 4266) without any rubber tubing, with a dephlegmator between the distg. flask and condenser, and without the useless 2nd condenser vessel, T. oxidized the org. substances with CrO_3 in the presence of H_2SO_4 and traces of $CeSO_4$, reduced the iodic acid with Na_2AsO_3 and volatilized the free I under low pressure into NaOH. After the soln. was concd., the I was oxidized with Br water and titrated by the Winkler method. The modified method eliminated all of the criticisms raised against the original app. Addns. of 1–5 γ of I to 10 cc. of blood were detd. with an accuracy of 10–20%. In 50-cc. urine samples, which could be concd., the accuracy of the I detns. was higher than 10%. Frank Maresh

The identification of synthetic malaria therapeutics in the urine. P. Dubost and M. Allinne. *Bull. sci. pharmacol.* **46**, 367–75(1939).—The substances investigated were: quinacrine (chlorodiethylaminopentylaminomethoxyacridine-2HCl), rhodopraequine, a mixt. of equal parts of rhodoquine(8-(diethylaminopropylamino)-6-methoxyquinoline) and praequine (8-(diethylaminoisoamylamino)-6-methoxyquinoline) as salts of an org. acid, and premaline, a mixt. of praequine, rhodoquine and quinacrine. Rhodoquine and praequine can be pptd. in the urine with Tanret's reagent (*C. A.* **7**, 2234). If protein is present previous extn. with Et_2O is necessary. For colorimetric detn. of the extd. base the reaction with HIO_3 is convenient (violet color), but it is not specific if quinacrine has been given during the preceding month or quinine during the last 4 days. In this case, the diazo reaction must be used. Quinacrine alone, in absence of protein, can be pptd. with Tanret's reagent. In the presence of protein or other medicaments the fluorescence of the dil. urine is detd. If the concn. is very weak, extn. with AmOH (method of Lataste and Farinaud, cf. *C. A.* **33**, 3863⁵) is used. For detn. the base is extd. with Et_2ONH_4OH by Dantec's method (*C. A.* **30**, 3587⁹). The detn. of fluorescence is not impeded by quinine, as is the case if Dantec's soln. of Br and $SnCl_2$ is used. Premaline is identified by its quinacrine component. The elimination is about 1/10 of the ingestion daily and extends over a long time. The concn. seldom exceeds 2–3 mg. per l. for praequine and rhodoquine and 30–50 mg. for quinacrine. A. E. Meyer

The microdetermination of cholesterol in serum. Herbert K. Alber and J. T. Bryant. *J. Franklin Inst.* **229**, 118–25(1940).—The method is essentially a modification of that of Schoenheimer and Sperry (*C. A.* **28**, 6752⁹) and incorporates the modifications suggested by Fitz (*C. A.* **29**, 4787⁵). The chief changes are the use of a cool acetone-alc. extn. mixt., and of slightly larger amts. of serum than were originally proposed. The digitonin precipitant has been changed to 0.2 g. digitonin in 100 ml. 50 volume % EtOH, and the AcOH-acetic anhydride.H_2SO_4 ratio has been increased. The colorimetric detn. of the cholesterol using an ordinary Duboscq colorimeter has been accurately tested against standard Naphthol Green B solns., the efficiency and stability of which have been detd. against standard cholesterol digitonide solns. in glacial AcOH. The accuracy and precision of the modified method have been found to be equiv. to those of the more complicated method usually employed. Edward B. Sanigar

Method of assaying pituitary water-retention principle. Eldon M. Boyd and Edward G. Mack. *Endocrinology* **26**, 153–9(1940); cf. *C. A.* **34**, 527⁵.—A method is described for the assay of pituitary water-retention principle based on changes in the body water of leopard frogs (*Rana pipiens*) immersed in water at 4° and read in terms of a proposed frog unit. Felix Saunders

Enzymic degradation of polyamines. V. The occurrence of diamine oxidase in man, mammal and bird, with an appendix on the occurrence of cholinesterase in birds. E. A. Zeller, Hans Birkhäuser, Hans Mislin and Marianne Wenk. *Helv. Chim. Acta* **22**, 1381–95(1939)(in German); cf. *C. A.* **32**, 7059⁵; **33**, 1765⁴, 7832⁹.—*Detn. of diamine oxidase* (I).—The fresh organs are ground with sea sand, mixed with 3 times the amt. of 2.5% NaCl and dialyzed at 0°, first against distd. water and a few hrs. later against Sørensen phosphate buffer (pH 7.2). After 24 hrs. the mixt. is centrifuged and the supernatant liquid dialyzed, usually for 48 hrs. To 2.5 cc. of the dialyzed enzyme soln. is added 0.1–0.3 cc. 0.1 *M* cadaverine di-HCl dissolved in the above buffer, the vol. is dild. to 3.0 cc. with pure buffer soln., and 1–2 drops primary octyl alc. and 0.25 cc. toluene are added. With small organs the vols. are decreased (up to 1.5 cc.). In organs with very small amts.

of I the NH_3 liberated in 4–20 hrs. is detd. by the Parnas method (*C. A.* **29**, 1123[4]). In all other cases the O consumption in 1–2 hrs. is measured in the open Warburg manometer. Under these conditions the unit of I is the initial velocity of oxidation of 10^{-6} mol. cadaverine per hr. on complete satn. of the enzyme by the substrate. This corresponds to the formation of 17 γ NH_3/hr. and to the consumption of 11.2 cu. mm. O_2/hr. If histamine is used as the substrate, the "histamine unit" represents a larger amt. of I than the "cadaverine unit"; the factor is 1.3 for an optimal histamine concn. Errors due to the consumption of the 2nd O atom in the diamine-I reaction are negligible. The estn. of the blank values presents difficulties not yet solved. The av. I unit varied from 0 for the brain of a newborn infant and for the kidneys of a duck 4 weeks old and 0–2 for the liver of an adult pig to 20 for the renal cortex of an adult pig, estd. per g. fresh organ. The kidneys of most of the mammals studied, with the exception of the rodents, contained considerable I. The cortex was much richer in I than the medulla, except in man where both had about the same activity and in the human newborn where the medulla had a much higher I content. The concn. of I in the kidneys was smaller in birds than in mammals; the change in magnitude from one species of birds to another revealed no apparent regularity. I in the liver of mammals varied between 0 and 2 I units. With the exception of rodents, the values were regularly smaller than those of the corresponding kidneys, while in birds the relations were reversed. I was found in the intestinal mucosa of all the warm-blooded animals with the possible exception of the starling. The human adrenal and pancreas contained considerable I. For the prepn. of I the renal cortex of the pig is the richest source. *Detn. of cholinesterase* (II).—The fresh organs are ground with sand and 6 times the amt. of Ringer bicarbonate soln., and centrifuged. To 0.5 cc. supernatant fluid is added 2.5–4 mg. acetylcholine, the vol. is dild. to 2 cc. and II is estd. at 38° by the Ammon method (*C. A.* **28**, 1724[9]). Physostigmine was used in the control detns. The results, expressed in cu. mm. CO_2 liberated in 30 min., varied from 375 for the cerebral hemisphere of a kestrel 30 days old to 12.5 for the cortex of the hemisphere of a man 40 years old. Ruth Berggren

Handbuch der biologischen Arbeitsmethoden. Edited by **E. Abderhalden.** Abt. II. Physikalische Methoden. Tl. 3. Heft 7. Lfg. 482. Pp. 3717–4328. M. 40. Inhaltsübersicht. 127 pp. Berlin: Urban & Schwarzenberg. Cf. *C. A.* **33**, 4281[2].

C—MICROBIOLOGY

LAWRENCE H. JAMES

Morphological, histological and chemical researches on the melanosis of the appendix. Francesco Bordonaro. *Pathologica* **31**, 497–513(1939).—The genesis of the melanin and the chem. nature of the natural chromogenic substances that produce melanins are discussed. The identification of melanoblastic elements in the appendix is very difficult because of the great no. of polynuclear leucocytes (giving melanin reactions). G. A. Bravo

Action of microörganisms on fats. I. The significance of color changes in dyes used for the detection of microbial action on fat. C. H. Castell and L. R. Bryant. *Iowa State Coll. J. Sci.* **13**, 313–27(1939).—Color changes in Nile Blue sulfate, or methylene blue, or *p*-aminodimethylaniline monohydrochloride are not due to simple reactions of a single type and cannot be used as specific indications of any one type (e. g., hydrolysis of fat). Extn. of dyes from aq. soln. and reduction are probable causes of color changes. F. E. Brown

Thiamine effects in bacterial metabolism. M. Silverman and C. H. Werkman. *Iowa State Coll. J. Sci.* **13**, 365–8(1939).—Some bacteria, e. g., *Propionibacterium peterssonii*, cannot oxidize pyruvate under anaerobic conditions in the absence of thiamine (vitamin B_1), but the addn. of 2 γ of thiamine to 2 cc. of their cell suspension produces fairly rapid oxidation. Other strains, e. g., *Aerobacter indologenes*, either do not require thiamine to oxidize pyruvate or else synthesize their own thiamine as required. F. E. Brown

Leucocidal toxin extracted from typhoid bacilli. Emery Westervelt Dennis and Haratune Senekjian. *Am. J. Hyg.* **30B**, 103–11(1939).—Typhoid leucocidin (I) is an integral part of the typhoid bacillus from which it can be extd. with *N*/4 CCl_3COOH. Purification of the ext. results in increased potency of the toxic somatic antigen complex but in a loss of leucocidal activity. I is not in an antigenic state in CCl_3COOH exts. One prepn. yielded 940 mg. of purified I from 8.55 g. of dry bacilli. The N and P each averaged 4.7%. After hydrolysis there was an av. of 19.9% of apparent carbohydrate calcd. as glucose. I must be heated to 100° for 2 hrs. for complete inactivation. Leucocidin can be demonstrated in similar exts. of *Salmonella typhimurium*, *S. schottmülleri*, *S. suipestifer* (voldagsen strain), *S. enteritidis*, *S. gallinarum* and *S. paratyphi*. Rachel Brown

The influence of normal blood and certain of its constituents on the growth and viability of the tubercle bacillus. R. Davies. *Tubercle* **20**, Suppl. 49 pp.(May, 1939).—The growth of a virulent human-type tubercle bacillus on an egg yolk-saline medium is completely inhibited in the presence of concns. of blood or corpuscles (hemoglobin, 10%) of 5 volumes % or over, and almost completely inhibited in the presence of 1 vol. % of blood. Growth is completely inhibited by 0.1% of ferrous NH_4 sulfate and is partially inhibited by 0.035% and 0.007% of this substance. Plasma (5 vol. %) has no significant effect on growth. Colloidal $Fe(OH)_3$ in concns. up to 0.028% has no significant effect on growth. A strain of tubercle bacilli remains viable for a longer time on a Long-agar medium contg. 5 or 10% of blood or 10% of corpuscles than it does on plain Long-agar medium or on this medium plus 1%, 5% or 10% plasma. Concns. of 1%, 5% and 16.7% of rabbit blood inhibit the growth of H 37 tubercle bacilli on Long's medium by 84%, 88% and 100%, resp. The red corpuscles also inhibit the growth but do not account for the whole of the inhibition observed with blood, the corresponding degrees of inhibition being 70%, 50% and 81%. Plasma may have a beneficial effect on the growth of the tubercle bacillus, which effect is masked in the expts. by the small quantity of red-corpuscle content which the plasma prepn. contains. The presence of blood or corpuscles in the medium permits the development of colonies of tubercle bacilli in the depths of the medium. The substance present in the red blood corpuscles which inhibits the growth is shown to be contained in the protein fraction of these corpuscles. The inhibitory action of red corpuscles evidenced with Long's medium is completely abolished by heating for ½ hr. at 100° or 20 min. at 120°. The heated red blood corpuscles have a slight beneficial effect on the growth. During the incubation period any hemoglobin in the medium is partly destroyed and partly converted into parahematin and hemochromogen. Suspensions of a virulent human strain of tubercle bacillus in distd. water, Long's medium + 1.5% Na citrate, and 0.9% saline + 1.5% Na citrate fail to produce tuberculosis when injected into guinea pigs after 1- and 4-day incubation at 37°, resp. Tubercle bacilli incubated with citrated whole human blood show no diminution in their ability to produce tuberculosis in guinea pigs even after 14-day incubation. It is suggested that the rapid death rate in the case of the first-mentioned suspensions is due to a lack of available sources of energy in the suspension medium. H. J. Corper

The pathogenicity of BCG after prolonged cultivation on glycerinated egg medium. William H. Feldman. *Tubercle* **20**, 253–62(1939).—A culture of BCG obtained from Calmette in 1930 was subcultured for 59 generations during a 6-yr. period on glycerinated egg yolk slants. A series of 12 guinea pigs and 18 rabbits were inoculated with 2 mg. subcutaneously, intraperitoneally or intravenously.

The expt. was continued for 15 months when the surviving animals were killed. In no instance was there observed a progressive, malignant, tuberculous disease. The data indicate that cultivation of a strain of BCG for a period of approximately 6 yrs. on glycerinated egg medium did not increase its virulence for guinea pigs or for rabbits. H. J. Corper

Uses and limitations of the coliform group in sanitary control of food production. Albert C. Hunter. *Food Research* **4**, 531–8(1939).—The term "coliform" is used to designate lactose-fermenting, aerobic and nonsporulating bacteria. Coliform bacteria, which are indole-pos., methyl red-pos., Voges-Proskauer-neg. and do not utilize citric acid as a source of C, are useful as a measure of excretal contamination. An editorial. C. R. F.

Two strains of Clostridium botulinum type E: incitants of human botulism. Elizabeth L. Hazen. *Health News, N. Y. State Dept. Health* **15**, No. 39, 162(1938); *U. S. Pub. Health Eng. Abstracts* **19**, Mi, 15(Apr. 29, 1939).—Type E *Clostridium botulinum* was isolated from Nova Scotia smoked salmon and also from German-canned sprats. Serological tests showed that these cultures were identical to type E strains originally isolated from fish in Russia. These 2 organisms were the cause of fatal cases of botulism in N. Y. Type E strains, largely overlooked in the past, are apparently widely distributed. C. R. Fellers

Glucides in the filtrates of tubercle bacillus cultures. K. O. Streng. *Compt. rend. soc. biol.* **132**, 202–5(1939).—The filtrates contain small amts. of simple glucides which do not reduce Fehling soln. but which are fermented to acids by dysentery bacilli. The compds. are probably polyalcohols. L. E. Gilson

Xanthoproteic reaction and presence of tuberculin in cultures of avian tubercle bacillus in Sauton medium. F. van Deinse. *Compt. rend. soc. biol.* **132**, 206–7(1939); cf. *C. A.* **33**, 6898[8].—With avian strains the culture fluid gave a xanthoproteic reaction 9–38 days before the appearance of tuberculin, with bovine strains the reaction was not pos. until 3–24 days after the appearance of tuberculin, and with human strains the xanthoproteic and tuberculin tests became pos. at the same time. L. E. Gilson

Ultrafiltration of the toxin of Bacillus perfringens type C. Serge Levenson and Pierre Grabar. *Compt. rend. soc. biol.* **132**, 210–13(1939); cf. *C. A.* **33**, 6378[8].—The hemolysin passes through a membrane with a pore diam. of 29 mμ but is all retained by one with a pore diam. of 23.5 mμ. A nonhemolytic purely toxic factor is present which passes to some extent through a membrane with a pore diam. of 6 mμ. L. E. Gilson

Fermentation of sugars by Ramibacterium ramosoides (Rüneberg) P. 1938. A. R. Prévot and R. Veillon. *Compt. rend. soc. biol.* **132**, 239–41(1939); cf. *C. A.* **32**, 7952[9].—In broth with added sugar the organism ferments glucose, maltose and lactose forming 1 part AcOH and 2 parts $EtCO_2H$, but no EtOH or lactic or succinic acid. Indole and NH_3 are also formed. L. E. Gilson

Physiological and systematic study of some Chlamydobacteriales. María S. Cataldi. *Rev. inst. bacteriol. dept. nacl. hig.* (Buenos Aires) **9**, 1–97(1939).—*Sphaerotilus dichotoma* and various species of *Leptothrix* (so-called iron bacteria) were studied. They are not autotrophic as some have claimed and cannot develop in completely mineral media. The presence or absence of Fe^{+++} or Mn^{++} salts does not seem to influence the quantity or quality of development. Expts. with various culture media are described. L. E. Gilson

Physicochemical aspects of bacterial growth. IV. Conditions determining stationary populations and growth rates of Bact. lactis aerogenes in synthetic media. R. M. Lodge and C. N. Hinshelwood. *J. Chem. Soc.* **1939**, 1683–92; cf. *C. A.* **33**, 3418[9].—The abundance of growth of *Bact. lactis aerogenes*, as measured by the max. stationary concn., does not necessarily correspond with the actual rate of growth in artificial lactose-tartrate and glucose-phosphate media at 40°. The influence of pH on the max. population depends on the nature and concn. of the medium: in a concd. glucose-phosphate soln. the max. population is independent of pH over an appreciable range. In a lactose-tartrate medium, contg. a small amt. of $NH_4H_2PO_4$, the max. population which the medium can support at first increases in proportion to, and then becomes independent of, the concn. of the main constituents. The onset of the stationary state appears to be due to exhaustion of the substances required for growth, accumulation of toxic products and changes of pH. At adverse pH values the stationary population is greatly diminished, but there is no corresponding change in the rate of growth. To account for this it is suggested that different stages of bacterial growth have different locations. V. **Influence of magnesium on the lag phase in the growth of Bact. lactis aerogenes in synthetic media containing phosphate.** *Ibid.* 1692–7.—A certain min. concn. of Mg ions is essential for the growth of *Bact. lactis aerogenes* in artificial media contg. glucose, $(NH_4)_2SO_4$ and KH_2PO_4: below this concn. there is no growth, but above it growth is normal and both rate and max. population are approximately independent of the amt. of Mg present. There is a limiting interval which may elapse between the introduction of the organism to a Mg-free medium and the subsequent addn. of Mg for growth to continue. In solns. contg. little or no Mg there is a lag phase in which it is believed that the bacteria are synthesizing a necessary intermediate growth substance and also dying off at a definite rate. If they are all dead before the end of the lag period, the length of which decreases with increasing Mg concn., no growth will be observed on addn. of Mg. The relation between the Mg concn. and the shortening of the lag phase can be deduced from a knowledge of the death rate, the mean generation time and the min. amt. of Mg necessary for growth. S. Glasstone

Physiological difference between 1,3- and 2,3-butylene glycol. Kinitiro Sakaguti and Osamu Kambayasi. *J. Agr. Chem. Soc. Japan* **15**, 1019–22; *Bull. Agr. Chem. Soc. Japan* **15**, 143(in English)(1939).—2,3-Butylene glycol, as well as glycerol, was utilized as a C source by various kinds of microörganisms, while 1,3-butylene glycol was assimilated only by *Oidium lactis* and *Bacillus mesentericus*. Ethylene glycol was utilized by *Bacillus mesentericus, Aspergillus oryzae* A, *Penicillium glaucum, Rhizopus chinensis, Monilia fructigena* and *O. lactis*. Y. Kihara

Production of 2,3-butylene glycol by fermentation. I. Kinitiro Sakaguti, Kisetu Ôhara and Sumihiko Kobayasi. *J. Agr. Chem. Soc. Japan* **15**, 1075–84; *Bull. Agr. Chem. Soc. Japan* **15**, 148(in English)(1939).—Ten strains of bacteria producing 2,3-butylene glycol in a yield of 30–40% from glucose were isolated from soil and vegetables. Seven of them belonged to *Aerobacter aerogenes* and the other three to *A. cloacae*. They produced not only glycol but also remarkable amts. of EtOH. The production of glycol was optimum at 37–8° and pH 6–7. The most preferable concn. of glucose was 8%. Soybean cake, fish meal and rice bran with the addn. of a small amt. of $(NH_4)_2SO_4$ were most suitable N sources. The production of 2,3-butylene glycol was detected in the culture soln. by the Voges-Proskauer test after treatment of the mediums with dil. H_2SO_4 and $KMnO_4$ soln. The existence of 0.2 g. of furfural in 1 l. of the culture soln. did not retard the fermentation. Y. Kihara

A note on the characters of a coccus isolated from South Australian stout. Lance S. Walters. *J. Inst. Brewing* **46**, 11–14(1940).—Morphological, cultural and physiol. characters are described. It is regarded as a variant strain of *Streptococcus tetragenus* (Claussen) (Shimwell and Kirkpatrick) and possesses the distinguishing character of fermenting xylose and arabinose. Quick Landis

Biochemical hydrogenation of steroids by putrefactive bacilli. Luigi Mamoli, Richard Koch and Hermine Teschen. *Z. physiol. Chem.* **261**, 287–96(1939); cf. *C. A.* **33**, 2157[1].—*Bacillus putrificus* (Bienstock), anaerobically cultured in yeast water at pH 6.8, with powdered androstenedione (I) gives 70–80% of etiocholanedione, testosterone (II) gives 70–80% of etiocholan-17-ol-3-one (III), and progesterone (IV) gives 80–90% of pregnanedione.

If the medium is a sterile yeast suspension, keto groups are reduced in addn. to the double bonds. Thus I gave III and *epi*-3,17-etiocholanediol (V), androstenedione gave isoandrosterone and isoandrostenediol, II gave III and V. Dehydroandrosterone gave androstenediol, IV gave the same product as before. Cholesterone is not acted upon. Stereo specificity is marked in these changes. Relationships between structural groups and the configuration of products are indicated. Milton Levy

Effect of sulfanilamide upon the Shwartzman phenomenon and upon the growth of meningococci in vitro. S. Stanley Schneierson. *J. Infectious Diseases* **65**, 97–102(1939).—Sulfanilamide and prontosil have no effect upon the Shwartzman active principles of meningococcus filtrates or upon meningococci killed by drying but do inhibit the Shwartzman reaction with washed living organisms provided the amt. injected does not exceed 100 million organisms. The drugs inhibit the reaction with washed living organisms because they are bacteriostatic and inhibit the formation of toxin. When larger amts. of organisms are given the liberated preformed toxin may produce a reaction. Julian H. Lewis

Mucoid dissociation in the colon-typhoid-salmonella group. H. R. Morgan and T. D. Beckwith. *J. Infectious Diseases* **65**, 113–24(1939); cf. *C. A.* **33**, 5439[6].—A relatively low temp. of incubation (10–20°) produces the mucoid dissociant among members of colon-typhoid-salmonella organisms. Carbohydrate is essential to the formation of the capsular substance. The polysaccharide of the capsule is active immunologically and appears to have a stable antigenic pattern since its formation and serological characteristics are independent of the configuration of the carbohydrate from which it is formed. Julian H. Lewis

An ectoenzyme of Clostridium welchii which decomposes blood group specific substance A. Fritz Schiff. *J. Infectious Diseases* **65**, 127–33(1939).—From cultures of *Cl. welchii*, a germ-free, group-specific enzyme was prepd. by filtration and pptn. with acetone. The production of the enzyme in cultures is suppressed in the presence of such carbohydrates as are fermented by *Cl. welchii*. The enzyme will specifically destroy the blood group specific substance *A*. It is destroyed at pH 6 and at values below this. It is inactivated by oxidation (standing at room temp.) and can be reactivated by reduction (with ascorbic acid under anaerobic conditions). The enzyme is not related to any hemotoxin. J. H. L.

The nutritive requirements of Salmonella. II. The formation of indole and tryptophan by the typhoid bacillus. Wm. Burrows. *J. Infectious Diseases* **65**, 134–41(1939).—Previously reported evidence (*C. A.* **33**, 7840[2]) for the synthesis of the "essential" amino acid tryptophan by the typhoid bacillus and the formation of indole by this organism is confirmed and extended through the presentation of quant. data. Julian H. Lewis

Studies on lactobacilli. I. Fermentation reactions of strains isolated from human mouths. R. W. Harrison. *J. Infectious Diseases* **65**, 142–6(1939).—The fermentation reactions of oral lactobacilli, isolated from patients with various degrees of dental caries activity, were studied in milk and 10 carbohydrates. There was little correspondence between morphology of the 111 strains tested and their fermentation reactions, except for the concn. of 2 of the 3 morphological groups in the group with more vigorous fermentative reaction. Julian H. Lewis

Nicotinamide and related compounds as essential growth substances for dysentery bacilli. Albert Dorfman, Stewart A. Koser, Harold R. Reames, Karl F. Swingle and Felix Saunders. *J. Infectious Diseases* **65**, 163–82 (1939).—The growth-promoting activity of spleen exts. for dysentery bacilli can be attributed to the presence of either nicotinic acid, which was isolated from pig spleen, or nicotinamide, whose presence was strongly indicated, or of both. Other known growth factors, with the exception of coenzymes I and II, were not capable of replacing either partially or completely nicotinic acid or its amide. Many of 33 representative cultures of the *Shigella* group were unable to grow in a synthetic medium but developed readily upon the addn. of small amts. of either the coenzymes, nicotinic acid or its amide. Those cultures which required nicotinic acid or its amide were able to develop through successive transfers when these compds. were supplied in the synthetic medium. No restraining action of nicotinic acid was observed in amts. up to 1000 γ/cc. medium, but with 3000 or more γ/cc. progressive inhibition was found. Within 24 hrs. after inoculation nicotinamide was 10 times as potent as nicotinic acid; less difference was noted in the growth-promoting effect with longer periods after inoculation. This may probably indicate a necessary conversion of the acid to amide before utilization. The dysentery bacillus growing in a synthetic medium contg. nicotinic acid synthesized a growth-promoting substance for several *Hemophilus* species which was probably coenzyme I or II or some related substance. A growth-promoting substance for staphylococcus was synthesized which may be thiamine or its component parts and possibly biotin. Riboflavin was also synthesized. A study of 24 compds. structurally related to nicotinic acid showed that any change in ring substitution resulted in loss of activity. Esterification resulted in decreasing activity with increasing length of the alkyl chain. Substitution on the amide N resulted in a marked decrease of activity. Nicotinuric acid was comparable in activity to nicotinic acid. A close correspondence was found between the activity of these compds. as essential growth factors for the dysentery bacillus, the reported activity for *Staphylococcus aureus* and the curative effect on canine blacktongue and human pellagra. J. H. Lewis

The fate of the capsule (P) substance of the anthrax bacillus in the organism. G. Ivánovics. *Z. Immunitäts.* **96**, 408–12(1939).—Evidence is given that the *P* substance from anthrax bacilli, a polypeptide of glutamic acid, is excreted entirely through the kidneys and that none of it is stored or destroyed in the body. J. H. Lewis

Influence of metals on diphtheria toxin formation. M. O. Hettche and M. Becker. *Z. Immunitäts.* **96**, 440–4 (1939).—In mediums contg. Fe in concns. ranging from 0.005 to 0.05%, diphtheria toxin production varies from 0 to normal amts. Bacterial growth under these conditions is not influenced. Fe as cation of complex Fe salts or Fe compds. is active while the Fe in the anion of these compds. is without action. The other metals of the Fe group, Ni and Co, are inactive. Cu does not decrease toxin formation but is a disinfectant. The protective action of Fe in guinea pigs infected with diphtheria does not depend on inhibition of bacterial ferments but on its effect on the reticulo-endothelial cells. J. H. Lewis

The production of an ectotoxin by the Schmitz dysentery bacillus. H. Buchwald. *Z. Immunitäts.* **96**, 445–54 (1939).—The production of an ectotoxin and the behavior of the toxin gives the Schmitz bacillus a special place between the true dysentery and the pseudodysentery organisms. Julian H. Lewis

Pituitary extracts and the virus of foot-and-mouth disease. The effect on the virus of certain chemical methods employed in their preparation. I. A. Galloway. *J. Hyg.* **39**, 597–614(1939).—Acetone desiccation of pituitary will not kill foot-and-mouth virus. Prepns. of crude prolactin by alk. extn. in the cold followed by pptn. and repptn. at pH 5.5 and sepn. of the crude thyrotropic fraction will destroy any virus. Prepn. of crude whole ext. of anterior lobe (B fraction) will destroy the virus. Alc. (60%) at 18°–20° did not render the material noninfectious. If any doubt exists as to the possible contamination of a hormone prepn. with the virus of foot-and-mouth disease, it can be made safe by suspending in a fluid with a pH of 4.5–5.0 at room temp. and bringing it back to neutrality. 12 references. John T. Myers

The value of the sodium *d*-tartrate fermentation test in the differentiation of the Salmonella organisms. S. W. Challinor and A. J. Rhodes. *J. Hyg.* **39**, 651–7(1939).—*B. paratyphi B* fails to ferment while *Salmonella aertrycke* and food-poisoning organisms do ferment Na *d*-tartrate. John T. Myers

The control of air-borne bacteria and fungus spores by means of aerosols. R. J. V. Pulvertaft and J. W.

Walker. *J. Hyg.* **39**, 696–704(1939); cf. *C. A.* **33**, 6525⁴.—NaClO may be used as the active ingredient in a bactericidal aerosol. Although less efficient than resorcinol prepns., it is cheaper and a good deodorant.
John T. Myers

The characters and systematic position of Morgan's bacillus. A. Sevin and R. Buttiaux. *J. Path. Bact.* **49**, 457–66(1939).—Morgan's bacillus no. 1 possesses distinct biochem. characters. It fails to ferment mannitol and lactose but ferments glucose, fructose and usually galactose with very slight gas production. It shows a community of antigens most marked in cultures on soft agar, and is antigenically related to *Proteus vulgaris*. 22 references.
John T. Myers

The effect of blood digest and hem on the growth of Corynebacterium diphtheriae. V. Glass. *J. Path. Bact.* **49**, 548–61(1939); cf. *C. A.* **33**, 6383¹.—Either peptic blood digest or hem will inhibit the growth of *C. diphtheriae*, especially under aerobic conditions. Some strains are more sensitive than others. This effect by blood digest is not changed by storage in the refrigerator but is reduced by boiling; that of hem gradually decreases on storage and the deterioration is accelerated by rise in temp. This inhibition is not accompanied by a diminution of the peroxidase activity. The amt. of hem required as "X" factor varies with different strains of *Hemophilus influenzae* and is of the same order as that required to inhibit *C. diphtheriae*. Under certain conditions inhibition is caused by hematoporphyrin. Ferri et ammonii citras (B. P.) (0.5%) caused no inhibition. The above inhibition may be partially neutralized by appropriate concns. of Na hyposulfite. HCN inhibits the growth of *C. diphtheriae*, especially under aerobic conditions, but is somewhat antagonistic to hem.
John T. Myers

The toxin of B. parapertussis and the relation of this organism to Hemophilus pertussis and Alcaligenes bronchiseptica. I. E. Bruckner and D. G. Evans. *J. Path. Bact.* **49**, 563–70(1939).—The toxin of *B. parapertussis* is very similar to those of *H. pertussis* and *A. bronchiseptica*, but is not so potent. It is extremely labile and no evidence that it is antigenic was obtained.
John T. Myers

The effect of iodine vapors on several viruses. M. Kaiser. *Arch. ges. Virusforsch.* **1**, 237–46(1939).—Expts. in rabbits show that vaccinia virus is inactivated by a min. or 30-sec. contact with I vapors. The I probably undergoes chem. combination with the virus, since it cannot be washed away nor does it irritate corneal epithelium in this form. A virus which has been subjected to I vapors for 5 min. is not altered by subsequent treatment with a 0.1 *N* soln. of thiosulfate. If the thiosulfate is applied after only 30-sec. contact with I, however, the virus shows some stabilization, i. e., it is not completely killed although no reactions occur upon injection in rabbit testicles. Myxoma virus behaves like vaccinia virus and is completely inactivated by 5-min. contact with I vapors. The dried, fixed virus of Lyssa (rabies) is considerably detoxified after 15-min. contact with I vapors, but the majority of guinea pigs succumb 8 days after the injection of treated virus.
J. Pinchack

The behavior of bacteriophages injected intracisternally. K. Burckhardt. *Arch. ges. Virusforsch.* **1**, 247–51 (1939).—*Escherichia coli* phages can be detected in the serum a short time after intraspinal injection of concd. solns. The smallest concn. of which it is still possible to detect traces is 10^{-6}. Such traces can be detected only if the total serum of the bled animal is used in the manner described.
J. Pinchack

The mode of action of formaldehyde upon phage protein. Hideo Moriyama and Shunkichi Ohashi. *Arch. ges. Virusforsch.* **1**, 252–66(1939)(in English).—HCHO inactivation of *Escherichia coli* phage is a mononuclear reaction directly proportional to the concn. of HCHO, the min. active one being 0.01%. Only about 5% of the HCHO is permanently combined, the rest being in a state capable of reducing I. Under certain conditions, the inactivated phage may be reactivated by diln. with water or by dialysis. Inactivation of phage by HCHO is enhanced by the OH ion.
J. Pinchack

The inactivation of phage protein by neutralization of its acidified solution. Hideo Moriyama and Shunkichi Ohashi. *Arch. ges. Virusforsch.* **1**, 267–72(1939)(in English); cf. *C. A.* **33**, 8678⁸.—*Escherichia coli* phage protein can be severely damaged if its acidified soln. is neutralized in a water medium contg. no salt. Inorg. salts ($CaCl_2$, $MgCl_2$, $BaCl_2$) prevent such inactivation in as low a concn. as *N*/160. It may be proper in some cases to use Ringer's or a dil. $CaCl_2$ soln. instead of water in isolating virus proteins.
J. Pinchack

The water content of the particle of vaccinia virus protein. Hideo Moriyama. *Arch. ges. Virusforsch.* **1**, 273–82(1939)(in English); cf. *C. A.* **33**, 4288⁴,⁵, 8678⁸.—An approx. water content of 90% was estd. in vaccinia virus and *Escherichia coli* phage protein by means of centrifugation, by measuring the sugar-insol. space of the particle and from the filtrability of the particle.
J. P.

The effect of pH on the bactericidal power of urine containing sulfanilamide. J. R. Sickler. *Proc. Staff Meetings Mayo Clinic* **14**, 715–19(1939).—The bactericidal activity of normal urine contg. sulfanilamide toward *Escherichia coli*, *Staphylococcus aureus*, *Aerobacter aerogenes*, *Bacillus proteus*, *Salmonella* and *Pseudomonas aeruginosa* was found to increase when the H-ion concn. was changed from pH 6.2 to 7.7. A great variation was found in the level at which sulfanilamide acts bactericidally on different strains of the same group of organisms commonly found in urinary tract infections.
J. Pinchack

The impermeability of the viable obstructed bowel of dogs to Clostridium botulinum toxin. Carroll J. Bellis and Winford P. Larson. *Surgery* **6**, 901–8(1939).
J. Pinchack

Action of mercury salts on the formation of vitamin B_2 in Aspergillus niger. G. S. Kitaviu. *Biokhimiya* **4**, 283–94(1939).—The addn. of 10–20 mg. % of $HgCl_2$ to a glucose or sucrose soln. brings about the production of gluconic acid by *A. niger*, instead of citric and oxalic acid normally formed.
H. Priestley

Can sucrose be fermented directly, or is preliminary hydrolysis essential? G. P. Toropova. *Biokhimiya* **4**, 336–41(1939).—Willstatter's view that disaccharides may be fermented by a special zymase, without previous hydrolysis, could not be substantiated in the case of sucrose. All enzymic prepns. capable of fermenting sucrose were always found to contain invertase. Cf. W., *C. A.* **16**, 2154, 2528, **20**, 770, 1632.
H. Priestley

Ergosterol content of yeast during autolysis. A. V. Trufanov and V. A. Kirsanova. *Biokhimiya* **4**, 377–80 (1939).—The ergosterol content of yeast, as measured by the colorimetric method of Heiduschka and Lindner (*C. A.* **23**, 2737), increases during autolysis. The increase is ascribed to the liberation of free ergosterol, part of which is said to be present in the yeast in a combined form.
H. Priestley

Germicidal properties of the oxides of nitrogen. H. G. Williams and T. A. Hartgraves. *J. Lab. Clin. Med.* **25**, 257–63(1939).—A mixt. of gases produced by passing compressed air through an elec. arc is shown by controlled bacteriol. expts. to be an effective bacteriostatic and bactericidal agent and should find usefulness in the treatment of infected wounds and chronic draining sinuses. The bactericidal power may be due to the formation and deposition of min. amts. of HNO_3 and other unknown agents. When correctly used the gas does no harm to patient or tissues. It is also fungistatic and fungicidal. The vegetative forms of bacteria and fungi are the least resistant to the gas; the spore forms are very resistant.
Howard W. Robinson

A simple method for determining bacterial reduction of nitrates. Wm. A. Randall and Robert J. Reedy. *J. Lab. Clin. Med.* **25**, 315–16(1939).—A soln. of KNO_3 is added to a suspension of living bacterial cells, and after 15 min. to one hr. later the mixt. is tested for the presence of nitrites. This procedure was tested with 24 different species of bacteria and gave complete agreement

with the routine method which consists in inoculating broth containing KNO_3 with the test culture and testing for the presence of nitrites after incubation. Organisms which reduce the nitrate and utilize the nitrite will very likely give a pos. test with the simple method and a neg. test with the routine method. Howard W. Robinson

Bacterial reduction of trimethylamine oxide to trimethylamine. H. L. A. Tarr. *J. Fisheries Research Board Can.* **4**, 367–77(1939).—Only 3 of 30 microörganisms isolated at random from 7 samples of fish muscle in various stages of decompn. formed trimethylamine (I) from trimethylamine oxide (II). The reduction of II by the bacteria capable of effecting this reaction is due to the presence in their cells of an enzyme capable of activating the mol. and thus rendering it susceptible to reduction by any of a large number of dehydrogenase systems. T. therefore questions the use of the test for I to det. spoilage in fish. J. J. Willaman

THOMAS G. PHILLIPS

Accumulation of carbohydrates in leaves previously held in the dark. Paul P. Stanescu. *Compt. rend.* **209**, 803–5(1939); cf. *C. A.* **21**, 2292.—The daily rhythmic accumulation of carbohydrates in the leaves of *Prunus armeniaca* L. is faithfully reproduced by leaves maintained in the dark for different intervals prior to the expt. Leaves in which the photosynthesis was allowed to begin after 1 p. m. no longer presented the curves characteristic of the forenoon synthesis. Rachel Brown

The behavior of Phoma betae Frank. toward boron. O. Verona and I. De Marchi. *Ann. facoltà agrar. univ. Pisa* [N. S. 3rd] **2**, 645–54(1939).—B (as boric acid or Na borate) stimulates growth of *P. betae* at the concn. 0.01–0.02%; at a greater concn. it inhibits the development of the fungus. The cultures are not damaged by strongly alk. agents. G. A. Bravo

Notes on the Cordeauxia edulis or gehèb. P. Brilli and S. Mulas. *Agr. coloniale* (Italy) **33**, 565-70(1939).—*C. edulis* Hemsl. of the Italian Somaliland is a shrub that grows in sandy soils low in Ca and rich in Si and Fe. The rind and the almond of the fruit (edible) contain, resp., H_2O 10.71, 7.82; oil (of acid no. 1.93) 0.30, 12.44; ash 1.43, 3.01 (P_2O_5 in the ash 0.63%); protein 4.75, 11.81; cellulose 13.70, 3.36; N-free ext. 69.38, 61.56; reducing sugars (of the total fruit) 5.32, sucrose 11.61%. The leaves contain a red coloring matter, turning purple with alkali and are used for the prepn. of a tea substitute. G. A. Bravo

The culture of Hevea in Indochina. A. Thomas. *Rev. gén. caoutchouc* **16**, 248–56, 290–6(1939).—An illustrated description of present developments. C. C. Davis

Physiology of naphthoquinones and tannins in plants. Walter Lang. *Pharm. Zentralhalle* **80**, 713-16(1939).—A preliminary study has been inaugurated on the relations obtaining in the quinone metabolism of certain plants, notably between naphthoquinones (juglone) and tannins. In all probability, tannin formation is definitely promoted by light, without which carbohydrate provision fails to effect this synthesis, while juglone is a building stone of the *Pterocarya* tannin. W. O. E.

Variations in chemical composition of leaves (of tobacco) according to position on the stalk. T. R. Swanback. *Conn. Agr. Expt. Sta.* (New Haven), *Bull.* **422**, 22–6(1939); *Tobacco Substa. Windsor*, **1938**, *Rept.*—There is a gradual and regular increase in the percentage of total N leaf by leaf from bottom to top. The uppermost leaves contain about 3 times as much N as the lowest. Ca is highest in the lowest leaves and decreases regularly to the top of the plant. The larger percentage of Ca in the older leaves is probably due to the higher percentage of cell-wall materials and the longer period of pptn. of the Ca into insol. salts, a form unsuitable for translocation. Mg follows the same course as Ca. There is only 1/3 as much Mg in the top leaves as in the lower fillers. K also shows a tendency to decrease at the top of the plant but the trend is not so definite. A wet season is always reflected in higher K and lower Ca in the tobacco leaves. C. R. Fellers

Influence of temperature on sensitivity to α-rays. M. Klusakova. *Compt. rend. soc. biol.* **132**, 280–2(1939).—Onion epidermis cells were almost as sensitive at 8° as at 28° to the lethal action of Po α-rays. L. E. Gilson

Formation of radiotoxins after irradiation with α-rays. F. Herčík and J. Zacek. *Compt. rend. soc. biol.* **132**, 283–4(1939); cf. *C. A.* **33**, 2940[8].—Expts. with onion epidermis gave inconclusive results. L. E. Gilson

Action of caffeine on vegetable cells. L. Montemartini. *Boll. soc. ital. biol. sper.* **14**, 618–19(1939).—Caffeine stimulated the cells of *Cladophora insignis* when used in concns. less than 0.05%. This action occurred best when the conditions of light and temp. were least favorable to photosynthesis. Helen Lee Gruehl

Inheritance of chemical composition by hybrids between N. tabacum and N. glauca. V. D. Tikhvinskaya. *Compt. rend. acad. sci. U. R. S. S.* **24**, 791–3(1939)(in English).—Growth expts. with seeds of *N. tabacum* 44/39 Dubeque and *N. glauca* and the hybrid F_1 with fertilizers NKP (2:2:1) and 2.3 g. of NH_4NO_3 dissolved in H_2O and supplied to the plants from below on June 30th were carried out, the vegetation period lasting 78, 120 and 85 days. The data (in table) of the chem. analysis of the leaves show that the hybrid plants approach *N. tabacum* in the content of total and protein N; the alkaloids are transmitted from *N. glauca*. The leaves of the hybrid and of *N. glauca* decrease in the alkaloid pptd. by silicotungstic acid until its content is only tenths and even hundredths of 1%; but the total of alkaloids increases quickly both in the hybrid and in *N. glauca*. Toward the end of the 2nd 10 days after flowering the amt. of alkaloids in the leaves of the hybrid plants is twice its former value. This means that the alkaloid of *N. glauca*, anabasine, is hereditarily transmitted. 7 references. A. H. Krappe

Action of chemical reagents on the inhibition of potato sprouting. G. I. Grechka. *Biokhimiya* **4**, 121–32(1939).—EtOH, in concns. of 2.5 ml. per 20 l. of space, has the property of inhibiting potato sprouting. The oxidase activity remains unchanged, whereas the catalase activity is somewhat raised. Once the alc. vapors are removed from the atm., protection from sprouting is lost. Treatment of potato tubers with a mixt. of chlorinated hydrocarbons (a by-product of Russian factories), in concns. of one to a thousand, for 24 hrs., inhibits sprouting for 2 months. H. Priestley

Effect of low temperatures on the reversibility of enzymic reactions as related to the hardiness of the plant. N. M. Sisakyan and B. A. Rubin. *Biokhimiya* **4**, 149–53(1939).—In nonhardy varieties of apple trees, the shift of enzymic equil. in the direction of hydrolysis and the loss of synthetic capacity occur at a higher temp. level than in the hardy sort. At low temps., the plant perishes because of this irreversible hydrolysis shift. H. Priestley

Participation of phosphatase in the synthesis of sucrose. A. L. Kursanov and N. N. Kryukova. *Biokhimiya* **4**, 229–40(1939); cf. *C. A.* **33**, 683[9].—Infiltration into chicory leaves of a mixt. of glucose, fructose and NaH_2PO_4 leads to an energetic formation of org. P compds. and sucrose. The synthetic action of invertase in the leaves of P-deficient sugar beets is only about a third of the normal value; infiltration of NaH_2PO_4 causes a lively sucrose synthesis. During P starvation, the leaves of the sugar beet contain only about half the normal amt. of hexose monophosphate. The amt. of hexose diphosphate is only slightly lower. Plants suffer during P starvation because of their inability to form sufficient hexose monophosphate, thus sharply decreasing sucrose synthesis. In most plants, the synthesis of sucrose from fructose is

much more vigorous than from glucose or invert sugar. The rate of sucrose synthesis in plants in many cases is limited by the amt. of fructose monophosphate present. H. Priestley 1

Sources of vitamin C formation in the living plant cell. B. A. Rubin, E. V. Artsikhovskaya, N. S. Spiridonova and O. T. Lutikova. *Biokhimiya* 4, 260–7(1939).—The ascorbic acid content increased when wheat sprouts were infiltrated by a soln. of sucrose. In a N atm., no increase was observed, whereas in O, the increase in ascorbic acid as a result of the infiltrated sugar was 2.5 times the normal content. **Oxidation processes in living tissues and the changes in their vitamin C content.** *Ibid.* 268–75.—Formation of vitamin C in germinating seeds is increased when the cells are supplied with a good source of O. Depressing the oxidative processes leads to a fall in the vitamin C content. H. Priestley 2

Differences in the dehydrogenase content of pea seeds. E. V. Dodonova. *Biokhimiya* 4, 342–51(1939).—As is well known, marked qual. differences are shown by dehydrogenase obtained from various sources in the plant world. Differences in enzymic activity of various strains of peas are discussed. Wrinkled peas have a higher dehydrogenase content than round peas. On hybridization, the F_1-hybrids contain an amt. of dehydrogenase intermediate in value to that of the parents. Ripe pea seeds show a lower dehydrogenase content than unripe seeds. H. Priestley 3

Localization of some chemical constituents in the vegetable cell. II. A. M. Goldovskiĭ and M. Z. Podol'skaya. *Biokhimiya* 4, 352–5(1939); cf. *C. A.* **32**, 3785⁹.—The carotenoids in the sunflower seeds are localized in the gel (nonlipoid) phase. During the mfg. process, the carotenoids may pass from the gel phase into the oil. H. P. 4

Action of potassium-nitrogen nutrition on the carbohydrate metabolism of the rubber plant Taraxacum koksagyz Rodin. A. Kalinkevich. *Biokhimiya* 4, 381–91 (1939); cf. *C. A.* **33**, 3952⁴.—The changes in the amt. of various sugars in the leaves and roots of kok-sagyz were detd. at various phases of development. An abundance of N and K brings about an increase in the sugar content. H. Priestley 5

Importance of partial proteolysis of root proteins for the hardiness of clover. V. V. Koperzhinskiĭ. *Biokhimiya* 4, 404–10(1939).—The hardy variety of clover is characterized by the ability to attain partial proteolysis of the protoplasmic proteins. The simpler proteins formed are less subject to denaturization on freezing. H. P. 6

The specific rotation of wheat and legume starch. M. I. Knyaginichev and Yu. K. Palilova. *Biokhimiya* 4, 423–33(1939).—The starch from primitive varieties with scaly grain has a lower sp. rotation (199.8°) than the starch of cultivated varieties with naked grain (204.0°). The starch from legumes has a lower sp. rotation (192.7°) than wheat starch. The value of the sp. rotation runs parallel with the degree of evolutionary development. H. Priestley 7

New investigations on the growth of the plant cell wall. Studies on the growing cotton hairs. Kurt Hess. *Klepzig's Textil-Z.* **42**, 629–32(1939).—Chem. and phys. studies reported show that the growth of the cell wall during the stage of the lengthening of the cell differs fundamentally from that during the stage of the thickening of the wall. The noncelluloses (waxes, phosphatides, proteins, etc.) are most active during the elongation stage (primary wall) and exert very little influence during the formation of the secondary wall. Cellulose is present in the primary wall only in small amts. When the noncelluloses are removed the cellulose arranges itself in the primary wall spontaneously in accordance with the lattice structure of the secondary wall, while the primary wall acquires the characteristic properties of thick walls. This artificial production of secondary-wall cellulose with the properties of ripe walls from irregularly arranged primary cellulose makes it likely that in the primary wall the cellulose formation is retained in a state which is passed *in vivo* during the formation of the secondary-wall cellulose. The mechanism of cellulose formation, therefore, involves the production of cellulose without any lattice structure and the subsequent action of lipoid-sol. substances which bring about the migration of the producing phase and thus form the lattice structure that is responsible for the properties of the secondary wall. Leopold Scheflan 8

Photoperiodic responses of several varieties of soybeans. H. A. Borthwick and M. W. Parker. *Botan. Gaz.* **101**, 341–65(1939); cf. *C. A.* **33**, 6371¹.—A study of floral differentiation was made upon 13 varieties of soybeans with 9 different photoperiods (8–24 hrs.). All varieties which normally mature seed in the field in 105 days or less initiated flower primordia under all photoperiods. Varieties requiring 125–175 days to mature seed did not initiate primordia under photoperiods longer than 16 hrs. The initiation of primordia in many varieties under continuous light showed that darkness is not a necessary condition but initiation proceeded more rapidly if there was a daily alternation of light and dark. Chem. analyses of the varieties Agate (initiating primordia under a 16-hr. photoperiod) and Biloxi (not initiating primordia under a 16-hr. photoperiod) were made weekly. Agate contained less total and sol. N and more carbohydrates than Biloxi. Starch reached a max. in Agate at 3 weeks and declined with age but in Biloxi a max. had not been reached in 6 weeks. The max. carbohydrate content in Agate occurred at the time floral initiation was beginning. J. T. S. 9

Effects of temperature, calcium and arsenious acid on seedlings of Poa pratensis. Aubrey W. Naylor. *Botan. Gaz.* **101**, 366–70(1939).—$CaCO_3$ had a depressing effect on germination of seed and on yield of dry matter up to 35 days of growth but at 90 days $CaCO_3$ had increased top growth by 33%. Temp. is more important than $CaCO_3$ in producing root growth which was greater at 15° than at 25°. Under conditions of high temp. (22–25°) liming shortly after germination may be most favorable for the establishment of a good stand. A concn. of arsenious acid of 0.01% improved germination and growth but concns. above 0.05% were toxic. Higher concns. of arsenious acid are required to kill the growing point than the leaves. Arsenious acid has a greater toxicity to *Poa pratensis* seeds than to some other grass seeds. J. T. Sullivan 10

Comparison of growth responses induced in plants by naphthaleneacetamide and naphthaleneacetic acid. John W. Mitchell and Wm. S. Stewart. *Botan. Gaz.* **101**, 410–27(1939); cf. *C. A.* **33**, 9371².—The growth responses in a no. of plants to naphthaleneacetamide (I) and to naphthaleneacetic acid (II) applied by different methods are described. Application of either I or II resulted in mobilization of solid materials toward the treated region. Mobilization was assocd. with secondary thickening in plants treated with I and with cellular proliferation when treated with II. J. T. Sullivan 11

Growth substances and gametic reproduction by Phycomyces. Wm. J. Robbins. *Botan. Gaz.* **101**, 428–49 (1939).—The intensity of gametic reproduction of *Phycomyces blakesleeanus* upon an agar medium contg. dextrose, asparagine, mineral salts and thiamine was decreased with the greater distance between the inocula and by larger amts. of asparagine. It was favored by increasing agar concn. and by the addn. of plant exts. The beneficial materials in agar could be extd. in part by dil. MeOH or by aq. pyridine. The addn. of plant exts. overcame in part the inhibitory effect of the larger amts. of asparagine. Little gametic reproduction was obtained at 25° in a liquid medium contg. the same nutrients unless a plant ext. was added. Conclusion: Growth substances in addn. to thiamine are concerned in the reproduction. J. T. S. 12

Evidence for auxin production in isolated roots growing in vitro. J. Van Overbeek. *Botan. Gaz.* **101**, 450–6 (1939); cf. *C. A.* **32**, 7961⁸; **33**, 5025³.—Isolated pea roots were cultivated *in vitro* under sterile conditions. Each week the roots were subcultured with the 10 mm. tip only and the remainder, approx. 700 mm., was discarded. The total amt. of auxin extd. from the discarded bases for 20 weeks was 9 times that extd. from the initial tip from which the cultures originated. At the end of 34 weeks the roots contained as much as 1000×10^{-6} γ indoleacetic acid equivs. of auxin per root. J. T. Sullivan 13

Vernalization of Marquis wheat and other spring cereals. D. J. Wort. *Botan. Gaz.* **101**, 457–81(1939).—Two microchem. methods were used to diagnose the vernalized state of Marquis wheat. Treatment of embryos with $FeCl_3$, washing, and then treating with $K_4Fe(CN)_6$ showed a change in the ability of the growing point to reduce $FeCl_3$ as vernalization progressed. A shifting of the isoelec. point of the embryo tissues from pH 5.32 to 4.88 upon completion of vernalization was detected by the use of McIlwain's buffers and staining with eosin and methylene blue. The results of treatments of wheat, oats, barley and rye with 125 different combinations of vernalization factors are described. J. T. Sullivan 1

Further experiments on the relation of vitamin B_1 to the growth of green plants. James Bonner and Jesse Greene. *Botan. Gaz.* **101**, 491–500(1939); cf. *C. A.* **32**, 9185[5].—The addn. of vitamin B_1 (I) to plants in culture increased the dry wt. The effect is lasting rather than temporary. Plants which did not respond to I contained more I in the leaves than plants which did respond to its addn. It is suggested that the amt. of I synthesized by the leaves of a given species regulates its response to addns. of I and that the leaf content may be used to diagnose whether or not addn. of I would promote growth. The leaves of plants supplied with I contained more I than plants not supplied. J. T. Sullivan 2

Chemistry and bromatology of mangarito and mandioquinha. Maria Conceição Fonseca Monteiro and Laura Abrantes Bueno. *Arquiv. hig. saúde pública* (São Paulo) **4**, No. 6, 69–71(1939).—Tubers of *Caladium sagittifolium* V. contain in the dry substance ash 4.87, sugar (traces), starch 71.68, fat 0.86, nitrogenous substances 12.36, cellulose and undetermined matter 10.21%. The normal moisture content is 67.44%; the corresponding figures for tubers of *Chaerophyllum bilbosum* L. are 4.30, traces, 79.94, 0.66, 5.10, 6.98 and 68.45%. O. W. W. 3

Excretion of thiamine and biotin by the roots of higher plants. P. M. West. *Nature* **144**, 1050–1(1939).—This work was designed to explain the higher microbial population in the soil in the immediate vicinity of the roots of higher plants. One hundred representative bacteria were isolated from each of the rhizospheres of flax grown in the green house and of tobacco grown in the field. A similar no. of control organisms was isolated from soil outside the zone of root influence. All organisms were then grown on 2 media, one of which contained cysteine, *m*-inositol, thiamine, β-alanine, nicotinic acid and biotin, the other of which did not. In every case those organisms that depend on previously synthesized growth factors were markedly more abundant in the rhizosphere. Flax seeds were grown under sterile conditions in water culture. The solns. were concd. and assayed for thiamine by the *Staphylococcus aureus* test and for biotin by *Rhizobium trifolii*. Measurable amts. of both substances were found. J. J. Willaman 4

Analysis and integration of various auxin effects. I. F. W. Went. *Proc. Acad. Sci. Amsterdam* **42**, 581–91 (1939).—A discussion of the mechanism of action of growth hormones. Four sep. reactions are recognized: preparatory reactions for both growth and for root formation, the growth reaction proper and root formation proper. II. *Ibid.* 731–9.—Six stages are recognized in the growth of a cell, and each of these is occasioned by the interaction of several substances and not by the action of a single growth substance. These interactions are shown in a diagrammatic scheme. J. J. Willaman 5

Value of plasmolytic methods for the demonstration of the active asparagine intake by Vallisneria leaves. W. H. Arisz and P. J. S. van Dijk. *Proc. Acad. Sci. Amsterdam* **42**, 820–31(1939).—By analysis of leaves for N before and after submerging in asparagine soln. and by measuring the osmotic pressure of the cells by incipient plasmolysis it was shown that asparagine is taken up by the leaf and that it is almost quantitatively responsible for the increase in osmotic pressure. The presence of O was required for the uptake of asparagine, but not for glycerol. J. J. W. 6

Observations in plants on the production of tumorous growths simulating those of cancer. M. M. Galiardo. *Univ. Philippines Nat. and Applied Sci. Bull.* **7**, 59–66 (1939).—Tumors were induced on 6 species of trees by cutting off the main stem, by sprinkling the branches with human urine, or by placing excessive amts. of animal excrements under the tree. G. believes that tumors are caused by excessive nutrients in the tissues, and that these nutrients, probably nitrogenous, must be added to the list of plant carcinogenic substances. J. J. W. 7

E—NUTRITION

PHILIP B. HAWK

The effect of treated fats on vitamin A potency. R. T. Harrelson, P. Mabel Nelson, Belle Lowe, H. C. Dyme and V. E. Nelson. *Iowa State Coll. J. Sci.* **13**, 353–64 (1939).—Some oleomargarines and some coconut oils after heating to 102–5° in thin layers for 24 hrs. destroyed vitamin A in butterfat to which they were added, and a few other heated samples did not. Rancid fats also destroyed vitamin A. Peroxides are not the only destructive factors. Heating below 80° did not produce the destructive effect. Addn. of heated fats to doughs to be baked may destroy vitamin A. The significant factors are not completely known. F. E. Brown 16

The relation of the vitamin B complex to the nutrition of domestic animals. Aaron Arnold and C. A. Elvehjem. *J. Am. Vet. Med. Assoc.* **96**, 56–61(1940).—A review with 48 references. Rachel Brown 17

Nitrogen metabolism and vitamin B_1 under various conditions of nutrition in birds. B. A. Lavrov and Mme. N. S. Yarusova. *Bull. soc. chim. biol.* **21**, 1139–50(1939); cf. *C. A.* **32**, 6698[8].—When pigeons were fed only raw buckwheat their N balance was very slightly neg., but if the buckwheat was heated to destroy vitamin B_1 the N balance became strongly neg. In pigeons deprived of all food vitamin B_1 had no effect on the N balance. In pigeons on a protein-free starchy diet absence of B_1 provoked a marked N excretion and hastened the appearance of polyneuritis, but if sufficient B_1 was fed the N catabolism was decreased to a low level and life was greatly prolonged. L. E. Gilson 18

Relation between acetylcholine and vitamin B_1. V. Erspamer. *Boll. soc. ital. biol. sper.* **14**, 655–6(1939).—Vitamin B_1 had no effect on the fall in blood pressure produced by acetylcholine. On living organs concns. of vitamin B_1 less than $^1/_{100,000}$ did not influence the action of acetylcholine while greater concns. were antagonistic. Injections of 30–100 mg. aneurine/kg. (not lethal) followed 19

by nonlethal doses of acetylcholine caused death whereas lethal doses of aneurine followed by lethal doses of acetylcholine inhibited the toxic effects and retarded death. Helen Lee Gruehl

Ascorbic acid and vagal excitability. Lorenzo Cioglia and Francesco Infantellina. *Boll. soc. ital. biol. sper.* **14**, 736–8(1939).—Ascorbic acid caused an elevation of the threshold of excitability in the peripheral branches of the vagus and a lowering of the threshold in the central vagus. Helen Lee Gruehl

Bacillary dysentery developing in monkeys on a vitamin M-deficient diet. Martha Janota and G. M. Dack. *J. Infectious Diseases* **65**, 219–24(1939).—Captive monkeys (*Macaca mulatta*) that are carriers of *Bact. dysenteriae* (Flexner) generally developed bacillary dysentery on a vitamin M-deficient diet. Some animals are more readily depleted than others. Monkeys on diets deficient in vitamin M and one or more of the following, A, C or D, did not react differently as far as colon lesions and infection with *Bact. dysenteriae* were concerned than did monkeys on only the vitamin M-deficient diet. J. H. Lewis

Deficiency of vitamin B_1 in man as determined by the blood cocarboxylase. Robert Goodhart and H. M. Sinclair. *J. Biol. Chem.* **132**, 11–21(1940); cf. *C. A.* **33**, 5014[9], 8272[7].—The amt. of cocarboxylase in the blood in general runs closely parallel to the total amt. of vitamin B_1 and its detn. provides a reasonably accurate index of the degree of satn. of the body with cocarboxylase and vitamin B_1. The only exceptions are the rare cases in which the ability of the tissues to phosphorylate the vitamin is apparently diminished, the cases in which the blood cell count is greatly increased (polycythemia vera or myeloid leucemia) and patients who have recently received intensive vitamin B_1 therapy over a very short period of time. Deficiency of vitamin B_1 is assocd. with cases of anemia, of subacute combined degeneration of the cord and of certain psychiatric disorders and there is an etiological relationship between vitamin B_1 deficiency and "alc." neuritis, nutritional neuritis and some cardiovascular disturbances. A definite deficiency of vitamin B_1 is not uncommon among hospital patients in England, but it is emphasized that vitamin deficiencies in man are almost always multiple and are therefore usually inadequately treated by administration of a single pure vitamin. A. P. Lothrop

The relation of vitamin B_6 and pantothenic acid to factor W studies. Simon Black, D. V. Frost and C. A. Elvehjem. *J. Biol. Chem.* **132**, 65–75(1940); cf. *C. A.* **32**, 981[6].—Purified prepns. of factor W still contain considerable amts. of pantothenic acid, and part of the growth-promoting activity of the prepns. is due to this vitamin, but the prepns. also contain at least 1 other factor which is required in addn. to pantothenic acid for normal growth in the rat. The factor W assay ration previously used was deficient in vitamin B_6 and significant growth responses are obtained when synthetic vitamin B_6 is added to that ration plus factor W concentrates. The original factor W has been sepd. by an acid-ether extn. into 2 factors, one of which is pantothenic acid. It is suggested that the term, factor W, should be reserved for the factor in the residue. A procedure for the prepn. of highly purified factor W concentrates is described. A. P. Lothrop

The relation between factor U and vitamin B_6. E. L. R. Stokstad, P. D. V. Manning and R. E. Rogers. *J. Biol. Chem.* **132**, 463–4(1940); cf. *C. A.* **32**, 9198[8].—Factor U is a H_2O-sol. growth factor required by chicks receiving a diet consisting essentially of polished rice and washed fish meal supplemented with riboflavin and the chick antidermatosis factor. It has now been shown that this diet is deficient in 2 factors, 1 of which is vitamin B_6. The greater part of the unknown factor U which is present in yeast is adsorbed on fuller's earth, the eluate showing some activity and the filtrate being entirely inactive. A. P. Lothrop

Anemia in chicks caused by a vitamin deficiency. Albert G. Hogan and Ernest M. Parrott. *J. Biol. Chem.* **132**, 507–17(1940); cf. *C. A.* **30**, 750[7].—When chicks receive a simplified ration contg. the well-recognized vitamins and in addn. a 95% alc. ext. of dried liver, they grow slowly and become anemic. The red cell count, the percentage of hemoglobin and the red cell vol. are all decreased. The amt. of hemoglobin per cell is increased and the cells are longer and wider than normal and are less fragile and the vol. of the individual cells is increased. The antianemic agent has not been identified with any vitamin previously described. It belongs to the old vitamin B complex and has been designated as vitamin B*c*, the *c* being added because the substance is essential for the chick. A. P. Lothrop

Essential fat acids, vitamin B_6 and other factors in the cure of rat acrodynia. H. A. Schneider, H. Steenbock and Blanche R. Platz. *J. Biol. Chem.* **132**, 539–51(1940).—Acrodynia, as it is known in the rat, can be cured by the so called "essential fat acids" and this action is independent of vitamin B_6. It can also be cured by rice bran concentrate and this action is independent of fat acids but dependent upon vitamin B_6 plus a 2nd "accessory factor" which is present in the filtrate from fuller's earth treatment of rice bran concentrate. Vitamin B_6 both in crude prepn. and in cryst. form has only a temporary effect on acrodynia in the absence of the 2nd factor. The Burr and Burr syndrome (*C. A.* **23**, 4501) could be produced by the addn. of dried brewers' yeast to the acrodynia-producing diet and was cured by both "essential fat acids" and rice bran concentrate. Gradations between the severe symptoms of acrodynia and the mild symptoms of the Burr and Burr syndrome were obtained by feeding increasing amts. of yeast. A. P. Lothrop

Vitamin A deficiency. III. Blood analysis correlated with a visual test. L. B. Pett and G. A. LePage. *J. Biol. Chem.* **132**, 585–93(1940); cf. *C. A.* **34**, 1058[7].—There is a definite correlation between the vitamin A level in the blood and the Pett visual test for vitamin A deficiency. Vitamin A in blood was detd. by a modification of Lindqvist's procedure (*C. A.* **33**, 2949[2]); an ordinary microcolorimeter was used. A. P. Lothrop

Vitamin deficiencies and the nervous system. Geo. R. Cowgill. *Yale J. Biol. Med.* **12**, 205–11(1939).—A consideration of the contributions of animal experimentation. G. H. W. Lucas

Vitamin A and organic metabolism. I. The action of vitamin A on protein metabolism in normal persons and in patients with liver disease, with special reference to deaminization and urea formation. Marco Pescarmona. *Arch. sci. med.* **68**, 547–62(1939).—The amino acid and urea N in blood and urine in persons with and without liver disease was studied during a 12- to 15-day treatment with 120,000 units of vitamin A daily. The blood showed only insignificant changes, but in the urine the amino acids decreased while urea was augmented. The difference was more marked in hepatic patients. A. E. Meyer

Role of vitamins and calcium in the diet in the utilization of proteins. K. P. Basu and K. Gupta. *J. Indian Chem. Soc.* **16**, 449–59(1939).—Absence of vitamins A, B_1, B_2 (all heat-stable factors), B complex or D from the diet of rats for a short time has little or no effect on the digestibility of casein. However, absence of any of these vitamins increases the percentage of digested casein that is retained, i. e., the biol. value. Autoclaving casein decreases the biol. value and the digestibility; while the absence of Ca has no effect on the former but increases the latter. Dorothy A. Meyer

The William Henry Welch lectures. I. New light on the biological role of vitamin E. Herbert M. Evans. *J. Mt. Sinai Hosp., N. Y.* **6**, 233–44(1940).—Review with 41 references. J. Pinchack

Digestibility of oxidized soybean oil (Palsgaard emulsion oil). H. R. Kanitz. *Z. Untersuch. Lebensm.* **78**, 385–6(1939).—The material sol. in petr. ether in the excreta of 2 groups of rats during a preliminary bread diet period was detd. When 84.1 mg. and 336.4 mg. of oxidized soybean oil (I) per day, per rat were added the amts. of excreted fat increased to, resp., 7.67 and 8.83% based on the resp. amts. of I fed. The digestibility was 91.2–92.3%. This corresponds to the digestibility of cacao fat. M. M. Piskur

Oxygenase properties of carotene. O. Ya. Borodina. *Biokhimiya* 4, 356–66(1939).—Carotene functions as an oxygenase in the presence of a peroxidase of plant or animal origin. Unsatd. vegetable oils inhibit the O action of carotene. H. Priestley

The effect of vitamin A upon hair and nail growth. Bruno Schwemmler. *Münch. med. Wochschr.* 86, 1228–7 (1939).—Vitamin A stopped loss of hair in patients suffering from hyperthyroidism after 8 to 10 days, and increased both hair and nail growth. Appreciable growth was observed after 24,000 international units was given twice daily. When 28,000 to 48,000 units 3 times daily was given, the av. increase in growth of hair was between 1.2 and 1.5 mm. Vitamin A in thyrotoxicosis inhibits the falling out of hair by fixing the hair to the follicle and favorably affecting cornification in the hair follicle and nail bed. Vitamin A also has a sedative action and in these patients sleep was deeper and more restful. M. M. R.

Prophylaxis and therapy of vitamin B hypovitaminoses with concentrated yeast (Philocytin). Friedrich Diehl. *Münch. med. Wochschr.* 86, 1301–5(1939).—Concd. yeast (4–5 g. 2 or 3 times a day) administered after meals gave good results in vitamin B deficiency. This prepn. supplies the organism with all factors of the vitamin B complex and is indicated in disturbances of metabolism due to long-lasting fever and Basedow's disease, polyneuritis of alcoholism and pregnancy, and myelosis. Maurice M. Rath

Vitamin C balance in tumor patients. Silvio Antes and Clemente Molo. *Schweiz. med. Wochschr.* 69, 619–23 (1939). In 62 patients with tumor diseases, there was severe vitamin C deficiency as detd. by examn. of the urine by Jezner and Niederberger's titration method. In spite of a considerable deficiency, no scorbutic symptoms were ever noted. The hypovitaminoses among patients with malignant tumors are apparently the result of cachexia and do not depend upon alimentary injuries. Administration of vitamin C to these patients can noticeably reduce the deficiency symptoms. Maurice M. Rath

Vitamin C requirement of the child. W. Tobler *Schweiz. med. Wochschr.* 69, 677–9(1939).—A review. Maurice M. Rath

Heat-labile factors necessary for the proper growth and development of cats. F. M. Pottenger, Jr., and D. G. Simonsen. *J. Lab. Clin. Med.* 25, 238–40(1939).—In a study covering a period of 3 yrs., kittens born of parents fed cooked food (cooked meat, dry feed raw milk and cod-liver oil) showed many deficiencies, such as low birth wt., poor dental development, and disturbance of genital development, when compared to a control group of kittens born of parents fed raw food. The defects were increased in the second and third generations and a study of the microscopic sections of the lungs of this group showed hyperemia, some edema, and partial atelectasis, while those most deficient showed bronchitis and pneumonitis. The third-generation kittens of parents fed cooked food never survived more than 2 months. H. W. Robinson

Ultraviolet irradiation and vitamin C° metabolism. Claus W. Jungeblut and Rose R. Feiner. *J. Lab. Clin. Med.* 25, 263–9(1939).—The levels of vitamin C in the brain, liver, spleen, and adrenal gland of guinea pigs, rabbits and rhesus monkeys exposed to prolonged ultraviolet irradiation, that failed to produce any evidence of erythema on the exposed skins, were identical with those in the same organs of control animals. There was a drop in the content of vitamin C in these organs when a superficial burn was produced on the skin of guinea pigs before exposure. A derangement of vitamin C metabolism by excessive doses of radiant energy apparently takes place only when there is injury to the tissues. H. W. R.

Whey as a source of vitamins and vitamin products. G. C. Supplee. *Ind. Eng. Chem.* 32, 238–40(1940).—Removal of butterfat, casein, lactalbumin, Ca, P and lactose from milk by the usual methods leaves a soln. of mineral substances, small amts. of protein to which sterols are bound, residual lactose and water-sol. vitamins. It was first shown that the addn. of 7–12% of this fraction to a basal ration of butterfat, casein, lactose, minerals and cod-liver oil is required for normal growth, reproduction, lactation and rearing of the young. Later studies showed that a combination of equal parts of milk vitamin fraction and crude rice polishings is a sufficient addn. to a basal ration of purified protein, dextrin, mineral salts, Crisco and cod-liver oil to maintain normal development and high fecundity in both sexes of 8 successive generations of white rats. In a study extending from 1923 to 1936, over 4000 litters of white rats were started from a single colony. During the first 7 years of this period fluid whole milk (*ad lib.*) was a part of the basal ration of ground whole yellow corn, linseed meal, crude casein, ground alfalfa leaf meal, NaCl and Na_2CO_3. The av. no. per litter was 7.058. During the following 6 years, whole milk powder plus milk vitamin concentrate replaced the fluid milk. The av. no. per litter uniformly increased annually to 8.377 for 1936. Vegetable, butterfat, meat and cereal supplements and ultraviolet irradiation had failed to halt the progressive decline in fertility and ability of the mother to raise the young. The record litter was 23, obtained in 1935. The following factors have been directly identified in whey: G, B_1, B_6, K, provitamin D, and the estrogenic hormone; E and W are assumed to be present. Pptd. lactalbumin carries 7% lipide matter, 40–50% of which is cholesterol, activatable to a D potency of 1000 U. S. P. units per g. The remaining lipide has substantial K activity, as does also the dealbuminized whey. The following supplements were found to be equiv. in protecting rats from acrodynia: whey concentrate 200–300 mg., dry yeast 50–100 mg., water-sol. concentrate from rice polish 35–50 mg., fluid whole milk 4–5 cc., per day. Whey is so rich in vitamin G that it has become a source of com. quantities of the cryst. product. H. K. Salzberg

Seasonal variations in the vitamin A content of certain visceral organs of the geelbek or Cape salmon (Atractoscion aequidens C. and V.). Christopher J. Molteno and Wm. S. Rapson. *Biochem. J.* 33, 1390–3(1939).—The total vitamin A of the liver of this fish decreased at the onset of intensive feeding and then gradually increased. The amt. of vitamin A in the visceral oils was directly related to the oil content of the viscera. There was a direct relation between the amt. of oil in the liver and its iodine value, which varied inversely with the percentage of vitamin A in the oil. The results were in accord with the view that vitamin A is assocd. with the process of fat assimilation in the geelbek. E. W. Scott

Vitamin P. Harold Scarborough. *Biochem. J.* 33, 1400–7(1939).—The evidence upon which the existence of vitamin P is based is reviewed; on the basis of the published work there is no conclusive proof of its existence. However, in human subjects suffering from multiple vitamin deficiency the capillary fragility was increased. Orange and lemon juices and certain exts. from them contained a substance, flavanone in nature, which increased the resistance of capillary walls to pressure. This substance was not ascorbic acid. E. W. Scott

Inhibition of experimental production of liver cancer by feeding liver. A study in nutrition. Waro Nakahara, Kazuo Mori and Tadasi Huziwara. *Gann* 33, 406–28 (1939); cf. *C. A.* 33, 5899².—Each group of normal albino rats was maintained upon one of the following diets in which 0.2 to 0.6 g. of dimethylaminoazobenzol (butter yellow) was mixed for each kg. of food. It was supplemented with a small slice of fresh carrot every other day. The diets tested for the preventive effect upon production of liver cancer were: polished rice + dried beef liver; polished rice alone; polished rice + purified protein; polished rice + butter; polished rice + inorg. salt mixt.; polished rice + vitamin B_1; polished rice + vitamin B_6; polished rice + nicotinic acid; polished rice + liver eluate (as vitamin B_2); polished rice + nonadsorbable liver filtrate (as vitamin L and factor W); and polished rice + purified protein + butter + salt mixt. + vitamin B_1 + nicotinic acid + liver eluate and filtrate. In most of the expts., all rats living for 150 days were killed for examn. The results showed that feeding of liver prevented the hepatoma production. At the 200th day, the liver of the liver-fed rats showed slightly uneven surface and slight

proliferation of connective tissue. From 50 to 100% of the rats on the other diets showed liver cancer. K. S

The effect of vitamin B_1 on blood calcium. Heiki Lee. *J. Chosen Med. Assoc.* **29**, 2113–19(English abstr. 137–8) (1939).—One hr. after injection of 2–3 mg. B_1 into healthy men or dogs, serum Ca rises 1.4–0.9 mg. per 100 cc. and returns to normal after 3 hrs. This effect of B_1 on serum Ca occurs also in splenectomized animals, but not in the parathyroidectomized; this suggests that B_1 must act through the parathyroid. S. Tashiro

The effect of diet on the severity of scurvy. H. Yokohama. *J. Chosen Med. Assoc.* **29**, 2256–306(German abstr. 143–4)(1939).—Severity of scurvy of guinea pigs fed with scurvy-producing diets depends upon the compn. of such diets. When the diet is rich in carbohydrate, scurvy is very mild. When fat dominates, it is very severe; with protein the severity is intermediate. S. Tashiro

Biological standardization of vitamin A. P. Tainsh and H. Wilkinson. *Chemistry & Industry* **1939**, 1051–2.—Rats fed on 2 basal diets, the Morgan and the British Pharmacopeia 1936, gave different responses to both vitamin A and to β-carotene. There was also a difference in liver storage and in fecal excretion of a carotenoid. T. and W. emphasize the importance of arriving at a basal diet free from these discrepancies. J. J. Willaman

F—PHYSIOLOGY

HOMER W. SMITH

Chemical nature of iodothyroglobulin. I. Abelin and A. Keller. *Helv. Chim. Acta* **22**, 1365–9(1939); cf. *C. A.* **28**, 1756[1].—Thyroid exts. of cattle, sheep and swine were freed from fat and connective tissue, finely chopped and shaken with an equal vol. of 1% NaCl soln. contg. 0.02% NaOH. After filtration the residue was similarly extd. and the combined filtrates were shaken 24 hrs. with satd. $(NH_4)_2SO_4$ soln. The thyroglobulin ppt. was freed from $(NH_4)_2SO_4$ by dialysis and stabilized by addn. of tricresol. The dialyzed soln. was filtered and brought to a pH of 6. After standing, a ppt. (I) formed which had an I content of 0.20–0.25%. The filtrate from the last pptn. was brought to a pH of 4, thereby pptg. a solid (II) contg. 0.4% I. From several thyroid extns. at a pH of 6 a product (III) contg. 0.1–0.14% I was obtained. I, II and III were H_2O-sol. and gave the ordinary protein and I reactions. They were further purified by a second pptn. at the appropriate pH. The total I content (*C. A.* **6**, 2901) of I, II and III was 0.28, 0.41 and 0.14%, resp., and the thyroxine I content (Blau, *C. A.* **27**, 5767; **29**, 5471[7]) was 21.19, 19.80 and 19.54%, resp., of the total I content. I, II and III were fed to rats. II and III produced practically the same increase in basal metabolism, while the increase caused by I was stronger and faster; no strict relationship between activity and I content could be deduced. A mixt. of 3 parts of II with 4 parts of I with resulting I content of 0.33% worked stronger and quicker than II which had a higher I content (0.41%). In 14 days the rats treated with I and II lost 29 g.; those treated with I or II lost 11–13 g. The mixt of I and II elevated the respiratory frequency from 88 to 126 per min.; I or II from 84 to 97. The activity of iodothyroglobulin (IV) cannot be interpreted as a mere sum of the physiol. effects of its I-contg. substituents. IV is not a homogeneous substance. IV can be sepd. into 3 fractions contg. organically bound I which varies in amt. from fraction to fraction. Each fraction contains thyroxine and the nature of the protein combined with the thyroxine seems to be of physiol. significance. David E. Adelson

Action of nicotinic acid on the erythrocytes and leucocytes of blood in normal animals. Antonietta Orrù. *Atti accad. Lincei, Classe sci. fis., mat. nat.* **29**, 333–43 (1939).—Intramuscular injection of nicotinic acid in rabbits, guinea pigs and doves produces cycles of increased production of red corpuscles. The reason the red corpuscles do not show a continued increase during the period of administration of nicotinic acid, is probably due to the exhaustion of some other factor concerned in the manuf. of erythrocytes, which must be replenished by diet before nicotinic acid can again accelerate the erythrocyte formation. Increase in lymphocyte formation was also noted on administration of nicotinic acid. A. W. Contieri

Tissue glutathione after extirpation of the spleen in dogs and rabbits. F. Šantavý. *Compt. rend. soc. biol.* **132**, 285–6(1939).—In dogs, one month after splenectomy the reduced and total glutathione of the blood, liver, lungs, pancreas, kidneys and adrenals showed a considerable decrease. In rabbits under the same conditions the glutathione showed no change or a slight increase. L. E. G.

Peripheral vascular action of estrogen, observed in the ear of the rabbit. Samuel R. M. Reynolds and Frances I. Foster. *J. Pharmacol.* **68**, 173–84(1940).—In ovariectomized rabbits the intramuscular injection of 250–10,000 units of estrone, estradiol, estradiol dipropionate or amniotin caused dilatation of the capillaries and venules of the ears. Arterial blood pressure was not affected. L. E. Gilson

Variations of blood calcium and phosphorus and the calcium:phosphorus ratio in the postoperative period after the removal of osseus tissue in otorhinolaryngology. Giulio Zanzucchi. *Boll. soc. ital. biol. sper.* **14**, 724–5(1939).—In the majority of cases studied Ca increased in the first 24 hrs. (av. increase 12.92%) and continued to increase during convalescence In general P diminished. The Ca/P ratio increased from an av. of 2.83 before the operation to 3.39 after 24 hrs. It reached 4.36 during convalescence. Helen Lee Gruchl

The correlation of physicochemical properties of serum with its effect on the growth of tissues in vitro. I. The hydrogen-ion concentration of diluted serum. W. S. S. Ladell. *S. African J. Med. Sci.*, Feb. Suppl. to Vol. 4, 35–40(1939) —Five series of estimations were made. In 2 of them the serum was dild. with Tyrode soln. and in 3 the diluent was "embryo ext.," representing 1 chick embryo in 5 cc. of saline. The serum used was stale horse serum, different samples being used for each series. The Tyrode used contained 0.05 instead of 0.1% of bicarbonate and more $CaCl_2$ and $MgCl_2$ (0.04 and 0.02% instead of 0.02 and 0.01%, resp.) than that usually advised, but has given good results. The pH of various mixts. of serum with Tyrode soln. has been measured with the quinhydrone electrode. The diln. curves obtained are similar to those obtained on mixing 2 simple buffers. The pH of the Tyrode was lower and that of the serum higher than the point at which growth of tissues *in vitro* is optimal. The addn. of a small quantity of serum to Tyrode brings the pH to the optimal value. These facts may be correlated with the effect of various dilns. of serum upon the growth of tissues *in vitro*. 15 references. W. R. Henn.

Studies in the physiology of the embryonic nervous system. IV. Development of acetylcholine in the chick

embryo. Zing Yang Kuo. *J. Neurophysiol.* **2**, 488–93 (1939).—Assays for acetylcholine (I) in chick embryos aged 2–12 days by all six methods proposed by Chang and Gaddum (*J. Physiol.* **92**, 17–18(1938)) revealed that I was present in chicks as young as 2.5 days and that the I content increased up to the 4th day and thereafter fluctuated randomly. The I content showed no correlation with the development of synapses or primary sympathetic trunks (found in the chick nervous system from the end of the 3rd day), with the *anlagen* of the primary sympathetic trunks (which do not arise earlier than the 6th day), or with the spontaneous reflex movements (which appear only from the 4th day, increase in frequency up to the 8th day and thereafter steadily decrease). The results suggest that I is not concerned with transmission of nerve impulses in the embryo Marion Horn

The vitamin C content of the cerebrospinal fluid. VIII. The passage of vitamin C into the cerebrospinal fluid in cases of injured blood-brain barrier. Mitio Kasahara and Ituo Gamino. *Z. ges. Neurol. Psychiat.* **166**, 733–4(1939); cf. *C. A.* **33**, 8743⁸.—When ascorbic acid was injected intravenously into adult male rabbits, it appeared in the cerebrospinal fluid to a greater extent after meningeal irritation by subdural injection of 0.5 cc. 3% aleuronate than it appeared before such meningeal damage. M. Horn

The xanthoprotein colorimetric value of nondeproteinized cerebrospinal fluid in comparison with the remaining humoral syndrome. Trude Bruns *Z. ges. Neurol. Psychiat.* **166**, 759–87(1939).—The quant. xanthoprotein test (Becher's method, cf. *C. A.* **20**, 1666) performed on 229 samples of human spinal fluid gave values which roughly paralled the results of the usual tests for spinal fluid pathology (lipoid, sugar, globulin, sedimentation, etc.). In general spinal fluids which were normal by the usual tests showed xanthoprotein values within normal limits (20–32 by Becher's scale), while those which were pathol. by the usual tests showed xanthoprotein values occasionally below the normal limit but usually far above, extending up to 1000. The highest xanthoprotein values were found in meningitis, untreated paresis and diabetic neuritis. However, 32 (14.5%) of the 229 samples showed no correlation between the results of the xanthoprotein and the other tests: in 11 cases the xanthoprotein values were elevated and the others normal, in 4 the xanthoprotein values were low and the others normal, and in 17 the xanthoprotein values were normal and the others pathol. It is suggested that the alterations in the tyrosine and tryptophan portions of the protein mols. in the cerebrospinal fluid, as shown by abnormal xanthoprotein values, may be the first signs of impending disturbance of the nervous system, and that the xanthoprotein test may hence provide a more sensitive indicator than the previously used tests for spinal fluid pathology. Marion Horn

The cerebrospinal fluid at various ages, with special reference to degeneration and senility. Carl Riebeling. *Z. ges. Neurol. Psychiat.* **167**, 133–46(1939).—Graphs are given, showing the changes in the protein, ammonia and water contents of the brain, and the protein, cell and ammonia contents of the cerebrospinal fluid from birth to senility, in man. Changes in the cerebrospinal fluid are discussed in relation to normal and pathol. changes in the brain. Marion Horn

Chemical changes in the blood vessels occurring with age. M. Bürger. *Z. ges. Neurol. Psychiat.* **167**, 273–80 (1939).—In human aortas from individuals aged 10–70 yrs., the cholesterol, Ca, total P and acid-sol. P contents increased with age, while the lipoid P and phosphatide contents did not change markedly and the total lipoid increased to 50 yrs. and then decreased somewhat. Aortas from cattle aged 1–15 yrs. and from horses aged 1–over 25 yrs. likewise showed an increase in cholesterol and Ca contents with age. The human, beef and horse aortas all showed decreases in N content and increases in the S/N ratio as the age increased. Apparently the protein in the aortas is replaced by chondroitinsulfuric acid in the aging process. Marion Horn

Radioactive phosphorus as an indicator of phospholipide metabolism. IX. The influence of age on the phospholipide metabolism of various parts of the central nervous system of the rat. The comparative phospholipide activity of various parts of the central nervous system of the rat. B. A. Fries, G. W. Changus and I. L. Chaikoff. *J. Biol. Chem.* **132**, 23–34(1940); cf. *C. A.* **33**, 9400⁹.—Phospholipide activity is highest in the rat on the day of birth in all parts of the central nervous system but there is a decline from birth until the rat attains a wt. of 50 g. which is so precipitous that when that wt. is reached the spinal cord retains only 5% of the activity present in the newborn animal. As growth proceeds beyond 50 g., the phospholipide activity decreases but at a much slower rate than between birth and 50 g. so that the spinal cord in a 200-g. rat possesses 20% of the activity present in a 50-g. rat. Only 15% of the activity is retained by the 300-g. animal. The forebrain, cerebellum and medulla also lose activity but the rate of decline is less than that which occurs in the cord. Phospholipide activity is highest in the spinal cord from birth to the time the rat reaches a wt. of 50 g. but after this the relative activities of forebrain, cerebellum and medulla rise steadily and by the time a wt. of 200 or 300 g. is attained they are as great in those divisions as in the cord or even greater. The phospholipide activity was studied by detg. the deposition of labeled phospholipide at 24- and 48-hr. intervals after administration of P^{32}. A. P. Lothrop

The biochemical behavior of lead. I. Influence of calcium, phosphorus and vitamin D on lead in blood and bone. Albert E. Sobel, Henry Yuska, David D. Peters and Benj Kramer. *J. Biol. Chem.* **132**, 239–65(1940).—The influence of the 3 dietary factors, Ca, P and vitamin D, must be considered in the biochem. behavior of Pb. Pb deposition in the bones can be explained by postulating that Pb, P and vitamin D form a system of Pb deposition analogous to the system of calcification. The addn. of Ca tends to remove P from the system for Pb deposition. The blood Pb values can be explained by assuming a relationship between blood Pb and dietary Pb to P ratios similar to the relationship between blood Ca and dietary Ca to P ratios. The influence of vitamin D on blood Pb is similar to its influence on blood Ca on corresponding dietary Pb to P ratios. Simultaneous Pb deposition and removal of Ca from bone is possible but increased calcification does not necessarily mean increased Pb deposition. It is concluded that Pb deposition is directed by a system of its own which is governed by the same laws as is Ca deposition but does not necessarily go in the same direction. The effect of Ca on the deposition of Pb is essentially competitive because it tends to remove P available for Pb deposition. Fifty references. A. P. Lothrop

Sulfonium reactions of methionine and their possible metabolic significance. Gerrit Toennies. *J. Biol. Chem.* **132**, 455–6(1940).—Methionine forms sulfonium compds. with MeBr or MeI which are H_2O-sol., neutral substances. The suggestion is made that the biol conversion of methionine into cystine might involve the formation of a sulfonium deriv. and the participation of hydroxyamino acids in the following manner: $HO_2CHNH_2(CH_2)_2SMe + HO_2CCHNH_2CH_2OH \rightarrow HO_2CCHNH_2(CH_2)_2S(Me)(OH)\text{-}CH_2CHNH_2CO_2H \rightarrow$ (by removal of MeOH and cleavage) $HSCH_2CHNH_2CO_2H$. Similar reactions may be postulated for hydroxyglutamic acid and threonine, and combinations of decarboxylation and ω oxidation could lead to the same final product. According to this hypothesis the —SMe group itself is an essential factor in the genesis of cystine from methionine. A. P Lothrop

Conversion of 3,17-etioallocholanedione into androsterone. Ralph I. Dorfman. *J. Biol. Chem.* **132**, 457–8 (1940); cf. *C. A.* **33**, 8749⁸.—Androsterone has been isolated from the urine of a man with evidence of deficient testicular secretion after feeding 100 mg. of 3,17-etioallocholanedione per day for 10 days. It thus appears that this latter substance may be an intermediate in the conversion of the testis hormone, testosterone, into the urinary androgen, androsterone. A. P. Lothrop

The factor curative of nutritional achromotrichia. Paul György, C. E. Poling and Yellapragada Subbarow. *J. Biol. Chem.* **132**, 789–90(1940); cf. *C. A.* **32**, 4201⁸.—

When concentrates of pantothenic acid with a degree of purification up to 40–50% are added to an achromotrichia-producing diet, the cutaneous lesions show distinct regression and the blackening of the fur also becomes definitely evident, the curative doses varying between 75 and 200 γ in terms of pantothenic acid. As a rule, however, the fur does not become completely black and depigmented areas often persist. It appears, therefore, that concentrates of pantothenic acid with a purification up to 40–50% contain 1 factor but not the only factor concerned in the cure of nutritional achromotrichia in rats. A. P. Lothrop

Experimental variation of the urea content of blood. E. B. Drevermann. *Med. J. Australia* 26, 747–51(1939).—Expts. on blood urea indicated that the urea content varied considerably with the diet. The ingestion of blood caused a significant rise in blood urea. The rise in blood urea after gastrointestinal hemorrhage is due in part to the urea formed by digestion of the blood proteins and due in part to the diminished excretion from a compensatory retention of fluid. G. H. W. Lucas

Malignant and nonmalignant uterine and vaginal lesions in mice receiving estrogens and estrogens and androgens simultaneously. W. U. Gardner and Edgar Allen. *Yale J. Biol. Med.* 12, 213–34(1939).—Subcutaneous injection of estrogens in variable amts in female mice from 8 strains resulted in 27 out of 249 showing epithelial lesions in the cervix or vaginal formix. Three of the lesions were carcinomas. Some mice would not tolerate the estrogen treatment for long periods. G. H. W. Lucas

Hibernation of the hedgehog. VI. Serum magnesium and calcium. Artificial hibernation. Chemical physiology of diurnal sleep. Paavo Suomalainen. *Ann. Acad. Sci. Fennicae* **A53**, No. 7, 68 pp.(1939); cf. *C. A.* **34**, 1067[2].—Though fasting for 7 days does not change serum Mg or Ca of the hedgehog, the former is 2.2 mg. % in summer waking state and 6.1 mg. % during midwinter hibernation, while the latter varies parallelly but to a lesser extent. In summer, Mg shows a marked diurnal rhythm, increased during sleep, but Ca does not vary distinctly. Blood sugar and adrenaline contents of adrenals are minimal in midwinter hibernation, but lowered in diurnal sleep. Injection of *M* $MgCl_2$ followed by subjection to low temp. produces anesthesia, low sensibility, low muscle tonus and poikilothermism, but blood sugar and adrenaline increase. *M* $MgCl_2$ and insulin (small dose) with cold, or insulin alone with cold, produces artificial hibernation with sensibility, muscle tone, blood sugar, adrenaline, serum Mg and Ca and body temp. as in normal hibernation. Transfer to room temp. produces awakening and normal values for the above variables. Adrenaline injection causing hyperglucemia does not influence serum Mg of the hedgehog. Normal men show diurnal increase in serum Mg in sleep. Diabetic patients show no abnormality in serum Mg and Ca and administered insulin does not cause consistent change. J. McAfee

The influence of the spleen on the formation of hematopoietic substance in the liver. Piero Foà. *Arch. fisiol.* **39**, 42–50(1939).—The liver of splenectomized animals contains less hematopoietic principle than that of normal animals. Theory: the spleen supplies the liver with some material necessary for the formation of the antianemic substance; this is probably derived from the blood destroyed in the spleen. A. E. Meyer

Gastric absorption, normal and under the influence of ortho- and parasympathicolytic substances. V. Martini, G. C. Morando and N. Minuto. *Arch. fisiol* **39**, 164–75(1939).—Solns. of glucose and sucrose (10–20%) introduced into the stomach are generally poorly absorbed. This is not influenced by the concn. The relative variations which occur are considerable. Atropine does not cause a definite change. Glycine is still less absorbed than glucose, frequently not at all. The injection of F 933 produces a 10-fold increase of absorption. A. E. M.

Pyruvic acid and methylglyoxal as intermediate products of the oxidative metabolism of carbohydrates. P. Foà and P. Fornaroli. *Arch. fisiol.* **39**, 210–17(1939).—After injection of lactic acid, its concn. in the blood increases to a max. and then decreases in a definite function of time, whereas pyruvic acid and glucose show considerable variations in their disappearance. Pyruvic acid disappears at a more rapid rate than lactic acid and simultaneously lactic acid and glucose increase. While lactic acid is formed from pyruvic acid, the reverse process does not occur. Methylglyoxal forms considerable quantities of glucose and lactic acid in the blood but pyruvic acid to only a minimal degree. A. E. Meyer

The action of the vagi on glucose metabolism. V. Zagami. *Arch. fisiol* **39**, 297–326(1939).—Pigeons show after vagotomy and in starvation a higher glycogen content in heart and liver but lower in the pectoral muscle, than nonoperated starved controls. The glucemia is increased by vagotomy. Insulin produces in both groups an increase in cardiac and a decrease in hepatic and muscle glycogen. The blood-sugar curve after insulin and adrenaline in both groups is identical. A. E. Meyer

The elimination of organic and inorganic phosphorus in muscle work. Piero Foà and Pietro Fornaroli. *Arch. fisiol.* **39**, 367–71(1939).—With increase of the intensity of work the elimination of inorg. P increases. The difference of P elimination between moderate and intense work is const. but not very striking. The org. P remains unchanged. A. E. Meyer

The antigonadotropic properties of serum from dogs treated with pituitary-like gonadotropic hormone. Francesco Guercio and Dino Cazzola. *Arch. fisiol.* **39**, 372–95 (1939).—Treatment with prolan causes in rabbits and dogs the appearance of antihormones. The potency can be maintained for an indefinite time with adequate treatment. Pos. complement deviation and precipitin tests were obtained in the rabbit. A quant. relation between the antihormonic and antigenic reactions could not be found. Antibodies were not found in the dog after 8 months' treatment. The ovaries in animals treated with prolan and antihormone serum simultaneously show complete neutralization. A. E. Meyer

The effect of ovariectomy and splenectomy on the antigonadotropic characteristics of rabbit serum. Francesco Guercio and Dino Cazzola. *Arch. fisiol.* **39**, 396–406 (1939).—Splenectomized rabbits did not develop antibodies against urinary gonadotropic hormones, and splenectomy after treatment caused the disappearance of the antibodies from the blood. The antihormonic effect, however, was not influenced by removal of the spleen. The identity of antihormones and antibodies is denied. Ovariectomy does not prevent the formation of antihormones. A. E. Meyer

The relation between antihormonic serum and zoölogical specificity. Francesco Guercio and Dino Cazzola. *Arch. fisiol.* **39**, 407–14(1939).—Three times the min. dose of pregnancy urine, sufficient to produce a pos. reaction in the virgin rabbit, was ineffective if 10 cc. of blood from a dog that had received treatment with urinary gonadotropic substance had been injected one hour before. A. E. Meyer

Current conceptions of the physiology of the kidney. J. M. Hayman, Jr. *Am. J. Clin Path.* **10**, 12–20(1940). John T. Myers

Renal function. M. Herbert Barker *Am J. Clin. Path.* **10**, 21–9(1940).—A review with 11 references. John T. Myers

Vitamins, hormones and yeast adenylic acid as induction substances in embryonal development. Paavo Suomalainen and Sulo Toivonen. *Ann. Acad. Sci. Fennicae* **A53**, No. 6, 20 pp.(1939).—The following substances were investigated: vitamins A, B_1 C, and D_2, riboflavin, adrenaline, thyroxine, heteroauxin and yeast adenylic acid. Induction did not take place in amphibian embryos with the vitamins. Adrenaline produced a conspicuous arching in the ectoderm. The most effective induction substance was yeast adenylic acid. H. J. Prebluda

Synthesis of ascorbic acid (vitamin C) in the egg of the hen during hatching. Paavo Suomalainen. *Ann. Acad. Sci. Fennicae* **A53**, No. 8, 13 pp.(1939); cf. *C. A.* **34**, 1455.—Ascorbic acid (I) is absent in the unhatched egg of the hen. During the first 2 weeks of incubation the total and reduced I increase; after this period there is an abrupt

decrease in both values. The total I is at its highest in the liver of chicks just emerged from the eggs, while the reduced I increases continuously for 4 days after the emergence. An aq. soln. of either glucose, mannose or sorbose when injected into the egg has no effect on the synthesis of I in the embryo. H. J. Prebluda

Temperature coefficients of enzymes in the course of development of the chicken embryo. E. V. Kolobkova. *Biokhimiya* 4, 295–302(1939).—Enzyme activity increases, and the temp. coeffs. decrease, as the embryo develops. H. Priestley

The working of muscles to exhaustion while a reserve of energetic substances is maintained. O. I. Falnshmidt. *Biokhimiya* 4, 411–22(1939).—No change occurs in the muscle content of energetic substances (creatine- and adenosinephosphoric acids, and glycogen) on the introduction of curare into rabbits. In curare-treated rabbits, the fatigued muscles fully maintain their reserve of energetic substances. The action of curare apparently depends on shutting off the motor innervation of the muscles, since the muscles of animals whose ischiadic nerves have been cut behave similarly. H. Priestley

Mechanism of ascorbic acid oxidation in animal tissues. B. I. Gol'dshtein and D. V. Vol'kenzon. *Biokhimiya* 4, 457-69(1939); cf. *C. A.* **33**, 1013[5].—Ascorbic acid is oxidized in Jensen rat sarcoma (but not in liver, kidney or spleen), during aeration and in the presence of pyrogallol and phenoloxidase. Addn. of H_2O_2 or peroxidase to the tissues of Jensen rat sarcoma and the spleen will cause the oxidation of ascorbic acid. The action will be still more intense if both H_2O_2 and peroxidase are added. Ascorbic acid in liver and kidney tissue is not oxidized by H_2O_2 and peroxidase H. Priestley

Regulation of respiration through phosphagen transformations. V. A. Belitser. *Biokhimiya* 4, 498–502(1939); cf. *C. A.* **33**, 6417[4], 6424[1].—Previously, it had been shown that decompn. of phosphagen leads to an increase in respiration; resynthesis, to a decrease. This is explained on the basis that the decompn. products of phosphagen are respiratory stimulants. The addn. of an aq. ext. of rabbit kidney or liver (which contains phosphagen decompn. products) markedly increases the respiratory effect of creatine H. Priestley

A biochemical study of cerebral tissue and of the changes in cerebral edema A. M. Stewart-Wallace. *Brain* **62**, 426–38(1939).—Cortical gray matter contained on the av. 84.3% H_2O as compared to 70.7% in the white matter of the cerebral hemispheres and to 70.6% in the white matter of the cerebellar hemispheres, while intermediate values were found for the thalamus (75.1%) and corpus callosum (75.5%). In the cells of the white and gray matter there were 7.8 and 6.9 milliequiv. of Na per 100 g. of cell water, resp., as compared to 2.5 in red cells and 0.29 in muscle cells. The amt. of K (11 3 and 11.2 milliequiv. % in white and gray matter, resp.) was approx. equal to the amt. in both red cells and muscle cells (11.4 and 12.4, resp.). P, expressed as percentage of dry weight, had values of 40.0 and 41.7 milliequiv. % in gray and white matter, resp. In local cerebral edema, some of which were assocd. with tumor of the brain, there was a large increase in the fluid content restricted to the white matter, of the centrum ovale which did not affect the cortex, thalamus, corpus callosum or internal capsule. Increases in H_2O, Na, Cl and K in the edematous tissue were in the same relative proportions as would be the case if the added fluid were a serum filtrate; this suggests that in cerebral edema there is an increase in interstitial fluid derived from circulating blood. The P content was slightly but consistently lower on the edematous side. Maurice M. Rath

Bromine content in human organism. J. Karp and Gerda Wolfsohn. *Schweiz. med. Wochschr.* **69**, 834–5 (1939).—In 66% of 40 normal subjects, the blood Br level varied between 600 and 800 γ. In the rest there were variations between 500 and 1033 γ. The Br content of cooking salt had no effect on the Br level of the blood. Subjects who lived in areas where the soil was rich in Br had normal blood values. Maurice M. Rath

The significance of unimolecular layers of fat acid in the control of animal oxidation. J. M. O'Connor. *Proc. Roy. Irish Acad.* **45B**, 355–71(1939).—The production of energy in animals is fairly const. Some member of the oxidizing system must respond to altered conditions to meet the change in the need for energy. Evidence has been adduced (*C. A.* **32**, 232[8]) to show that pH may play a role here. Studies using tissue exts. or sections have been made, but not with animals. In animals, as tissue is destroyed it is replaced and so a certain constancy of result may be expected. Frogs were placed in sealed vessels of accurately known vol., and O_2 consumption and CO_2 production were measured. These expts. were made at temps. of 4–30° on 150 animals. When O_2 consumption is plotted against t, a wide scattering of values is seen at 13–17°, and when log O_2 used is plotted against abs. temp. there is a discontinuity at 14°. At about 21° there is an increase, then at 30° the curve becomes linear again. With Langmuir's theory (*C. A.* **28**, 698[8]), it is suggested that the COOH groups of the fat acids on the catalyst hold the O_2 adsorbed, and the variation in the surface of the fat acid will det. the partial pressure of O_2. The sudden increase in O_2 used at about 15° is attributed to the melting of a unimol. layer of palmitic acid and the increase at 21° to the expansion of a unimol. layer of palmitic acid. The O_2 consumption is thus related to the change of fat acids from liquid condensed to liquid expanded states. In the frog, the increases in O_2 consumption seem to be proportional to the amt. of palmitic and myristic acids. M. S.

Vitamin B_1 in the animal organism. III. The maximum storage of vitamin B_1 in various species. P. C. Leong. *Biochem. J.* **33**, 1394–6(1939); cf. *C. A.* **31**, 4711[2].—The max. level of storage in the muscle and liver of the guinea pig, fowl and pigeon was studied. The highest concns. in the muscles of the guinea pig, fowl, pigeon and rat were 0.3, 0.3, 1.2 and 0.6 I. U. per g., resp. The corresponding values obtained for liver were 0.7, 0.7, 1.1 and 2.6. E. W. Scott

Metabolites of contracting muscle. Utilization of fumarate. Kenneth Harrison. *Biochem. J.* **33**, 1465–9 (1939).—A no. of fatty acids and α-monocrotonin (I) were supplied to frog sartorii stimulated 12 times a min. under completely aerobic conditions. Formic, oxalic, acrylic, crotonic, tiglic, sorbic, muconic, succinic, maleic and acetoacetic acids and I were not used in significant amts. during exercise. Fumaric acid disappeared at the rate of 8.6 mg./g. dry wt./hr.; a rough calcn. indicated that the amt. of fumarate consumed, if completely oxidized, would account for 94% of the total heat developed by the muscle. This rough calcn. is being checked by further expts. E. W. Scott

Vegetative nerves and the alveolar resorption of lung. I. The influence of nerve sections on the alveolar resorption. B. Resorption of particles. Kiyoshi Hurui. *J. Oriental Med.* **31**, 751–65(English abstr. 53)(1939); cf. *C. A.* **34**, 504[3].—The alveolar resorption of thorotrast (Heyden) is studied histologically as well as with röntgenograms with rabbits. The resorption is not affected by sympathectomy; but 5 days after vagotomy or 7 days after vago-sympathectomy, the resorption is greatly enhanced. S. Tashiro

The effect of anterior pituitary extracts on the insulin content of the pancreas. C. H. Best, James Campbell and R. E. Haist. *J. Physiol.* **97**, 200–6(1939); cf. *C. A.* **34**, 1059[8].—The subcutaneous injection of diabetogenic exts. of the anterior pituitary gland produces a prompt and extensive fall in the insulin content of dog pancreas. When, after 7 daily injections, the ext. is discontinued, a rise in insulin content is noted and the normal value is regained within 4 days. The rise and subsequent fall of the fasting blood-sugar values follow a curve the shape of which bears an interesting relationship to that which illustrates the decrease and recovery of the insulin content of pancreas. When permanent diabetes is established in dogs, the insulin content of the pancreas may vary from approx. 0.2 unit per g. to amts. too small to estimate. No evidence of recovery of the insulin content has been secured in animals in which permanent diabetes has been observed over long periods (up to 198 days). E. D. Walter

Fatty infiltration of the liver in pregnant ewes. L. C. Snook. *J. Physiol.* **97**, 238–49(1939).—Fatty infiltration of the liver is not a normal concomitant of pregnancy in the rat, rabbit, guinea pig or sheep. The fatty infiltration of the liver assocd. with ketosis in the pregnant ewe does not necessarily provoke harmful symptoms. In ketonemic, pregnant ewes the glycogen content of the liver is apparently reduced to negligible amts. Fatty infiltration of the liver was not assocd. with necrotic changes in the liver tissue. 2
E. D. Walter

Evocation in the chick. M. Abercrombie. *Nature* **144**, 1091–2(1939).—Evocation of neural tissue by chem. substances, including carcinogens, is possible in the chick embryo. Coagulated presumptive epidermis is also an evocator. The process of evocation in the chick is similar to that in the newt, but the degree of reactivity to individual chemicals is different from that of the newt.
E. D. Walter 3

Crystalline pressor substance (angiotonin) resulting from the reaction between renin and renin-activator. Irvine H. Page and O. M. Helmer. *J. Exptl. Med.* **71**, 29–42(1940).—Renin reacts with renin-activator to form a strong pressor substance which is heat-stable, H_2O- and EtOH-sol., fluorescent, acid-stable and alkali-labile. It is reducing and is destroyed by strong oxidizing substances. It forms cryst. salts with oxalic and picric acids. It is suggested that this be called *angiotonin* (I). I produces a sharp, immediate rise in arterial pressure when injected intravenously; pithing and dissipation of the anesthetic appear to increase the response; tachyphylaxis occurs, in contrast to renin, only after many single doses. The responses to adrenaline and I do not parallel one another; cocaine, atropine and stilbestrol do not affect the pressor action of I; suprarenalectomy in brief expts. is also without effect. Max. amts. of I result when the proportion 5 between renin and activator is roughly 3–100; this is not a stoichiometric relationship in the chem. sense. The temp. suitable for good yields is about 38° and the time of reaction 10–20 min. Renin destroys I when incubated with it. I causes marked contraction of intestinal segments of rabbits without reducing their rhythmic motion. It sensitizes the intestine to further doses of I and alters the intestine such that renin-activator contracts it. I also constricts the vessels of a rabbit ear perfused with blood or 6 Ringer soln. C. J. West

Experimental hypertension. X. The oxygen consumption of the ischemic kidney. C. Gerbi, B. B. Rubenstein and H. Goldblatt. *J. Exptl. Med.* **71**, 71–6(1940).—The consumption of O by slices of renal tissue of the rabbit was studied by means of the Warburg manometric method. The ischemic kidney of the rabbit shows a definite diminution of O consumption, compared with the normal kidney 7 (3.9 ± 1.4 for ischemic, 10.0 ± 2.2 S. C. for normal).

G—PATHOLOGY

Reactions resembling anaphylaxis ("tachyphylaxis") produced by sodium 2′-hydroxy-8′-acylaminonaphthalene-1′-azobenzene-2,5-disulfonate. H. E. Fierz-David, W. Jadassohn and E. Pfanner. *Helv. Chim. Acta* **22**, 1456–64 (1939)(in German); cf. *C. A.* **31**, 3148[2]; **32**, 4652[4], 5049[8], 5052[1]; **33**, 3876[7].—Compds. of Na 2′-hydroxy-8′-acylaminonaphthalene - 1′ - azobenzene - 2,5 - disulfonate with fat acids contg. more than 12 C atoms always induce *in vitro* intense, and for the most part neutralizable, contractions in the uterus of a guinea pig which has not been previously treated. Treatment with a member of this series following preliminary treatment with another 4 member of the same series frequently results in complete failure of the uterus to react. The corresponding compds. with fat acids contg. 12 or fewer C atoms never cause distinct contractions, but occasionally such compds. (C_{8-12}) produce neutralization. These substances, which induce contractions, do not effect an arrest of anaphylactic hypersensitivity and, conversely, reactions can be induced with these substances after previous induction of anaphylactic contractions of the muscle. The analogy between these reactions and the so-called "tachyphylaxis" is pointed out. The phenomenon is still unexplained.
Ruth Berggren

The physicochemical etiology of cancer (with special emphasis on the relation to solar irradiation). A. H. Roffo. *Strahlentherapie* **66**, 328–50(1939); cf. *C. A.* **26**, 1304, 5330; **27**, 2997; **28**, 3125[3]; **29**, 507[2], 5871[4,5], 5886[8]; **30**, 126[3], 2494[9], 4521[8]; **31**, 1828[5], 4347[8], 4713[2], 6082[8]; **33**, 1030[9], 2901[8], 5417[7], 8209[3], 8277[6]. Ruth Berggren

Phosphatase activity in chronic arthritis. Charles Leroy Steinberg and Louise Catherine Suter. *Arch. Internal Med.* **64**, 483–92(1939).—Serum phosphatase detns. were made in 62 patients with various types of arthritis and in 6 healthy persons. Normal values were found in chronic atrophic and hypertrophic arthritis. Abnormal values suggest the possibility of complicating conditions or an erroneous diagnosis. J. B. Brown

Blood guanidine. Further observations. Ralph H. Major, C. J. Weber and M. J. Rumold. *Arch. Internal Med.* **64**, 988–93(1939); cf. *C. A.* **33**, 5480[6].—The compd. previously designated "guanidine" is a guanidine deriv., possibly glycocyamidine. In exptl. renal insufficiency, both with and without accompanying hypertension, there is an increase in "guanidine." J. B. B.

Multiple myeloma. Helmuth Ulrich. *Arch. Internal Med.* **64**, 994–1016(1939).—A review of the literature and clinical findings in a case of multiple myeloma are included in this study. Blood protein was high (over 10% serum protein); blood calcium high with normal or high serum P; Bence-Jones protein was present in urine. J. B. Brown

Lipocaic and fatty infiltration of the liver in pancreatic diabetes. Lester R. Dragstedt, Cornelius Vermeulen, W. Carter Goodpasture, Paul B. Donovan and Wm. A. Geer. *Arch. Internal Med.* **64**, 1017–38(1939).—The depancreatized dog is not restored to normal by the adequate administration of insulin and pancreatic juice. The deficiency is corrected by feeding pancreas and certain exts. of pancreas but not exts. of other organs. These facts demonstrate that lipocaic is an internal secretion of the pancreas. Two types of fatty infiltration of the liver develop in diabetes mellitus and in pancreatic diabetes: one is due to poor control of the diabetes by in-

sulin which is followed by normal or high blood lipides with acidosis, and the other is due to lipocaic deficiency accompanied by low blood lipides, impaired hepatic function, decreased dextrose excretion and insulin sensitivity. Ninety-two % of 154 depancreatized dogs developed fatty infiltration of the liver. A lipocaic assay method is described. Liver fat analyses by histological examn. and chem. procedures are compared. Two g. of choline per day are required to relieve fatty infiltration in depancreatized dogs. High-fat, low-protein diets accelerate and low-fat, high-protein diets delay appearance of fatty livers. A fat-free alc. ext. of pancreas is described, contg. only a few mg. of choline, which contains an adequate curative dose of lipocaic. Lipocaic is insol. in 90% alc. so that the hormone is probably removed from insulin during its purification. J. B. Brown

Elevation of urea nitrogen content of the blood following hematemesis or melena. Leon Schiff, Richard J. Stevens and Ellen S. Garver. *Arch. Internal Med.* **64**, 1239–51(1939).—The urea N of the blood is frequently elevated in hematemesis and melena, the degree of rise being of definite prognostic significance. In single hemorrhage with recovery the rise is max. in 24 hrs. with a sharp drop to normal by the 3rd day. Where there is a 2nd nonfatal hemorrhage, there may be secondary rise in 24 hrs. In repeated bleeding there is persistent high blood urea N. J. B. Brown

Physiologic basis of intravenous dextrose therapy for diseases of the liver. Samuel Soskin and Mayer Hyman. *Arch. Internal Med.* **64**, 1265–70(1939).—Mostly a review. J. B. Brown

The pathology of chloride metabolism in man. Alexander Lyall. *Brit. Med. J.* **1939, II**, 760–4.—This is largely a review of the importance of Cl metabolism in intestinal obstruction, pyloric stenosis, chronic nephritis, edema, obesity hypertension and Addison's disease, including some original observations by L. J. B. B.

Clinical porphyrinuria with a report of a case of the idiopathic type. F. G. Chandler, G. A. Harrison and C. Rimington. *Brit. Med. J.* **1939, II**, 1173–80.—The chemistry of the porphyrins is reviewed. "The urine may contain uroporphyrin or coproporphyrin or both and 2 isomers of each (I and III) have to be considered; methods for the sepn. and identification of these are described; in our case of acute idiopathic porphyrinuria, uroporphyrin III accounted for about 99% of the total urinary porphyrins." J. B. Brown

A secretory depressant in the achlorhydric gastric juice of patients with carcinoma of the stomach. Alexander Brunschwig, T. Howard Clarke, John Van Prohaska and Robert L. Schmitz. *Surg. Gynec. Obstet.* **70**, 25–30 (1940).—The achlorhydric gastric juices of 21 out of 27 patients with gastric carcinoma were found to contain a substance which inhibits gastric secretion. The inhibitant is inactivated by boiling for 10 min. J. B. B.

Chemical changes in the blood and their clinical significance. V. C. Myers and E. Muntwyler. *Physiol. Rev.* 20, 1–37(1940).—The review article considers blood vol., hemoglobin, serum proteins, nonprotein N, urea N, uric acid, creatinine, guanidines, sugar, fat, phospholipides, cholesterol, bilirubin, carotene, acid-base balance, Na, K, Ca, Mg, Cl, P, phosphatase and S. 228 references. H. R. Getz

Immunity in invertebrates. C. G. Huff. *Physiol. Rev.* 20, 68–89(1940).—A review article which discusses natural, acquired, cellular, humoral immunity, and hypersensitivity, questioning specificity of acquired immunity. When antibodies already exist, the response to vaccination is more marked. Bacteriolysins of invertebrates are thermostable; this indicates that the antibodies differ from those of vertebrates. Complement has not been found, but complementary action does occur. 191 references. H. R. Getz

The functional significance of specific agglutinins and precipitins. Paul R. Cannon. *Physiol. Rev.* **20**, 89–115(1940).—The article is a review pointing out the need of greater emphasis on the early effects of agglomerating antibodies in tissues. Agglutinins may combine with their resp. antigens in blood or tissues, promoting adherence of microörganisms to one another and tissues. Precipitins react similarly in blood or tissues causing an accelerated removal or prompt localization of antigen near the portal of entry. The evidence strengthens the view that agglomerating reactions act to immobilize and destroy foreign proteins entering parenterally. Toxicological by-products may constitute actual disease, also exaggerated antigenic stimuli may cause cellular injury or death. Pathol. effects all follow cellular stimuli. Therefore, it seems logical to blame the stimulus rather than the cell, recognizing that biol. processes may be harmful at times, but in fundamental aspects be protective. 131 references. H. R. Getz

Precipitin antiserums for malignant tissue. Lawrence S. Mann and Wm. H. Welker. *Proc. Soc. Exptl. Biol. Med.* **43**, 18–19(1940).—Preliminary. Specific antiserums (rabbit) were prepd. for the proteins of various malignant tissues (human and rat). L. E. Gilson

Effect of specific kidney antiserums on the normal kidney. Alexander M. Buchholz. *Proc. Soc. Exptl. Biol. Med.* **43**, 20–2(1940).—In dogs the injection of potent dog kidney antiserum (rabbit) produced within one hr. a drop in blood pressure, appearance of protein, red blood cells and granular casts in the urine, and the microscopic pathol. changes of extreme diffuse vascular dilatation, increase of Bowman's space, branching of glomeruli, tubular degeneration and leucocytic infiltration of the entire kidney. L. E. Gilson

Preparation and diagnostic value of an antiserum for placental protein. Harold R. Cohen and Vincent C. Freda. *Proc. Soc. Exptl. Biol. Med.* **43**, 22–3(1940). L. E. Gilson

Peptone shock in fetal dogs and its significance in the metabolism of histamine. Carl A. Dragstedt, Max Ramirez de Arellano and Alfred H. Lawton. *Proc. Soc. Exptl. Biol. Med.* **43**, 28–9(1940); cf. *C. A.* **33**, 4308[1].—The liver of a 200-g. dog fetus contained 5 mg. of histamine per kg. The skeletal muscles contained very little, perhaps none. Peptone shock can be produced in the dog fetus and is assocd. with the liberation of histamine as in the adult dog. L. E. Gilson

Isolation of antibody from agglutinate of type I pneumococcus by treatment with acid. Kwan-Hua Lee and Hisen Wu. *Proc. Soc. Exptl. Biol. Med.* **43**, 65–9(1940); cf. *C. A.* **33**, 8283[7].—By treating the agglutinate of type I pneumococcus (pptd. by immune rabbit serum) with dil. HCl at pH 2 all the antibody is liberated, and after removing the cells and neutralizing as much as 87% can be recovered in a form at least 95% pure. The vaccine can be used repeatedly for the isolation of the antibody. L. E. Gilson

Metabolic changes in diphtheria and influence of adrenal cortical hormone and vitamin C. J. Dieckhoff. *Deut. med. Wochschr.* **65**, 1418–21(1939).—The decrease in the respiratory metabolic rate of rabbits which follows the injection of diphtheria toxin can be prevented by the administration of adrenal cortical extract and ascorbic acid. The use of these substances is therefore advocated in treating diphtheria. Arthur Grollman

The water and salt exchange of the body under normal and pathological conditions. E. Kirk. *Deut. med. Wochschr.* **65**, 1741–5(1939).—A discussion of some clinical conditions in which there is a disturbance of the salt and H_2O metabolism. Arthur Grollman

The carcinogenic action of phenanthrene derivatives obtained from cholesterol. A. H. Roffo. *Z. Krebsforsch.* **49**, 341–7(1939).—See *C. A.* **33**, 8277[6]. Harriet F. Holmes

The carcinogenic action of benzopyrene in the rabbit. O. Schürch. *Z. Krebsforsch.* **49**, 353–62(1939).—Cancers can be produced by painting the ears of rabbits with benzopyrene as well as with tar. The latent period is a long one, and from 3 paintings a week with a 0.5% benzopyrene soln., cancers appear on an av. after 2 yrs. and 3 months. As compared with tar painting benzopyrene painting shows more tendency to produce follicular hyperkeratoses, keratinized precancerous warts, epithelial horns

and carcinomas with marked keratinization. One malig- 1
nant metastasizing melanoma was obtained and 2 very large fibromatous tumors markedly rich in collagen fibrils. One of these fibromatous tumors disappeared after the injection of estroglandol, but the other fibromatous tumor and the benzopyrene carcinomas were not affected by estroglandol injection. Harriet F. Holmes

The presence of *d*(−)-glutaminic acid in tumor proteins. I. C. Dittmar. *Z. Krebsforsch.* **49**, 397–8(1939).—By 2
the method of Kögl (*C. A.* **33**, 5060[6]) glutaminic acid was isolated as chlorohydrate from the proteins of Jensen sarcoma, Rous sarcoma and chicken muscle. The prepns. all gave the normal optical rotation of *l*(+)-glutaminic acid and had the same m. p., while Kögl from the lowering of the m. p. and diminished optical rotation concluded that up to 40% of the *d* (−) form of glutaminic acid was present in tumorous tissue. It is to be noted, however, that Kögl was working solely with carcinomas, 3
and it is probable that the changes in the proteins that he described apply only to epithelial tumors. II. *Ibid.* 441–2.—Further work on the isolation of glutaminic acid from tumor proteins indicates the presence of *d*(−)-glutaminic acid as shown by alterations of m. p. and optical rotation in benzopyrene mouse sarcoma, mouse sarcoma 179, mouse chondroma 72, and mouse carcinoma (5 Fischer). However, the presence of *d*(−)-glutaminic acid does not seem to be specific for tumor proteins, for 4
material free from necrosis from Jensen and Rous sarcomas gives no *d*(−)-glutaminic acid, while necrotic material from Jensen sarcoma shows a change in m. p. and optical rotation indicating the presence of *d*(−)-glutaminic acid. The glutaminic acid from the relatively fresh tissue of the benzopyrene sarcoma shows only a slight amt. of the *d*(−)-form. The appearance of *d*(−)-glutaminic acid seems to depend not on the malignant change 5
of the cells but on their necrotic disintegration.
H. F. H.

The preparation of an antigenic toxin from Salmonella enteritidis. Fred L. Humoller, A. C. Lonert and Clement G. Bottino. *J. Infectious Diseases* **65**, 206–13 (1939).—A method for the isolation of an antigenic endotoxin from *S. enteritidis* organisms grown on liquid medium is described and consists essentially of concn., dialysis and pptn. with alc. The same substance was apparently ob- 6
tained from organisms grown on broth, broth diffusate and on synthetic medium, but it could not be obtained from sterile culture fluids. The toxic fraction obtained when injected repeatedly in sublethal amts. into mice induced a slight but, nevertheless, definite immunity against lethal doses of the toxin and the living *S. enteritidis* organisms. When injected in minute amts. into rabbits the toxin produced hyperglucemia and leucopenia. The 7
chem. and biol. properties of the toxic fraction appear to be very similar to those of certain fractions obtained by previous workers from related organisms grown on solid mediums. Julian H. Lewis

The specificity of proteolytic enzymes from tumors. Joseph S. Fruton, Geo. W. Irving, Jr., and Max Bergmann. *J. Biol. Chem.* **132**, 465–6(1940); cf. *C. A.* **33**, 9340[4].—The proteolytic enzymes in exts. of breast carcinoma and bone sarcoma split *l*-leucinamide either not at all or rather 8
slowly. Bashford mouse carcinoma ext. hydrolyzed *l*- and *d*-leucinamide at similar rates. All the tumor exts. hydrolyzed carbobenzoxy-*l*-glutamyl-*l*-tyrosine. The breast and Bashford carcinomas acted also on carbobenzoxy-*d*-glutamyl-*l*-tyrosine which contains the unnatural *d*-glutamic acid. Enzyme solns. from carcinomas are much less stable than those of other tissue exts. and also show a marked autodigestion at pH 4–5 in the presence of cysteine.
A. P. Lothrop 9

A comparison of the optical forms of glutamic acid from normal and cancerous tissue. J. M. Johnson. *J. Biol. Chem.* **132**, 781–2(1940).—Jensen rat sarcoma was hydrolyzed with 20% HCl and the normal livers of rats bearing this tumor and also livers from normal rats were used for comparison. *l*(+)-Glutamic acid was the principal constituent of the glutamic acid fraction from normal and tumorous liver tissue but a small amt. of *d*(−)-glutamic acid was apparently also present in the hydrolyzate of normal as well as tumorous tissue. These findings suggest the possibility of a slight racemization during hydrolysis of the protein. Cf. Kögl and Erxleben, *C. A.* **33**, 7376[4].
A. P. Lothrop

Chemical studies on the nature of susceptibility to spontaneous carcinoma of the mammary gland in mice. Leonell C. Strong. *Yale J. Biol. Med.* **12**, 255–67(1940).—A study of the action of the antioxidant salicylaldehyde (dil. in olive oil) has shown that male mice of 3 distinct strains differ significantly in their tolerance to this substance. The max. degree of tolerance was reached when the hemoglobin level was at its peak and then declined with advancing age. The suggestion is made that the oxidation-reduction phenomena within the body are part of the susceptibility to carcinoma mechanism.
G. H. W. Lucas

Utilization of lactic acid, pyruvic acid and methylglyoxal in the diabetic organism. P. Foà and P. Fornaroli. *Arch. fisiol.* **39**, 218–28(1939).—Lactic acid and methylglyoxal cannot be used directly by the depancreatized dog. It seems that pyruvic acid is used directly in the diabetic organism as concluded from its rapid disappearance after injection and the simultaneous decrease of sugar in blood and urine. Lactic acid and methylglyoxal are probably not normal products of carbohydrate metabolism as is pyruvic acid. Na pyruvate is recommended for the treatment of diabetic acidosis. A. E. Meyer

Serological diagnosis of malignant tumors: the determination of the iodine value as a method of diagnosis of neoplastic affections. Giuseppe Oliva and Giovanni Fassone. *Arch. sci. med.* **68**, 477–504(1939).—Dry 1 cc. of serum on filter paper or on kaolin and ext. for 8 hrs. with 25 cc. Et_2O; wash 2 times with 10 cc. Et_2O. Evap. to dryness and take up the residue with 10 cc. of a mixt. of equal parts of 0.01 *N* I in 96% EtOH and 0.6% $HgCl_2$ in EtOH. After 8 hrs. add 50 cc. H_2O, 2 cc. 10% KI soln. and 3 drops of starch soln. and titrate with 0.01 *N* $Na_2S_2O_3$. Titrate a blank and express values in cc of difference of both titrations. Normal persons (12) showed values from 0.19 to 0.43, av. 0.27; patients with malignancies (26) 0.72 2.93, av. 1.33; patients with benign tumors 0.35 to 0.74, av. 0.58; patients with hepatic disease without jaundice 0.25–0.44, av. 0.35, and with jaundice av. 1.09; with kidney disease 1.02–1.45. Patients with a large no. of other ailments were investigated also. A. E. Meyer

Glucemic and carotinemic curves after insulin and adrenaline in normal and diabetic persons. Giuseppe Oliva and Marco Pescarmona. *Arch. sci. med.* **68**, 537–46 (1939).—The blood carotene is not influenced by either adrenaline or insulin. The high carotene content found in the blood of diabetic patients is an indirect consequence of metabolic disturbances connected with the disease.
A. E. Meyer

Crystalline horse hemoglobin as an antigen. Wm. C. Boyd and Saul Malkiel. *J. Bact.* **39**, 32(1940).—Injection into rabbits of cryst. horse hemoglobin together with killed microörganisms (*Monilia*) enhances the antigenic strength of the organism. John T. Myers

Quantitative studies with antiserums to pneumococcus carbohydrate-anticarbohydrate precipitates from horse and rabbit antiserums. Henry P. Treffers and Michael Heidelberger. *J. Bact.* **39**, 35–6(1940).—Certain water-sol. antibodies (from anti-type I, type II, and C pneumococcus horse serums) are identical antigenically, but a water-sol. antibody (horse anti-egg albumin) represents a different protein. The groupings responsible for the antibody function constitute either a small part of the total protein mol. or else fail to influence antigenic behavior for other reasons. John T. Myers

"Incomplete" or "univalent" antibody, a common constituent of antiserums. Michael Heidelberger and Manfred Mayer. *J. Bact.* **39**, 37(1940).—Fractional exhaustion with homologous antigen usually leaves a significant portion of antibody in soln. even in the presence of excess antigen. This form of antibody seems to be "univalent" or else it contains too few immunologically reactive groupings to build up the large insol. aggregates

presumably formed by the union of multivalent antigen with multivalent antibody. John T. Myers

Normal tobacco plant protein and tobacco mosaic virus protein as anaphylactogens and precipitinogens in the guinea pig. Helen Purdy Beale and Beatrice Carrier Seegal. *J. Bact.* **39**, 38–9(1940).—Normal tobacco protein was a relatively poor anaphylactogen while the tobacco mosaic protein was good. Hence this will not serve as a test for normal tobacco protein in the presence of mosaic virus protein. John T. Myers

Combined artificial fever and chemotherapy in dementia paralytica. A. E. Bennett, J. C. Nielsen, A. H. Fechner and Paul T. Cash. *Arch. Phys. Therapy* 20, 620–7(1939).—Clinical remissions in paretic dementia were about 20% greater after a full course of combined artificial fever and tryparsamide therapy than from malarial inoculation. The percentage of serological reversal was also higher after combined therapy and the percentage of full clinical remissions in early paresis was better than 60%. Maurice M. Rath

Blood changes in dystrophia and myotonia. J. N. Cummings and O. Maas. *Brain* **62**, 422–5(1939).—There was no significant difference in the serum K levels in 2 normal subjects, 2 patients with myasthenia gravis and in 2 patients with loss of muscular power, before and after exercise. Patients with myotonia but no wasting of muscles showed definite fall in serum K after exercise. Myotonic patients with wasting showed no alteration in the K level after exercise. It is highly probable that the lowering of the serum K after exercise is accompanied by an increase in muscle K. Based on this assumption, the greater ability to use affected muscles after mild exercise is either due to, or is accompanied by a, more normal level of K in muscle. Maurice M. Rath

Congenital myotonia in the goat. G. L. Brown and A. M. Harvey. *Brain* **62**, 341–63(1939).—Myotonic muscles were abnormally sensitive to K ions. A dose of KCl which had no effect in normal muscle produced a contraction of considerable tension in the myotonic muscle. Although approx. the same doses of acetylcholine were required to produce an equiv. tension max. in the myotonic as in the normal muscle, a given dose of acetylcholine produced in the former a response of much greater duration. Curarization of the muscle did not modify the characteristic responses of the myotonic muscle to mech. stimulation nor did it have any effect on the response of these muscles to KCl. Eserine in a dose of 200 γ produced at least a 50% potentiation of the nerve twitch tension when injected arterially into the tibialis group of a normal goat and had the same effect on the myotonic goat. 21 references. Maurice M. Rath

Elimination of volatile phenols in the urine of patients with pernicious anemia. M. Volterra. *Schweiz. med. Wochschr.* **69**, 627–9(1939).—The excretion of volatile phenols in these patients was slight but increased after treatment with liver prepns. Maurice M. Rath

The mechanism of diabetic disturbance using the "nitrogen minimum excretion" as a measure of gluconeogenesis. S. J. Thannhauser. *Endocrinology* **26**, 189–200 (1940).—A method is described for studying gluconeogenesis and N min. excretion (I) on patients with diabetes on a N min. diet. I was normal in 4 cases of moderate diabetes even with temporary omission of insulin. It was slightly increased in 3 cases of severe diabetes. With the omission of insulin I of these patients increased and simultaneously large amts. of sugar, 4–7 times higher than the amt. expected from the increased figures of I, appeared in the urine. Insulin does not act directly on gluconeogenesis but acts on intermediate sugar disintegration. Irradiation of the pituitary caused only a slight temporary depression of I. Injection of exts. of total pituitary and adrenal cortex had no influence on I of patients with moderately severe diabetes. Felix Saunders

Amebic dysentery. XXIII. Chemotropic reaction of dysenteric amebas to bacteria, bacterial toxins and other substances. Y. Matuura. *J. Oriental Med.* **31**, 611–64 (English abstr. 45–6)(1939).—Unlike polymorphonuclear leucocytes, dysenteric amebas (A) are not attracted by pathol. and nonpathol. bacteria or by bacterial toxins. A and polymorphonuclear leucocytes are not mutually chemotropic. Leucocytic infiltration in the amebic lesions must be caused by the secondary bacterial infection but not by A. A is chemotropic to its own ext. and mildly attracted to the blood of human subjects, rabbits, guinea pigs and cats, but not to that of horses. The reaction to other substances, such as kaolin and paraffin, is also studied. **XXIV. Chemotropic reaction of dysenteric amebas to the organs of dogs, rabbits and cats.** *Ibid.* 665–714(English abstr. 47).—A does not show any signs of chemotropism to the normal tissues of lung, liver, spleen, kidney, brain, muscle, thyroid gland, pancreas, adrenal gland, testicle and ovary of rabbits, cats and dogs. **XXV. Galvanotropism of dysenteric amebas.** *Ibid.* 715–19(English abstr. 48).—Like non-pathogenic amebas, A too shows negative (cathodic) galvanotropism. Cf. *C. A.* **32**, 5058[9]. S. Tashiro

Chemical studies on bacterial agglutination. V. Agglutinin and precipitin content of antiserums to Hemophilus influenzae, type B. Hattie E. Alexander and Michael Heidelberger. *J. Exptl. Med.* **71**, 1–11(1940); cf. *C. A.* **32**, 3815[6].—The quant., abs. methods of agglutinin and precipitin analysis previously developed for antipneumococcus serums have been shown to be applicable to horse and rabbit anti-influenza type B serums and plasma. With the aid of these methods and improved immunization schedules the antibody content of the rabbit serums was increased 5–10 times. The method recommended for the purification of rabbit antipneumococcus antibody was also applicable to rabbit anti-influenza type B serums. C. J. West

Electrophoretic study of nephrotic serums and urine. L. G. Longsworth and D. A. MacInnes. *J. Exptl. Med.* **71**, 77–82(1940).—The electrophoretic patterns of the serums and urine of 2 cases of lipoid nephrosis were obtained and compared with a typical pattern of normal serum. The patterns of the pathol. serums deviated widely from the normal; this indicated relatively low albumin and high globulin content. The comparison of the patterns of nephrotic serums cleared by centrifugation and by Et_2O extn. showed that a large portion of the β-globulin consisted of a labile lipoprotein. The pattern of the nephrotic urine proteins resembled that of normal serum with, however, significant differences. C. J. West

Sensitization of animals with simple chemical compounds. VII. Skin sensitization by intraperitoneal injections. K. Landsteiner and M. W. Chase. *J. Exptl. Med.* **71**, 237–45(1940); cf. *C. A.* **33**, 5489[4].—A method is described by which sensitization to 2,4,6-$(O_2N)_3C_6H_3Cl$ can be satisfactorily attained by means of intraperitoneal injection of the compd. when killed tubercle bacilli suspended in paraffin oil were used as adjuvant. Sensitivity of the contact dermatitis type results therefrom. It follows that, although skin sensitization of this type is most easily obtained by dermal application, this route of administration is no necessary condition for such sensitivity. C. J. West

Molecular weight of diphtheria toxin, antitoxin and their reaction products. A. M. Pappenheimer, H. P. Lundgren and J. W. Williams. *J. Exptl. Med.* **71**, 247–62(1940).—Purified diphtheria antitoxic horse pseudoglobulin (I) has been prepd. which is homogeneous by sedimentation, diffusion and electrophoresis. Immunologically, however, the prepn. contains only 43.5% antitoxin specifically precipitable by toxin. The inactive I remaining after sp. pptn. was found to have the same phys. and chem. properties as the original active I. Although the mol. wt. of antitoxin is the same as that of normal horse serum globulins, the electrophoretic mobility does differ from those normally present. The mol. wt. of diphtheria toxin is 70,000 and of antitoxin 150,000. From ultracentrifuge studies on the 2 reactants and on mixts. of toxin and antitoxin in the sol. inhibition zones, the av. mol. compn. of the sp. floccules at certain reference points throughout the equivalence zone and the max. "valence" of toxin and antitoxin with respect to each other have been calcd. The significance of the results are discussed in

relation to antigen-antibody reactions in general and a possible explanation for the exceptional behavior of the toxin-antitoxin reaction in the region of excess antitoxin is suggested. C. J. West

Quantitative theory of the precipitin reaction. VII. The egg albumin-antibody reaction in antisera from the rabbit and horse. Michael Heidelberger, Henry P. Treffers and Manfred Mayer. *J. Exptl. Med.* **71**, 271–82 (1940); cf. *C. A.* **31**, 7111[1].—In 2 rabbits subjected to prolonged injections with cryst. egg albumin the antibodies in one showed progressive changes such as those noted previously; the antibodies in the other did not. The significance of this behavior in the production of sera for therapeutic use is pointed out. Quant. studies are reported on the low-grade or incomplete antibody present in the early stages of immunization of a horse with egg albumin and on the flocculating antibody from later bleedings from the horse and the dissocn. of the sol. prezone compds. by rabbit anti-egg albumin is studied. Rough velocity estns. are reported. The bearing of the findings on the mechanism of precipitin and flocculation reactions and of the Danysz effect (*C. A.* **31**, 5863[7]; **33**, 8782[2]) is discussed in terms of the union of multivalent antigen with multivalent antibody. C. J. West

Immunological studies of pollinosis. I. The presence of two antibodies related to the same pollen-antigen in the serum of treated hay-fever patients. Mary Hewitt Loveless. *J. Immunol.* **38**, 25–50(1940).—The skin-sensitizing naturally occurring antibody (atopic reagin) was characterized by thermolability—2–5 hrs. at 56° destroyed it. A thermostable antibody produced in normal individuals and also in pollen-sensitive persons by injections of pollen-antigen was not destroyed when kept at 56° for 24 hrs. Numerous serological properties of the 2 kinds of antibody are described. Charles A. Zittle

CARL F. SCHMIDT

The effect of prontosil on avian malaria: a preliminary report. Candido M. Africa, Francisco J. Dy and Lily J. Soriano. *Acta Med. Philippina* **1**, 19–29(1939).—Intramuscular injections of prontosil into "maya costa" (*Padda oryzivora* Linnaeus) exptly. infected with *Plasmodium praecox* resulted in complete disappearance of the parasites. Ruth Berggren

Influence of certain drugs and anesthetics upon gastrointestinal tone and motility. J. Dewey Bisgard and E. K. Johnson. *Ann. Surg.* **110**, 802–22(1939).—Drugs commonly employed in the pre- and postoperative care of patients have either strong motor or strong inhibitory influences upon the tone and peristaltic activity of the gastrointestinal tract. The influence an individual anesthetic has upon the gastrointestinal tract may be dependent upon its influence upon the relative quantities of O in the blood or tissues during anesthesia. When inhaled, O stimulates and CO_2 inhibits gastrointestinal motor activity. Rachel Brown

The hyperglucemic action of snake venoms. Gabriel Bertrand and Radu Vladesco. *Compt. rend.* **209**, 818–21 (1939); cf. *C. A.* **34**, 1395[5].—A substance with hyperglucemic action was found in varying amts. in all of 14 venoms examd. It should not be confused with echidnase or with echidnovaccin. Rachel Brown

Methylene blue as an antidote for poisoning by oat hay and other plants containing nitrates. W. B. Bradley, H. F. Eppson and O. A. Beath. *J. Am. Vet. Med. Assoc.* **96**, 41–2(1940); cf. *C. A.* **33**, 4693[6].—Two g. of methylene blue is sufficient to protect cattle weighing up to 250 kg. against the ingestion of 6.3 kg. of plant material contg. 5% of KNO_3. Rachel Brown

Treatment with sulfanilamide of meningo-encephalitis associated with canine distemper. M. L. Morris and T. J. Murray. *J. Am. Vet. Med. Assoc.* **96**, 80–6(1940).—Of 30 dogs affected with meningo-encephalitis and treated with sulfanilamide 93% recovered. The blood-sulfanilamide level was maintained at not less than 15 mg. %. Rachel Brown

The control of the blood flow through the intestine as studied by the effect of adrenaline. Robert H. Goetz. *Quart. J. Exptl. Physiol.* **29**, 321–31(1939); cf. *C. A.* **33**, 9439[6].—The effect of adrenaline (I) upon the intestinal blood vessels depends upon the dose. The smallest doses produce only increase in intestinal vol.; after larger doses a feeble and transient early decrease takes place followed by a prolonged dilatation. No relation could be detected between the effect of I on the intestinal vessels and the course of the blood pressure response. The results support the view that I acts as a blood-distributor and not blood pressure-augmentor hormone. Rachel Brown

The clearance of sodium evipan. S. C. Das and J. Raventós. *Quart. J. Exptl. Physiol.* **29**, 343–54(1939).—The effects produced on the respiratory activity of the rabbit by continuous intravenous injection of Na evipan (I) can be explained on the assumption that about $1/_{25}$ of the amt. present in the body is inactivated every min. The relations between dosage and duration of respiratory depression in the rabbit indicate a clearance of about $1/_{22}$ per min. The effects of continuous intravenous injection in mice and monkeys indicate, resp., rates of clearance of $1/_{35}$ and $1/_{80}$ per min., while the dosage-duration of narcosis relation indicates rates of $1/_{110}$ and $1/_{140}$ per min. Rachel Brown

Antagonism of evipan by picrotoxin, coramine and cardiazole. S. C. Das. *Quart. J. Exptl. Physiol.* **29**, 355–65 (1939).—The production of a steady state of respiratory depression by continuous intravenous infusion of Na evipan (I) into rabbits affords a convenient method for measuring the efficiency of analeptic drugs and for comparing their relative activities. Picrotoxin (II) causes an increase in the depth of respiratory movement as well as in the rate, whereas coramine (III) and cardiazole (IV) improve the rate of respiration rather than the depth. Three-tenths mg. of II causes the same increase in amplitude of respiratory stimulation as 10 mg. of III or of IV. II takes 3–5 min. to develop its max. effect while III or IV reaches its max. very quickly. When the respiratory depression is severe III often fails to produce a stimulant effect and may even augment the depression. II produces a stimulant effect in such cases. II is detoxified at the rate of $1/_{10}$ and IV at the rate of $1/_{16}$. There is a linear relation between the doses of I and the log of the doses of II which balance each other. Continuous infusion of III superimposed on the continuous infusion of I at first shows an increase in respiratory activity and then a fall and a final depression which may be greater than that produced by I alone. Rachel Brown

Action of morphine and its derivatives, especially dihydrohydroxycodeinone, on the sensitivity to acetylcholine of leech muscle treated or not with eserine. P. Dodel, G. Dastugue and A. Bresson. *Compt. rend. soc. biol.* **132**, 267–8(1939).—The denervated noneserinized leech muscle was sensitized to acetylcholine by dil. solns. of heroine (1:1000); dionine, thebaine and papaverine (1:5000); apomorphine (1:10,000); morphine and codeine (1:400,000); and by dihydrohydroxycodeinone in dilns. approaching that commonly used for eserine (1 in several millions). If the muscle was first treated with eserine dil. solns. of all the above compds. antagonized the action of acetylcholine to some extent. L. E. Gilson

Two new substituted vinyl barbituric acids. James P. Hendrix. *J. Pharmacol.* **68**, 22–35(1940).—5-Ethyl- and 5-propyl-5-(1-methyl-1-butenyl)barbituric acids are potent narcotics showing a wide margin of safety in rats and

dogs. **The Et compd. has been tried in human subjects with satisfactory results.** The action was relatively brief. Both compds. were less depressant to blood pressure upon intravenous injection in dogs than was isoamylethylbarbituric acid, and, like the last-named, decreased the O utilization of white rats. L. E. Gilson 1

The effect of intravenous injections of sodium diphenylhydantoinate (dilantin) on respiration, blood pressure and the vagus nerve. Victor G. Haury and Miles E. Drake. *J. Pharmacol.* **68**, 36–40(1940).—Na diphenylhydantoinate when injected intravenously in dogs or rabbits produces an immediate 30–65% fall in blood pressure. This action is peripheral. The compd. has a depressant action on the vagus nerve and has a marked depressant action on respiration. Lethal doses produce death by respiratory failure. L. E. Gilson 2

Use of pentamethylenetetrazole (metrazole) as a respiratory stimulant in acute alcoholic depression. F. D. McCrea and Haywood M. Taylor. *J. Pharmacol.* **68**, 41–4(1940).—Dogs given 3–5 cc. abs. EtOH per kg. intravenously went into a coma from which they were partially aroused for periods of 30–45 min. by injection of moderate doses of metrazole, after which they again became comatose. If they were given 7 cc. EtOH per kg even large doses of metrazole did not arouse them. Recovery from coma began 3–12 hrs. after injection of the alc., depending on the amt. injected. The metrazole had no effect on the duration of the coma or on the rate of disappearance of the alc. from the blood stream. L. E. Gilson 3

Effect of age of cats on susceptibility to digitalis. H. B. Haag and R. L. Corbell, Jr. *J. Pharmacol.* **68**, 45–9 (1940).—The lethal doses of 2 tinctures of digitalis, one specimen of amorphous gitalin and 2 samples of ouabain were detd. for kittens 5–10 weeks old and for adult cats. No difference in tolerance was found for the different age levels. Therefore children should not be given digitalis in doses proportionately larger than those recommended for adults. L. E. Gilson 4

The passage of bromide, iodide and thiocyanate into and out of the cerebrospinal fluid. G. B. Wallace, B. B. Brodie, Seymour Leshin and Elliott Brand. *J. Pharmacol.* **68**, 50–5(1940); cf. *C. A.* **33**, 2986[9].—When the salts are injected intravenously into dogs the anions begin to pass promptly into the spinal fluid, but, their passage into the spinal fluid, unlike the case of other tissue fluids, is slower and never reaches the concn. present in the blood serum. Furthermore the serum must attain a certain min. concn. of iodide or thiocyanate ion before any passes into the spinal fluid. The bromide ion may also have a threshold value, but if so it is very low. When injected into the spinal cistern all 3 of the ions pass quickly into the blood at the same rate and there is no evidence of any barrier to their passage. L. E. Gilson 5 6 7

Some pharmacological properties of unsymmetrical ethyl-*o*-ethylphenylurea. Axel M. Hjort, Edwin J. De Beer, Johannes S. Buck and David W. Fassett. *J. Pharmacol.* **68**, 56–61(1940).—Unsym. ethyl-*o*-ethylphenylurea, m. 71°, prepd. by reacting *o*-EtC_6H_4NHEt with nitrourea, is sol. in water to the extent of 0.0185 g. per g. satd. soln. at 25°. It is more sol. in water, equally effective as a hypnotic, and less toxic than its isomer propyl-*o*-tolylurea. Its median hypnotic dose for mice, rats and dogs lies between 50 and 70 mg./kg. It lowers body temp. and depresses blood pressure. In chronic and acute toxicity studies in rats it produces no pathol. changes in the vital organs. **Hypnotic effect of repeated injections of unsymmetrical ethyl-*o*-ethylphenylurea in albino rats and the influence of sex thereon.** A. M. Hjort, E. J. De Beer and D. W. Fassett. *Ibid.* 62–8.—The effect was greater in females than in males. L. E. Gilson 8 9

Some tetrahydroisoquinolines. A note on the relative lethal and circulatory effects of some 2-alkyl derivatives. Axel M. Hjort, Edwin J. De Beer and David W. Fassett. *J. Pharmacol.* **68**, 69–72(1940); cf. *C. A.* **33**, 4320[8] and following abstr.—In a series of 2-alkyl-1,2,3,4-tetrahydroisoquinoline homologs the toxicity increased with lengthening of the alkyl chain (from Me to Am) in the normal homologs, but not to the degree found with homologous ureas. The isohomologs (iso-Pr, iso-Bu and iso-Am) showed no consistent trend with lengthening of the chain. All the compds. had a depressor action. L. E. Gilson 10

Tetrahydroisoquinolines. IV. Circulatory and adrenolytic effects. Axel M. Hjort, Edwin J. De Beer and David W. Fassett. *J. Pharmacol.* **68**, 73–9(1940); cf. *C. A.* **33**, 4320[8] and preceding abstr.—The action of 25 substituted 1,2,3,4-tetrahydroisoquinolines was studied. Most of those with secondary and tertiary amine N produced adrenaline vasomotor reversal in dogs. In general the tertiary amines were more effective than the secondary. The methoxy derivs. were more active than the ethoxy. The 2-alkyl, but otherwise unsubstituted, derivs. were the most potent of the isoquinoline adrenolytic agents so far studied. The more active ones compare favorably with ergotoxin, F 883, F 933 and yohimbine in antagonizing adrenaline. L. E. Gilson 11 12

Further observations on the effect of parenteral injection of certain methylated purines on creatine-creatinine metabolism. A. Link Koven and Howard H. Beard. *J. Pharmacol.* **68**, 80–4(1940); cf. *C. A.* **32**, 7126[1].—In young rats injections of theophylline and aminophylline produced increases in muscle creatine somewhat smaller than those produced by comparable doses of caffeine and theobromine. Urinary excretion of creatine was increased. Increases in the creatine of the liver, kidneys and heart, and in creatinine excretion, did not occur. L. E. G. 13 14

Cyclopropane studies. VIII. Effect of premedication with morphine or amytal on the heart rate, rhythm and blood pressure in dogs under cyclopropane anesthesia. Benjamin H. Robbins and James H. Baxter, Jr. *J. Pharmacol.* **68**, 85–95(1940); cf. *C. A.* **33**, 5914[7].—In nonpremedicated dogs cyclopropane increased the heart rate and blood pressure, but cardiac irregularities were rarely observed before the respiration was greatly depressed. After morphine premedication cyclopropane decreased the heart rate and blood pressure, and cardiac irregularities were always produced but could be abolished by 1–2.5 mg./kg. of amytal given intravenously. After amytal premedication cyclopropane produced no cardiac irregularity and no significant change in heart rate and blood pressure. L. E. Gilson 15 16

Some new aspects of morphine action; effect on intestine and blood pressure; toxicity studies. Donald Slaughter and E. G. Gross. *J. Pharmacol.* **68**, 96–103 (1940).—Eserine enhances the action of morphine on the intestine by making small ineffective doses effective. Eserine enhances the action of morphine in lowering the blood pressure of the cat. Toxicity studies on white rats indicate an enhancing effect of these drugs since $^1/_2$ the m. l. d. of each when given together kills more animals than the m. l. d. of either when given alone. It is believed that morphine acts through a cholinergic mechanism to produce these results. **New aspects of morphine action; effects on pain.** Donald Slaughter and Donald W. Munsell. *Ibid.* 104–12.—Morphine effect is enhanced by prostigmine when pressure-pain responses in cats are detd. Atropine counteracts the effect of morphine or of morphine and prostigmine together. In many ways morphine acts like a cholinergic drug. The mechanism of such action is discussed. L. E. Gilson 17 18

Cardiovascular changes following the intravenous administration of barium chloride. Paul K. Smith, Alexander W. Winkler and Hebbel E. Hoff. *J. Pharmacol.* **68**, 113–22(1940).—$BaCl_2$ was injected into dogs with ligated ureters at a slow uniform rate until death occurred. The effects on the heart were irregular. Numerous electrocardiograms and arterial blood pressure records are shown. L. E. Gilson 19

Toxicity of lasiocarpine. K. K. Chen, Paul N. Harris and Hans A. Schulze. *J. Pharmacol.* **68**, 123–9(1940).—Lasiocarpine is an alkaloid from *Heliotropium lasiocarpum*, family Borraginaceae. The intravenous injection of 50–100 mg./kg. in rats and mice causes death, usually after several days delay. The principal lesion is necrosis of the liver. Cloudy swelling of the kidneys also occurs. In dogs repeated daily doses of 10–20 mg./kg. produce no 20

injury. The drug has a depressor action in anesthetized cats. It does not affect the blood sugar of rabbits when injected in sublethal doses. L. E. Gilson

Action and toxicity of platyphylline and seneciphylline. K. K. Chen, Paul N. Harris and Charles L. Rose. *J. Pharmacol.* **68**, 130–40(1940).—At least 17 different alkaloids have been found in different species of *Senecio*. Platyphylline (I) and seneciphylline (II) occur in *S. platyphyllus*. Intravenous injection of II in mice, rats and guinea pigs produces tonic convulsions. Death may be immediate or may be delayed several days in which case it is due to necrosis of the liver. Cloudy swelling of the kidneys is also produced. Lethal and near-lethal doses of I produce convulsions in all exptl. animals but there is no delayed death and no damage to liver or kidneys. I also has an atropine-like action. L. E. Gilson

Prevention of the blood pressure fall during procaine spinal anesthesia in the rabbit. Elizabeth M. Cranston and Raymond N. Bieter. *J. Pharmacol.* **68**, 141–9(1940). —Drugs or drug combinations found effective were: synephrine, synephrine plus pitressin, ephedrine plus pitressin plus metrazole, ephedrine plus pitressin, neosynephrine plus pitressin, and neosynephrine plus pitressin plus metrazole. L. E. Gilson

Effect of sympathomimetic and other substances on the contraction of skeletal muscle. Edith Bülbring and J. H. Burn. *J. Pharmacol.* **68**, 150–72(1940).—When skeletal muscle, perfused with defibrinated blood, is stimulated at a rapid rate so that fatigue is produced, adrenaline augments the height of the contraction although it reduces the blood flow. This augmentation is largely but not entirely due to improvement of transmission of nerve impulses. A similar augmentation is produced by ephedrine, tyramine, synephrine and dihydroxyphenylethylamine, but much higher concns. are required and the action is more prolonged. Cocaine acts in the same way and possibly this action is the basis of its power to increase phys. endurance. Ergotoxine and posterior hypophysis ext. also augment the muscle contraction. The effect appears to be produced by all vasoconstrictor substances. L. E. Gilson

Studies on the mechanism of the protective action of xanthine against carbon tetrachloride poisoning. J. C. Forbes and E. L. Outhouse. *J. Pharmacol.* **68**, 185–93 (1940); cf. *C. A.* **33**, 3884[5].—The subcutaneous injection into rats of substances known to exert a protective action against CCl_4 or $CHCl_3$, such as xanthine, India ink, $Ca_3(PO_4)_2$ and Na ricinoleate, always causes a marked drop in serum esterase concn. Control rats poisoned with CCl_4 show a marked rise in serum esterase while those protected with xanthine do not. Feeding a high-fat diet increases susceptibility to CCl_4 and $CHCl_3$ and also causes a marked rise in serum esterase. The rise in serum esterase does not bear any definite relation to the lipide content of the liver. Serum esterase decreases markedly during the period of rapid liver repair following acute CCl_4 poisoning. L. E. Gilson

Comparative effects of propylene glycol, other glycols and alcohol on the liver directly. H. W. Newman, W. Van Winkle, Jr., N. K. Kennedy and M. C. Morton. *J. Pharmacol.* **68**, 194–200(1940); cf. *C. A.* **33**, 9395[6], 9441[8].—Propylene glycol decreased the O consumption and CO_2 output of the isolated cat liver perfused with cat blood, but increased the glycogen of the liver and the lactic acid of the blood and decreased the utilization of glucose by the liver. Addn. of insulin to the perfusion with propylene glycol caused a further decrease in the O consumption, prevented the increase in blood lactic acid and increased the utilization of the glycol. Ethylene, diethylene and dipropylene glycols were not utilized by the perfused liver, but depressed O consumption and increased lactic acid production. The dipropylene glycol was the least toxic of the 3. EtOH was metabolized by the perfused liver, but depressed its functional activity as indicated by decrease in O consumption, increase in lactic acid formed, and decrease in glycogen. L. E. Gilson

An experimental comparison of sulfanilamide and benzylsulfanilamide with particular reference to the significance of variations in experimental technique. John S. Lockwood and Harry J. Robinson. *J. Pharmacol.* **68**, 201–15(1940); cf. *C. A.* **33**, 7368.—Benzylsulfanilamide was slightly less effective than sulfanilamide in treating exptl. streptococcic peritonitis in mice. Exptl. methods are discussed. L. E. Gilson

Interpretation of diodrast clearances in the dog. H. L. White and Peter Heinbecker. *Proc. Soc. Exptl. Biol. Med.* **43**, 8–10(1940). **Interpretation of diodrast clearances in man.** H. L. White, Thomas Findley, Jr., and Joseph C. Edwards. *Ibid.* 11–14. L. E. Gilson

Serum albumin regeneration following intravenous injection of amino acids (hydrolyzed casein) in hypoproteinemia produced by severe hemorrhage. Robert Elman and Harriet Wolf. *Proc. Soc. Exptl. Biol. Med.* **43**, 14–16 (1940); cf. *C. A.* **33**, 5453[4].—Enzyme-digested casein was used. Only 70% of the N was amino acid N; the rest probably was present as dipeptide. Its intravenous injection into a bled dog was followed in a few hrs. by a significant increase in serum albumin. Since the serum globulin concn. and the relative red cell vol. both decreased it is inferred that serum albumin was regenerated. L. E. Gilson

Vitamin C and mushroom poisoning. G. Holland and W. Chlosta. *Deut. med. Wochschr.* **65**, 1852–4(1939).—The administration of ascorbic acid to a patient suffering from mushroom poisoning prevented the occurrence of petechial hemorrhages. In poisoned guinea pigs the administration of ascorbic acid also prevented hemorrhages in the internal organs but did not prevent the death of the animals. Arthur Grollman

Action of *p*-aminobenzylsulfamide and carboxysulfamidochrysoidine in experimental diphtheria intoxication. Bruno Bartolini and Alessandro Bocca. *Boll. soc. ital. biol. sper.* **14**, 603–4(1939).—The sulfamide prepns. exerted no prophylactic action in exptl. diphtheria intoxication. Helen Lee Gruehl

Action of barium and magnesium on contractile activity of the chick-embryo heart. Rita Rondinini. *Boll. soc. ital. biol. sper.* **14**, 605–7(1939).—$MgCl_2$ and $BaCl_2$ exerted the same action as did $CaCl_2$ and KCl. H. L. Gruehl

Pharmacological studies on phenylisopropylamine. V. Action on isolated rabbit intestines. A. Chistoni and E. Beccari. *Boll. soc. ital. biol. sper.* **14**, 612–14(1939); cf. *C. A.* **33**, 6958[7].—In concns. less than 1:10,000 phenylisopropylamine acted like ephedrine and in greater concns. it acted like adrenaline. Helen Lee Gruehl

Influence of the portal of entry (subcutaneous or peritoneal) on the degree of toxicity of some poisons. G. Battelli. *Boll. soc. ital. biol. sper.* **14**, 642–4(1939).—Apomorphine was more toxic when injected subcutaneously; atropine and Na barbital were more toxic when injected intraperitoneally. The basis for these results is discussed. Helen Lee Gruehl

Cerebral action of camphor, sodium santonate and cocaine with simultaneous administration of β-phenylisopropylamine. G. Rizzotti and F. Sivieri. *Boll. soc. ital. biol. sper.* **14**, 664–7(1939).—The assocn. of β-phenylisopropylamine with any of the above substances prolonged and aggravated the symptoms and caused convulsions in doses which individually had no such effect. H. L. G.

Immediate rigor mortis from 2,4-dinitrophenol. S. Cerquiglini. *Boll. soc. ital. biol. sper.* **14**, 672–4(1939). Helen Lee Gruehl

Effect of the antidiabetogenic duodenal factor on the antiinsulin action of the glucotropic principle of the anterior lobe of the hypophysis. A. De Barbieri. *Boll. soc. ital. biol. sper.* **14**, 674–6(1939).—The glucotropic principle completely inactivated the hypoglucemizing action of insulin in rabbits. Previous oral administration of the antidiabetogenic factor apparently inactivated the glucotropic principle. Helen Lee Gruehl

Action of insulin and the antidiabetogenic duodenal factor on experimental ketosis. A. De Barbieri and D. Puzzuoli. *Boll. soc. ital. biol. sper.* **14**, 676–8(1939).—Both substances produced a marked diminution in ketosis caused by the ingestion of Na acetoacetate. H. L. G.

Action of adrenal cortex extract on nitrogen metabolism. F. Addarii and F. Scarlini. *Boll. soc. ital. biol. sper.* **14**,

691–2(1939).—Adrenal cortex ext. increased N elimination but the percentage increase was lower than that of the diuresis. Helen Lee Gruehl

Relation between the pancreas and sodium chloride. F. Addarii. *Boll. soc. ital. biol. sper.* **14**, 692–4(1939).—Injections of insulin into depancreatized dogs caused an elevation of the sugar, Na and Cl titers of the blood to normal values and a secondary lowering of the acetone and N. Urinary Na and Cl rapidly diminished after a transient slight increase of Na excretion. Helen Lee Gruehl

Relation between the vitamin content and the hypoglucemizing action of Rosa canina. Luigi Callegari. *Boll. soc. ital. biol. sper.* **14**, 698–9(1939).—Vitamins B_1 and C were apparently not the substances responsible for the hypoglucemizing action of the ext. of *Rosa canina*. Helen Lee Gruehl

Comparative studies of the octyl series. Renzo Agnoli. *Boll. soc. ital. biol. sper.* **14**, 702–3(1939).—Octyl bromide, secondary octylamine, dioctylamine and trioctylamine caused varying degrees of hypotension in the rabbit. Octyl sulfocyanide, primary octylamine and diethyloctylamine gave indefinite results. Diethylamine-HCl caused hypertension. Octyl ether produced initial hypotension and return to normal pressure with subsequent persistent hypotension for several minutes. Helen Lee Gruehl

Pharmacological action of Cupressus sempervirens. Alberto Garello Cantoni. *Boll. soc. ital. biol. sper.* **14**, 703–5(1939).—Expts. on the smooth muscle of the intestinal roundworm (*Ascaris lumbricoides*) showed that an infusion of the buds of the cypress had no vermifuge properties. The essential oil distd. from the leaves was effective only in large doses. Helen Lee Gruehl

Pharmacological action and the association of Verbascum thapsiforme with Urtica dioica L. Alberto Garello Cantoni. *Boll. soc. ital. biol. sper.* **14**, 705–8(1939).—Infusions of both plants were tested on frog heart. The assocn. caused no change in the actions of the drugs. H. L. G.

Absorption of iodine after percutaneous and intestinal administration of salt waters containing bromine and iodine. Mario Cavazzini. *Boll. soc. ital. biol. sper.* **14**, 716–17(1939).—Absorption of I through the skin and intestines of rabbits was demonstrated by the presence of I in the urine. Helen Lee Gruehl

Modifications of the phosphorus/nitrogen and calcium/nitrogen ratios in the bones of young rats after prolonged administration of sodium bromide. B. Tanzi. *Boll. soc. ital. biol. sper.* **14**, 728–30(1939).—Four litters of rats were treated with NaBr and the femur and tibia analyzed. In general, the water content, N, P and Ca titers diminished to varying degrees. The P/N and Ca/N ratios diminished in some instances and increased in others. Helen Lee Gruehl

Phosphorus/nitrogen and calcium/nitrogen ratios in the osseus tissue of rats during hematoporphyrinized growth. B. Tanzi. *Boll. soc. ital. biol. sper.* **14**, 730–2(1939).—In general, the P/N and Ca/N ratios of the femur and tibia of rats treated with hematoporphyrin-HCl diminished. The degree of diminution varied in the 2 bones under different conditions of light and dark and with various com. prepns. Helen Lee Gruehl

Pharmacological action on the uterine muscle of a new alkaloid (basergine) from ergot compared with that of a posthypophysis derivative (orasthine). Tullio Meneghini. *Boll. soc. ital. biol. sper.* **14**, 735–6(1939).—Both substances were active only in concns. above 1:40,000 but the type of contraction varied. Basergine could exert a reversible action in weak concns. while orasthine did not. The combined action of the 2 drugs varied according to which was added first. Helen Lee Gruehl

Hypoglucemizing and antidiabetic action of citric acid. L. Cannavò and G. Ortoleva. *Boll. soc. ital. biol. sper.* **14**, 740–1(1939).—Oral administration of 5 to 8 g. citric acid or Na citrate lowered blood sugar of persons with diabetes or other forms of hyperglucemia and had little effect on normal persons. Helen Lee Gruehl

The action of mixtures of quinine and pituitary (posterior lobe) extract on the uterus of the virgin guinea pig. H. A. Shapiro. *S. African J. Med. Sci.*, Feb., Suppl. to Vol. **4**, 9–12(1939).—A com. sample of pituitary (posterior lobe) ext., having a strength of 10 international units/cc., was used in this investigation. The biol. assays were performed on the isolated virgin guinea-pig (approx. 250 g.) uterus suspended in a bath the temp. of which was maintained at 37°. Nine biol. assays of quinine-HCl solns. were made against corresponding dilns. of the com. sample of known wt. made with glass-distd. water. In addn. 5 assays with the dihydrochloride of quinine as diluent were made. Consistent results were obtained in all expts. An addn. of quinine, whether in the form of the mono- or the dihydrochloride, to pituitary ext. lessened very considerably the action of the hormone as tested on the virgin guinea-pig uterus. The expts. with the dihydrochloride suggest that quinine may exert a paralyzing action on the uterine muscle of the virgin guinea pig, a point which is being investigated further. The results obtained may not be directly applicable to man, as the action of mixts. of quinine and pituitary ext. may be different on human uterus. If similar conditions are present in the human uterus the 2 substances should be given separately if their full effects are to be obtained. Two references are given. W. R. Henn

The present state of the chemotherapy of gonorrhea. R. A. Rubi. *Rev. med. cienc. afines* **1**, 18–27(1939). E. H.

Arsenical encephalopathy. I. Clinical study. A. Tzanck and S. Lewi. *Ann. dermatol. syphilig.* **10**, 752–70 (1939).—Arsenical encephalopathy is produced by trivalent arsenicals of the arsenobenzene type and by quinquevalent arsenicals derived from 3-amino-4-hydroxybenzenearsonic acid, e. g., stovarsol, treparsol, acetylarsan. It is never produced by mineral arsenicals (arsenic anhydride, arseniates, cacodylates, etc.) nor by quinquevalent org. arsenicals derived from p-aminobenzenearsonic acid, e. g., atoxyl or tryparsamide, despite the fact that these compds. may exert toxic action on the peripheral nervous system. Intravenous, intramuscular, subcutaneous, oral and vaginal administration of arsenicals have all led to encephalopathy. According to Budlowsky (*Deut. derm. Ges. in der Tschech. Rep.* (Dec. 3, 1933)) patients with encephalopathy give neg. skin tests to arsenicals. However, Kapuscincki (*Ceska Dermatol. Samberger Festschr.* **148**(1931)) claims to have induced passive sensitization to neoarsphenamine by injection of serum from a patient showing intolerance to this drug. Five cases are presented of encephalopathy due to neoarsphenamine; two of the patients were pregnant women, who seem, as a group, to be especially susceptible to this disorder. Marion Horn

The effect of eserine on spinal reflexes in the dog. Jerome K. Merlis and Hampden Lawson. *J. Neurophysiol.* **2**, 566–72(1939).—Eserine (physostigmine salicylate), given intravenously in doses of 0.01–2.0 mg./kg. in 5 cc. Ringer's soln., proved predominantly depressant to the knee-jerk and augmentory to the flexion (tibialis anticus) and crossed extension (quadriceps) reflexes of the chloralosed or barbitalized dog. Similar effects were obtained when the drug, in 0.025–0.2% concn. in Ringer's soln., was applied to the spinal cord by perfusion through the lumbar subarachnoid space in the intact or spinal dog. Various theories of the mode of action of eserine are discussed. Marion Horn

Brain potential changes in man during cyclopropane anesthesia. Morton A. Rubin and Harry Freeman. *J. Neurophysiol.* **3**, 36–42(1940).—There are 6 discrete changes in the frequency of brain potentials in man during cyclopropane anesthesia and recovery from it. The changes are too abrupt to be explained by a postulated decrease in metabolism of neurons, and may be caused partially by a decrease in cell permeability during anesthesia, which in turn influences the ionic relationship between the cells and their environment. In addn., a blocking of afferent impulses, known to occur during anesthesia, may bring cortical neurons to various levels of excitation at which synchronization can occur. Although there is not as great individuality of potential patterns during anesthesia as in the waking state, it is nevertheless pos-

sible to differentiate between anesthetized individuals on the basis of their encephalograms. In the few instances in which the patient was allowed to rebreathe his own CO_2 early in anesthesia to prevent respiratory failure this always hastened the onset of deep anesthesia and made the slow rhythms characteristic of this stage much more regular than usual. Marion Horn

Ocular rotation in anesthesia and under the influence of supranuclear centers. Ernest A. Spiegel and Dean A. Collins. *J. Neurophysiol.* **3**, 59–65(1940).—Ocular rotation in cats was produced to a marked extent by the brain-stem anesthetics Na pentobarbital, Na phenobarbital, Na barbital, dial-urethan and urethan. Only a slight degree of ocular rotation was produced by the cortex anesthetics ether, chloroform and Gréhaut's mixt. (5% chloroform in 50% alc.). However, another so-called cortex anesthetic, chloralose, produced marked ocular rotation. Marion Horn

Some experiments on chemotherapy of sulfanilamide for gonorrhea. Zaii Sai. *Japan. J. Exptl. Med.* **17**, 387–406(1939)(in English).—The concn. of sulfanilamide which completely inhibits the bacterial growth in general corresponds to the amt. present in the blood of patients who are being treated with 2–5 g. of the drug per day. By comparison of exptl. data of results with blood inactivated by heating at 58° for 30 min. and fresh blood S. is able to show that there is a certain factor in fresh blood which coöperates with sulfanilamide in the killing of the gonococcus. C. Jarowski

The effect of alcohol upon the chemotactic response of leucocytes. R. S. Klepser and W. J. Nungester. *J. Infectious Diseases* **65**, 196–9(1939).—Polymorphonuclear cells of deeply intoxicated rats lost their pos. chemotaxis toward pneumococci. The white cells of human blood to which alc. had been added showed the same failure to be attracted to pneumococci. The av. distance traversed by each cell in a given period of time was less in the alc. blood, and more cells were nonmotile than in the normal group. Rats chronically intoxicated are more susceptible to pneumococcus infections than control animals. J. H. L.

The therapeutic properties of sulfanilamide in experimental pneumococcal infections. L. H. Schmidt and Carolyn Hilles. *J. Infectious Diseases* **65**, 273–84(1939); cf. *C. A.* **33**, 7892[3].—Sulfanilamide had marked therapeutic properties when administered to mice infected intraperitoneally with types I to XXXII pneumococci. Administration of 10 mg. of sulfanilamide as frequently as every 6 hrs. was necessary for obtaining max. therapeutic response. Such treatment maintained a concn. of 8–12 mg. % free sulfanilamide in the blood. When mice were treated this intensively, the initial therapy could be delayed for 6–12 hrs. after pneumococci had invaded the blood without complete loss of the beneficial effects of therapy. With some groups of pneumococci sulfanilamide had a high degree of curative action, with others it had less curative action but marked life-prolonging properties, and with still others the drug had no curative action but did prolong life. Julian H. Lewis

Effects of neoarsphenamine and sulfarsphenamine on experimental fuso-spirochetal infection in guinea pigs. Theodor Rosebury, Genevieve Foley and Fred L. Rights. *J. Infectious Diseases* **65**, 291–300(1939).—The results of expts. on the effect of neoarsphenamine and sulfarsphenamine on exptl. fuso-spirochetal infections of guinea pigs are in accord with clinical and other data in indicating that topical application of these drugs is a rational form of therapy in accessible fuso-spirochetal infections of man, but do not support the practice of intravenous or intramuscular administration of arsenicals in treatment of these diseases. Julian H. Lewis

Carbohydrate metabolism in ether anesthesia. I. Fate of injected *d*-lactic acid in the dog, the rabbit and the rat. N. M. Phatak. *Anesthesia and Analgesia* **19**, 18–26 (1940).—A slower rate of disappearance of *d*-lactate from the blood of dogs and rabbits was obtained than ever published previously for this or *dl*-lactate. It was not excreted in significant amts. in urine and was well utilized in dogs, rabbits and rats. Whereas during anesthesia ether interfered with the proper utilization of this *d*-lactate, it furnished a ready store for replenishing depleted stores of liver glycogen and counteracted the severe acidosis of ether anesthesia. G. H. W. Lucas

The effect of certain barbiturates on the response to vasoactive substances. Richard Kohn-Richards and Clyde Grimes. *Anesthesia and Analgesia* **19**, 31–4(1940). A study of the influence of several barbiturates on blood-pressure changes produced by acetylcholine in decapitated cats showed that some, like pentothal, increased the depressant action of the acetylcholine and others, like evipal, counteracted the drug. These drugs did not change the typical effect of histamine. The vasopressor responses to pituitrin were increased 15–20% by both pentothal and nembutal. G. H. W. Lucas

Intracaine; its application to spinal anesthesia. R. S. Sappenfield and E. A. Rovenstine. *Anesthesia and Analgesia* **19**, 48–52(1940).—Intracaine, closely related to procaine (the amino group in the para position on the benzene nucleus of procaine is replaced by an alkoxy radical), was studied in about 100 cases for spinal anesthesia. A 2.5% soln. was found satisfactory. Doses of 25–75 mg. produced sensory anesthesia for 45–60 min. When doses of 100 mg. or over were given, anesthesia was shorter than that expected from similar amts. of procaine. It did not exhibit any special advantages. G. H. W. Lucas

An antidiabetogenic effect of a primary alcoholic extract of pituitary tissue administered orally. J. B. Collip. *Can. Med. Assoc. J.* **42**, 109–13(1940).—A preliminary report on the study of the effects of oral administration of a primary alc. ext. of prime pituitary tissue to diabetic patients, normal persons, depancreatized and normal monkeys, rabbits and rats showed that the ext. exerted considerable influence on carbohydrate metabolism. It had no effect in the absence of the pancreas. G. H. W. Lucas

The toxicity changes of various arsenobenzene preparations through oxidation; the increased toxicity of the substances formed when the above solutions were exposed to air. III. The toxicity of the oxidation product of these preparations for mice and the physicochemical properties of these products. Koeki Kondo. *Folia Pharmacol. Japon.* **27**, 324–48(Breviaria 59–60)(1939); cf. *C. A.* **34**, 819[9].—The toxicity of neo- and myo-arsenobenzene to mice always increased when the solns. were exposed to air for some time. The latter changed more rapidly than the former. All solns. changed color on standing and finally a ppt. formed. Neoarsenobenzene changed the most rapidly and myoarsenobenzene the most slowly. Increased temp. hurried this reaction. The pH decreased and viscosity increased as the solns. changed to a wine-red. G. H. W. Lucas

Diethylaminoethylephedrine (isalon) in comparison with ephedrine with respect to its effect on respiration, bronchial muscles and their spasms, as well as to its toxicity. Hirosi Matumoto. *Folia Pharmacol. Japon.* **27**, 349–64 (Breviaria 60–1)(1939); cf. *C. A.* **33**, 8807[6].—Ephedrine in moderate dosage increased respiration in rabbits a little more than did isalon; in large doses both arrested it. Both drugs produced relaxation in the bronchial musculature of the ox and relaxed bronchial muscle in the rabbit which had been thrown into a spasm by acetylcholine or histamine. The action of ephedrine was more pronounced than that of isalon, but was weaker than that of adrenaline. Isalon was somewhat more toxic than ephedrine to mice when injected subcutaneously or intravenously. G. H. W. Lucas

Cellular reactions to lipoid fractions of the tubercle bacillus. Robert M. Thomas. *Yale J. Biol. Med.* **12**, 283–6(1940).—Phthiocerol, an alc. deriv. from human and bovine tubercle bacilli, when placed in the abdominal tissue of rabbits did not produce a granulation of tissue resembling that appearing in an active tuberculous process. G. H. W. Lucas

Studies on the cancerogenic azo and related compounds. Riojun Kinosita. *Yale J. Biol. Med.* **12**, 287–300(1940). —Some 50 azo and related compds. were tested for their potency in producing hepatic cancer in rats. Butter Yellow was the most potent and growths induced showed a very

high malignancy in histological structure, growth, metastasis, etc. G. H. W. Lucas

The influence of liver extract on the oxygen consumption of mammalian erythrocytes. I. Properties of the constituents of the system. G. A. Overbeek. *Rec. trav. chim.* **58**, 1018–32(1939); cf. Michaelis and Salomon, *C. A.* **24**, 5356; Damblé, *C. A.* **27**, 2204; Deutsch and Wagenfeldt, *Deut. Arch. klin. Med.* **171**, 73(1931).—Centrifuged Ringer soln. ext. of blood-free liver, like methylene blue, augments erythrocyte respiration. Both factors can be made limiting by increasing the concn. of the other components. Rabbit and human cells are most affected by liver ext., hog poorly, rat not always. This order parallels the magnitude of blood catalase index, though the effect is not related to catalase level. Glucolysis may be involved since NaF favors the effect. Rat and rabbit cells respond alike to methylene blue. Augmentation by liver ext. is observed in cells from pernicious anemia patients, and in concd. hemolyzates. The latter are not affected by methylene blue. Boiled or ultraviolet-irradiated liver exts. and antianemic liver prepns. are inactive. Rat livers yield more active exts. than rabbit livers. Addn. of substrate (glucose, lactate but not pyruvate) is necessary for liver ext. effects and the R. Q. is 0.9. II. **Influence of cyanide and narcotics.** *Ibid.* 1033–9.—Very small quantities (6.25 γ/ml.) of KCN inhibit liver ext. augmentation, larger (200 γ/ml.) the methylene effect. At KCN concns. not inhibiting, variation in methylene blue concn. does not change the result; perhaps this is explained by the dual nature of the respiration (cf. *C. A.* **26**, 1326). Phenylurethan and ethylurethan have almost no inhibitory effect on erythrocyte or hemolyzate respiratory augmentation by liver ext. Anaerobic Thunberg detn. indicates absence of dehydrogenases insensitive to narcotics. Methylene blue augmentation is inhibited by urethans. J. McA.

The cardiac action of nicotine and its interpretation with reference to the humoral transmission of nerve impulses. I. The action on the myocardium. V. Gronchi. *Arch. fisiol.* **39**, 51–68(1939).—Nicotine has a triphasic action on the myocardium inhibition (I), excitation (II) and a 3rd phase characterized by regular rhythm with increased inotropism and decreased chronotropism. On repeated administration of nicotine the first phase disappears. As in the heart it produces in the isolated skeletal muscle first an increase, later a progressive decrease, of elec. excitability. II. *Ibid.* 69–87.—Phases I and II are not caused by excitation and paralysis of the ganglia by a direct and simultaneous stimulation of the cholinergic and adrenergic nerve endings with preponderance of the vagal effect in phase I and the sympathetic in phase II. Phase III corresponds with a paralysis of both nerve endings combined with a direct and reversible action on the muscle. This latter fact is proved by the decreasing responsiveness of the myocardium to adrenaline, acetylcholine and faradic stimulation. It was not possible to prove an influence of nicotine on the automatism of the myocardial tissue. A. E. Meyer

Variations of iodine and bromine in the thyroid of animals treated with bromine. Giovanni Moruzzi. *Arch. fisiol.* **39**, 249–73(1939); cf. *C. A.* **33**, 3887[1].—Br is a normal constituent of animal organs, but the quantity is usually too small to permit an estn. as to whether it is specific for the organ. Feeding NaBr to dogs and rabbits leads to a selective accumulation in various organs, especially the pituitary, gonads and thyroid. Prolonged medication produces in most organs a gradual increase which reaches a max. after a long time and is followed by a slow decrease. The thyroid attains the max. quite rapidly and a prompt and sustained decrease follows, which may attain finally 98% of the initial max. The Br is usually present in a nondialyzable form. A. E. Meyer

The mechanism of the disappearance of the vasomotor reflexes of the carotid sinus produced by ergobasine. Leonardo Donatelli. *Arch. fisiol.* **39**, 327–66(1939).—Ergobasine depresses the vasoconstrictor bulbar centers; in small doses it sensitizes the muscular receptors to adrenaline-like substances. In large doses it depresses them. A. E. Meyer

Modifications of basal metabolism in pernicious anemia during liver therapy with special reference to the change in the blood picture. Pier M. Casassa and Giulio Saita. *Arch. sci. med.* **68**, 563–82(1939).—There is in pernicious anemia a general trend toward a lower metabolic rate, but the acute cases show rather an increased rate. The peripheral blood picture itself does not correspond to definite changes in the metabolic rate. During the reticulocyte crisis an increase occurs which is followed by a decrease while the blood count improves. Later on an increase follows again. A normal blood count does not entail normal metabolism. A. E. Meyer

Effect of certain drugs and mineral deficiencies on helminthiasis of ruminants. Karam Chand. *Indian J. Vet. Sci.* **9**, 267–78(1939).—The following cheap anthelmintics, singly and in combinations, were tried against *Haemonchus* and *Oesophagostomum* in calves and sheep: powd. butea, $CuSO_4$, kamala, melon (pumpkin) seeds, spineless cactus, turpentine oil, veronica anthelmintica and Na arsenite. The most effective was $CuSO_4$ with kamala, which lowered the egg count of the parasite in calf and sheep feces 90%. $CuSO_4$ with Na arsenite eradicated 58% of the parasites. Mineral deficiencies in the diet lowered the resistance of the animals to parasitic infestation. Dorothy A. Meyer

The effect of sulfanilamide and sulfapyridine on a toxic lyzate derived from pneumococci. Charles M. Carpenter, Gerald M. Barbour and Helen Ackerman. *J. Bact.* **39**, 27–8(1940).—When 1 mg. of sulfanilamide was mixed with 1 m. l. d. of type I toxic lysate 95% of the mice died as compared with 96% of the controls. With sulfapyridine only 12% died. With type III lysate 93% of the controls died and none with sulfapyridine. J. T. M.

Some relations of chemical structure to toxicity and to antibacterial action. Sanford M. Rosenthal and Hugo Bauer. *J. Bact.* **39**, 28(1940).—The S in sulfanilamide may be replaced by As, C or P and active compds. obtained. As regards the amino group, the *p*-position in the benzene group seems to be essential. Oxidation of the amino group does not decrease activity but increases toxicity. John T. Myers

The effect of sulfanilamide and its derivatives (sulfanilylsulfanilamide, the soluble sodium salt of this compound and sulfapyridine) on the gonococcus and gonococcal infections. A. Cohn. *J. Bact.* **39**, 44–5(1940); cf. *C. A.* **33**, 2978[8].—Expts. *in vivo* and *in vitro* indicate only slight differences between the different chemotherapeutic agents on single gonococcus strains. A given patient may be resistant to one compd. and responsive to another. John T. Myers

Study of mouse temperatures, with reference to the effect of temperature on sulfanilamide therapy. W. P. Larson, Milton Levine, Raymond M. Bieter and Wm. F. McLimans. *J. Bact.* **39**, 45(1940).—Infected mice treated with sulfanilamide lived longer at room temp. than at 37°. John T. Myers

Pathological changes following prolonged administration of sulfathiazole and sulfapyridine. Geoffrey Rake, H. B. van Dyke, W. C. Corwin, C. M. McKee and R. O. Greep. *J. Bact.* **39**, 45–6(1940).—Sulfathiazole caused fewer pathol. changes than did sulfapyridine. John T. Myers

Tutin: its pharmacological action and its antagonism to sodium amytal. Edward E. Swanson. *J. Am. Pharm. Assoc.* **29**, 2–4(1940).—Tutin, $C_{20}H_{23}O_8$, a glucoside of *Coriaria thymofolia*, has a convulsant action similar to that of coriamyrtin and picrotoxin; it is slower in the onset of action but longer in duration. Comparisons were made with coriamyrtin, picrotoxin, metrazole and thujone, in mice and rabbits, by the detn. of convulsive and lethal doses, injected subcutaneously and intravenously. In rabbits Na amytal can detoxify 55 min. lethal doses of tutin, 45 of coriamyrtin, 40 of picrotoxin, but only 7.5 of metrazole and 5 of thujone. Intravenously, tutin can detoxify in rabbits a little more than 2 min. lethal doses of Na amytal injected subcutaneously. A. P.-C.

Toxicity of triethylene glycol and the effect of *p*-aminobenzenesulfonamide upon the toxicity of this glycol. W.

M. Lauter and V. L. Vrla. *J. Am. Pharm. Assoc.* 29, 5–8(1940).—Triethylene glycol (I) is less toxic than diethylene glycol when given to rats; it is therefore doubtful that the ether linkage in the higher glycols is responsible for the increase in toxicity reported previously. The lethal dosage when given by stomach tube undild. is between 10 and 15 cc. I per kg. body wt.; 10 cc. per kg. shows definite toxic symptoms and retards wt. increase. Aq. solns. do not seem to be more toxic than when I is given undild. Adult rats are killed by 5% solns. while young rats barely survive this concn. Young rats thrive well on 3% solns. and the increase in wt. is absolutely normal. In view of the fact that as low as 0.25% of diethylene glycol showed impairment of growth in rats, further investigations of I and higher mol. wt. glycols would seem worth while. A. Papineau-Couture 1

Pharmacologic study of devil's club root (Fatsia horrida). Leonard J. Piccoli, Michael E. Spinapolice and Morris Hecht. *J. Am. Pharm. Assoc.* 29, 11–12(1940).—Oral administration of aq. exts. of devil's club root had no hypoglucemic effect on the blood of rabbits that had been starved for 15–24 hrs. A. Papineau-Couture 2

The toxicity of a new mercurial diuretic, Esidron. II. Acute toxic effects produced by a massive dose of the drug. L. L. Chastain and George C. Mackie. *Southern Med. and Surg.* 102, 5–6(1940).—No acute toxicity was evident in dogs with up to 7 times the av. human therapeutic dose (2.5 mg./kg.) of Esidron (the sodium salt of *N*-hydroxymercuripropylquinolinamic acid compd. with theophylline). Typical Hg poisoning, with blood pressure and respiratory changes secondary to the cardiac effects, was produced only with 22.5–37.5 mg. of the drug per kg. **III. The effect of continued use of the drug and its diuretic action.** Geo. C. Mackie and L. L. Chastain. *Ibid.* 7–8.—The diuretic action of 6.5 mg. Esidron per kg. rabbit (given intravenously) was not altered by premedication with a series of 2.5 mg. subcutaneous doses per kg.; nor were there any toxic symptoms. Hg metabolism proceeded normally during continued medication with the latter dosage. J. Pinchack 3 4

Mecholyl and histamine effects on peripheral circulation and relief of arthritic pain. Abraham Cohen and Harry Rosen. *Arch. Phys. Therapy* 21, 12–16(1940).—Ointments contg. acetyl-β-methylcholine chloride (I) dilated the capillaries and arterioles of the web of the frog foot. Histamine-HCl (II) dilated the capillaries but in general constricted the arterioles with resultant slowing of the circulation. Ointments contg. II produced satisfactory erythema in arthritic patients but caused urticaria in 4 cases, 3 of whom presented previous histories of allergy. I ointments produced erythema in all patients with no untoward reactions. Both I and II produced a greater effect when they were incorporated in an analgesic-balm type of base, compd. menthol ointment, than in a petrolatum-lanolin base. Heat enhanced the action of both drugs. An ointment contg. 0.25% I used with the application of heat relieved arthritic pain resulting from circulatory disturbances in 88% of 96 cases. M. M. R. 6 7

Signs of intoxication after use of minute quantities of atropine. W. Müller. *Med. Welt* 13, 1230–1(1939).—Toxic symptoms developed in 3 patients when ointment containing atropine (0.2–1 mg.) was introduced into the conjunctival sac. In one patient, toxicity was noted when 0.7 mg. of atropine was taken orally. The described sensitivity to such small doses is contrasted to the great tolerance of patients with parkinsonism and postencephalitis who are known to tolerate up to 40 mg. daily. Maurice M. Rath 8

Treatment of multiple sclerosis with lecithin. I. Miner. *Münch. med. Wochschr.* 86, 1038–40(1939).—Lecithin (10–20 mg. in 5 cc. of physiol. saline soln.) was injected intrathecally in persons with disseminated sclerosis with considerable improvement in 80% of 130 cases. Lecithin has a specific antilipase activity and is an activator of cellular processes in the organism. Both of these reactions probably account for its favorable therapeutic action. It may be that lecithin acts further to inactivate the pathogenic virus by fixation of the pathol. lipase to an exogenous substrate. Administration by this method caused no apparent toxic reactions. Maurice M. Rath 9

The significance of neurovegetative disturbances in throat, nose and ear diseases and their treatment with Bellergal. Gerhard Theissing. *Münch. med. Wochschr.* 86, 1121–3(1939).—Bellergal, a combination of bellafolin and ergotamine, together with phenobarbital, gave good results in patients suffering from migraine and Ménière's disease. Complex disturbances of the autonomic nervous system, which apparently is hyperactive, are benefited by the use of the 3 drugs, which are used because they act favorably on both the vagus and sympathetic systems. Maurice M. Rath 10

Effect of potassium chlorate upon poliomyelitis experimentally produced in the monkey. C. Contat and C. Spycher. *Schweiz. med. Wochschr.* 69, 719–22(1939).—A virulent poliomyelitis strain was inoculated intracerebrally into *Macacus rhesus*, all of which died in 7–11 days after inoculation. To the virus suspension, *in vitro*, was added $KClO_3$ (2.5–5.0%) for 2 hrs. Injection of the suspension had no effect. When $KClO_3$ (0.1 g. per kg. body wt.) was given by mouth every 2 hrs. 100 hrs. after inoculation, poliomyelitis appeared to be checked. Given within 48 hrs. after injection, $KClO_3$ prevented poliomyelitis from developing. Animals cured by $KClO_3$ proved immune to a second inoculation 10–15 days after the first injection or end of treatment. Five to 10 times the therapeutic dose for humans proved nontoxic in monkeys. $KClO_3$ was successfully used to treat 40 patients with acute poliomyelitis. M. M. R. 11

Effect of diethyl- and allylisopropyl-barbituric acid on control of blood sugar. Z. Horn. *Schweiz. med. Wochschr.* 69, 741–2(1939).—See *C. A.* 30, 6825⁸. Maurice M. Rath 12

Hydrocyanic acid poisoning: acute segmental edema of the cornea, Kayser-Fleischer's ring and renal diabetes. M. Amsler. *Schweiz. med. Wochschr.* 69, 1012–15(1939).—After being exposed to HCN vapors in a disinfecting room, corneal changes, such as opacity and radial strips, were noted in 1½ hrs. Sugar (5%) was found in the urine but this disappeared quickly, although functional disturbances of the kidneys were still noticed a year later. Maurice M. Rath 13

Action of tyrosine and glycocoll on the blood-sugar content in Eck-fistula dogs. Toei Ka. *Tôhoku J. Exptl. Med.* 37, 113–18(1939); cf. Kesztyüs and Martin, *C. A.* 31, 3151⁹.—The blood-sugar level in the normal dog was not changed by the intravenous administration of 0.1 g. per kg. of tyrosine. In the Eck-fistula dog this amt. produced a slight hyperglucemia followed by a slight hypoglucemia. In the normal dog 0.1 g. per kg. of glycocoll produced a long-continued hypoglucemia and no hyperglucemia, in the Eck-fistula dog a slight elevation occurred, followed by hypoglucemia. A slight but definite hyperglucemia followed by a slight hypoglucemia resulted when 0.5 g. per kg. glycocoll was given. In general, there was an increase in the blood-sugar concns. after giving tyrosine or glycocoll to the Eck-fistula dog. The hypoglucemic effect of glycocoll is not altered by that operation. Maurice M. Rath 14

Influence of pilocarpine on the adrenaline output from the suprarenal glands in dogs and cats. Takuzi Hirano. *Tôhoku J. Exptl. Med.* 37, 119–38(1939).—Pilocarpine was administered to cats and dogs provided with a cava pocket. One mg. per kg. given subcutaneously evoked an accelerated effect on the output of adrenaline in the dog; given intravenously, 1–2 mg. per kg. accelerated the adrenaline output in anesthetized dogs, but the amt. was small and acceleration occurred much sooner than in the nonanesthetized dogs. In cats 1 mg. per kg. was not effective, whereas 2 to 5 mg. usually was. In the cava-pocket expt., which is carried out under anesthesia and laparotomy, the rate of adrenaline output was decidedly reduced when a small amt. of the drug was given. Intermediate amts. caused a transitory reduction followed by an acceleration. The blood flow through the suprarenals in both cats and dogs was usually diminished after giving pilocarpine. Maurice M. Rath 15

Gonorrheal myelitis with associated porphyrinuria following sulfanilamide. Frank G. Norbury. *J. Lab. Clin. Med.* **25**, 270–4(1939).—The urine of a patient with gonorrheal myelitis who had taken sulfanilamide contained porphyrin pigments, which were confirmed by spectroscopic examn. Howard W. Robinson 1

The hematologic study of seventy-six pneumonia cases treated with sulfapyridine, including a fatal case of agranulocytosis. J. R. E. Morgan and H. K. Detweiler. *J. Lab. Clin. Med.* **25**, 275–81(1939).—The drug produced no significant decrease in hemoglobin or erthrocyte levels. Of 35 patients with a persistent leucocytosis after the third day of therapy, 65% had a demonstrable complicating factor and of these 46% were pulmonary in character. Leucopenia was present in 8 patients. When the total leucocyte count fell to 4000 there was a relative lymphocytosis; below this level the lymphocytic and granular series were reduced in total nos., maintaining the relative lymphocytosis. The leucopenia could not be correlated to age, sex, causative organism, dosage, or blood levels of the drug, but patients with low initial leucocyte counts are much more liable to leucopenia. A case of sulfapyridine-treated hemolytic streptococcal pneumonia, which developed a fatal agranulocytosis, is reported in detail. Howard W. Robinson 2

Pharmacology of tetanus toxins. Syotin Haku. *J. Chosen Med. Assoc.* **29**, 2025–74(German abstr. 129–32) (1939).—The active principle of the toxins which cause the typical tetanus in mice decomps. at 60–70° (60 min.). The toxins also contain a principle which has the power to accelerate at a high temp. the movement of isolated heart of bullfrog; this principle is inactivated at 80°. It acts on intracardial ganglionic cells. A new perfusion app. having devices for maintaining const. temp. at different temps. is described. S. Tashiro 3

The influence of wrapping the gastric vagus nerve with magnesium strips on the secretion of the gastric pouch. Takeo Yositosi. *J. Oriental Med.* **31**, 767–85(English abstr., 54)(1939).—From 2 to 3 weeks after wrapping with Mg strips the vagus nerves (below the diaphragm) of dogs having a gastric pouch, there is a marked decrease in gastric function, as judged by acidity, peptic activity and amt. of secretion. Contrary to Best and Orator's finding, the effect is paralytic not stimulatory. This effect is not local but general owing to the absorption of Mg salts produced by oxidation of the metal. S. Tashiro 4

Selective action of sulfanilamide on the parasites of experimental malaria in monkeys in vivo and in vitro. L. T. Coggeshall. *J. Exptl. Med.* **71**, 13–19; *J. Bact.* **39**, 30–1 (1940).—With mixed malaria infections in the same exptl. animal sulfanilamide (I) eradicates a virulent *P. knowlesi* (II) infection, leaving the animal with a milder chronic *P. inui* (III) infection. Detns. of the metabolic activity of the 2 parasites *in vitro* showed that II consumed approx. 6 times more O than III. The addn. of I in concns. less than that necessary to effect a cure almost completely inhibited the respiration of I *in vitro*, whereas the same concn. of I against the same no. of III had no apparent effect. C. J. West 5

Chemical and immunological studies on the agent producing leucosis and sarcoma of fowls. Elvin A. Kabat and Jacob Furth. *J. Exptl. Med.* **71**, 55–70(1940); cf. *C. A.* **33**, 3778[8].—The activity of the agent producing sarcoma or leucosis in material deposited by high-speed centrifugation is the same as that of the original crude exts. Material sedimentable at high speed contg. approx. 10^{-6} mg. N produces tumors at the site of injection. Small quantities of material sedimentable at high speed are present in normal chicken serums and about twice as much in leucemic serums (strain 1). Normal chicken and mouse spleens and all other human and mouse tissues examd. contain large amts. of material sedimentable at high speed. Extn. of leucemic blood cells with saline yields little addnl. virus. The washed cells readily produce leucosis even after irradiation with amts. of x-rays sufficient to destroy the leucemic cells but not the virus. Freezing at −60° preserves the activity of the high-speed deposits for at least 6 months. Addn. of 5% satd. Na_2SO_4 slightly delays deterioration of high-speed deposits in the ice box. Most of the agent measured by inoculation of chicken and the fraction sedimentable at high-speed measured by its N content is pptd. by 1/3 satn. with Na_2SO_4. C. J. West 6

Detection and estn. of benzedrine (Illing) 7. Vitamin K-active derivs. of 2-methyl-1,4-naphthohydroquinone (Ansbacher, *et al.*) 10. Water-sol. antihemorrhagic esters (Fieser, Fry) 10. Sympathicomimetics (Novelli) 10. S studies—synthesis of alkanesulfonic acids and derivs. [tested for therapeutic and antipyretic action] (Latimer, Bost) 10. 7

I—ZOÖLOGY

R. A. GORTNER

The treatment of paragonimiasis. I. Experimental treatment and efficacy in dogs harboring lung flukes (Paragonimus westermanii). Sadamu Yokogawa and Mantoku Ro. *Acta Japon. Med. Tropical.* **1**, 1–18 (1939)(in English).—Intramuscular injections of prontosil sol. combined with emetine-HCl were more satisfactory than emetine alone in the treatment of dogs experimentally infected with lung flukes. The rapid death of the adult flukes was due to the parasiticidal action of emetine, causing degeneration of the adult worms, and to the action of prontosil in stimulating antibody production in the host. Where treatment was successful, varying degrees of transformation and degeneration of some of the eggs occurred on the 3rd day of treatment. The toxic manifestations were due chiefly to the emetine. The treatment was more effective, the lighter the infection, the longer the interval after the initial infection and the more vigorous the production of antibodies in the host. Ruth Berggren 10

The anaerobic consumption of glycogen in male and female Ascaris (from swine). Mantoku Ro. *Acta Japon. Med. Tropical.* **1**, 29–36(1939)(in English).—In 20 expts. on 167 male and 150 female *Ascaris lumbricoides* the glycogen content varied from 3.78 to 6.74% (av. 5.37%) in the males and from 3.55 to 6.67% (av. 4.99%) in the females. The av. daily glycogen consumption per 100 g. fresh *Ascaris* for the 1st, 2nd and 3rd days of starvation under anaerobic conditions at 37° was 1.31, 0.15 and 1.17 g., resp., for the males and 1.33, 0.60 and 0.14 g., resp., for the females. Ruth Berggren 11

The effect of potassium cyanide on the rate of regeneration in Planaria. J. Bassina. *Bull. biol. méd. exptl. U. R. S. S.* **3**, 184–8(1937).—Regeneration was inhibited by KCN. S. A. Corson 12

Advances in entomology. C. H. Richardson. *News Ed. (Am. Chem. Soc.)* **18**, 64–7, 70–2(1940).—A review with bibliography of 93 references. E. J. C. 14

The lipides of Taeniarhynchus saginatus. I. A. Smorodintsev and K. V. Bebeshin. *Bull. soc. chim. biol.* **21**, 1194–1203(1939); cf. *C. A.* **33**, 5520[2].—About 3/4 of the total lipide ext. consists of neutral fats. The remainder is a mixt. of cholesterol, cholesteryl esters, lecithin, cephalin and cuorin. L. E. Gilson 15

Experimental reversal of sex in salamanders by the injection of estrone. Richard J. Ackart and Stanley Leavy. *Proc. Soc. Exptl. Biol. Med.* **42**, 720–4(1939).— 16

The injection of cryst. estrone into young larvae of *Amblystoma tigrinum* in some cases converted the gonads into ovo-testes resembling retarded ovaries with irregular medullary remains. L. E. Gilson

Respiratory exchange of the fresh-water annelid, Tubifex. Fred G. Brazda. *Proc. Soc. Exptl. Biol. Med.* **42**, 734–6(1939). L. E. Gilson

Oxygen consumption of the parts of the amphibian gastrula. L. G. Barth. *Proc. Soc. Exptl. Biol. Med.* **42**, 744–6(1939).—Preliminary. L. E. Gilson

Thyroid treatment and the cyclostome endostyle. Miriam Stokes. *Proc. Soc. Exptl. Biol. Med.* **42**, 810–11 (1939).—Expts. indicate that although the adult lamprey possesses an active thyroid, the body cells of the young ammocoetes, including the cells of the endostyle, are not sensitive to thyroid treatment. Metamorphosis in cyclostomes is related to influences other than the developing thyroid. L. E. Gilson

Effects of testosterone propionate on the female viviparous teleost, Xiphophorus helleri Heckel. Francis M. Baldwin and Howard S. Goldin. *Proc. Soc. Exptl. Biol Med.* **42**, 813–19(1939).—Sex reversal was produced in about 50% of the treated fish. L. E. Gilson

Effect of α-dinitrophenol on the development and metamorphosis of amphibians. M. Aloisi. *Boll. soc. ital. biol. sper.* **14**, 638–9(1939). Helen Lee Gruehl

Changes in plasma inorganic phosphate associated with endocrine activity in Xenopus laevis. II. The effect of insulin in hypophysectomized animals. Velva Schrire. *S. African J. Med. Sci.* **4**, Feb. Suppl. 1–3(1939); cf. *C. A.* **33**, 7598.—Inorg. phosphate was estimated by Youngsburg's method (*C. A.* **25**, 1857). Hypophysectomy was performed by Hogben and Slome's method. Only the anterior lobes were removed. Controls were subjected to all stages of hypophysectomy up to, but not including, removal of the anterior lobe. The animals were injected with insulin 2 months after operation. The water was changed every day and the animals were fed with minced meat twice a week. The animals were not fed for one week prior to the insulin injections. More blood was obtained from the animals if they were not fed during the preceding week. About 50 hypophysectomized animals were each injected intraperitoneally with 2 units of cryst. insulin, contd. in 0.25 cc. frog Ringer soln. and controls with frog Ringer soln. only. The injection of insulin into the animals with the pituitary intact leads to a fall in blood inorg. phosphate (from 5.2 mg. % to 3.2 mg. %, with an increase to 4.2 mg. % after 50 hrs.). A smaller fall was obtained in hypophysectomized animals. This difference can be attributed to the diminished action of adrenaline in hypophysectomized animals. Eleven references. **III. Injection of adrenaline into normal and hypophysectomized animals.** *Ibid.* 4–8.—Each of about 70 hypophysectomized animals and the same no. of operative controls injected intraperitoneally with 100 γ adrenaline in 0.25 cc. Ringer soln. A transient secretion of mucus was observed in both types after 2 hrs. The injection of adrenaline led to an initial fall in plasma inorg. phosphate (from 5.2 mg. to 4.5 mg. %) followed by a rise above normal level (to 5.6 mg. %). Removal of the anterior lobe of the pituitary abolished the initial fall but did not affect the subsequent rise. Eighteen references. W. R. Henn

Purification of the chromatophorotropic hormone of the crustacean eyestalk. A. A. Abramowitz. *J. Biol. Chem.* **132**, 501–6(1940); cf. *C. A.* **31**, 6350⁸.—The chromatophorotropic hormone of the eyestalk of the fiddler crab, *Uca pugilator*, is probably a nitrogenous base and its purification has been effected on the basis of its basic properties. It has been purified 100- to 200-fold by pptg. inert material with $Ba(OH)_2$ or Pb subacetate from aq. exts. and further removal of impurities by adsorption on fuller's earth. The active substance is pptd. in the histidine Ag fraction and then converted into the phosphotungstate which is decompd. and the hormone is dissolved in alc. in a slightly alk. medium and dried. The activity of the dried material was from 200,000 to 400,000 *Uca* units per mg. A. P. Lothrop

X-ray diffraction studies of nerve axis cylinder. F. O Schmidt, R. S. Bear and G. L. Clark. *Biodynamica* No. **50**, 1–3(1939); cf. *C. A.* **31**, 8032⁴·⁵.—Squid nerve axons shrunk in dil. EtOH exhibit a diffuse ring at 10, and a sharp ring at 4.7 A. with Cu Kα radiation. Evidence of orientation was not found. J. McAfee

The ability of the tadpole to stabilize ascorbic acid (vitamin C) and the role of ascorbic acid in the development of the frog. Paavo Suomalainen. *Ann. Acad. Sci. Fennicae* **A53**, No. 9, 12 pp.(1939).—The freshly laid undivided eggs of *Rana temporaria* do not contain ascorbic acid (I). Synthesis of I commenced upon the development of the egg. Max. values for I were noted in tadpoles which had just freed themselves from the jelly and possessed external gills. I decreased during later stages of development. No significant difference was observed in the content of reduced or total I in tadpoles which had developed in mannose or glucose soln. or in H_2O. I had a slight growth-promoting effect on tadpoles. No changes were observed in the rate of development when the tadpoles were kept for 10 days in an aq. soln. of I. Tadpoles secreted into the aquarium H_2O a substance which stabilizes I. H. J. Prebluda

The biology of the Porifera from the standpoint of radiation. W. Arndt. *Sitzber. Ges. naturforsch. Freunde Berlin* **1936**, 315–55(Pub. 1937).—An extensive review on the effects of different wave lengths and intensities of radiation (mostly visible light at different depths of fresh and salt water) upon respiration, pigmentation and other chem. and physiol. phenomena in sponges. Over 100 references. W. C. Tobie

Diffusion of chloride and glucose into frog muscle. R. B. Fisher and V. Subrahmanyan. *J. Physiol.* **97**, 233–7(1939).—The diffusion of Cl and glucose into the gastrocnemii of Hungarian frogs occurs *in vitro* in stages which are similar in magnitude for the 2 substances but sepd. in time. The Cl permeation of the muscle is always greater than that of glucose. E. D. Walter

12—FOODS

H. A. LEPPER

Calorific value of Indian foodstuffs. K. P. Basu and M. C. Malakar. *J. Indian Chem. Soc.* **16**, 427–32(1939).—The calorific value, moisture and N content of about 100 common Indian foodstuffs were detd. and reported. The calorific values were detd. by the Benedict-Fox oxycalorimeter (cf. *C. A.* **19**, 3040); and in the calcns., the calorific value of 1 l. of O_2 was taken to be 4.825 cal. D. A. M.

Review: The significance of physical methods of preservation for food hygiene. M. Knorr. *Jahreskurse ärtzl. Fortbild.* **30**, No. 10, 1–13(1939).—A brief discussion of the use of cold, either alone or combined with inert gases (CO_2 or N_2), dry ice, freezing, heat, desiccation and sterile filtration in the preservation of foods, and the effects of some of these methods on certain food components, as vitamins, minerals, proteins and enzymes. Ruth Berggren

Chemical preservatives and their determination in food products. V. S. Kobzarenko. *Akad. Nauk. U. S. S. R., Inst. Khem. Tekhnol.* (Kiev) **1939**, 113 pp.(English summary).—The history, toxicity, physiol. action and legislative regulation of food preservatives are reviewed. A new volumetric method for detn. of HCO_2H is based on the reactions $HCOONa + 2HgCl_2 = 2HgCl + NaCl + HCl + CO_2$, and $HgCl_2 + 2NaOH = HgO + 2NaCl + H_2O$. The method described is accurate to ±2.81%. The bromometric method ($HCOOH + Br_2 = 2HBr + CO_2$) is simpler. The results are accurate to ±0.81%, with a total acid content of 18 mg. In tests on preserved

sirups, the error averaged 4–7%; this is much better than the standard method used heretofore, where the error was as high as 17%. Benzoic acid does not interfere, but formaldehyde, salicylic and sulfurous acids do. The bromometric method for formaldehyde in an acetate medium ($CH_2O + 2Br_2 + H_2O = 4HBr + CO_2$), gives satisfactory results, permitting the detn. of 30–5 mg. of formaldehyde. Hexamethylenetetramine can be detd. only in aq. solns.; in the analysis of food products such detn. is difficult. The tryptophan reaction permits the detection of minute quantities, and in doubtful cases micro reactions are practical. Shake 20–30 g. of the finely divided product with 200 cc. of water and after 1.5 hrs. transfer to a 500-cc. flask, acidify with 10 cc. 25% phosphoric or 1 cc. sulfuric acid (1:4), and distil off 50 cc. with steam. Salicylic acid is detd. with an error less than ±2% by evapg. a petr. ether ext., taking up with 10 cc. H_2O, neutralizing with 0.05 *N* KOH, evapg. on a water bath in a Pt dish, igniting, dissolving in 15 cc. H_2O and titrating with 0.1 *N* HCl and methyl red. An iodometric method depends on the formation of $C_6H_2I_2(OI)CO_2Na$, which on addn. of NaOH forms $C_6H_2I_2(ONa)CO_2Na + NaIO + H_2O$. The NaIO is titrated with thiosulfate; error 0.8–1.5%. For benzoic acid the method of Fischer and Stauder (*C. A.* **25**, 1001) gives low results in fruit products, alcohol-free juices and pastries, in the presence of proteins. Schwaibold's method (*C. A.* **26**, 5670) modified by K. was more satisfactory. Thirty g. of the finely divided substance was heated 20–30 min. with 25 cc. H_2O and a few drops of phenolphthalein, 0.5 *N* NaOH added to faint alky., the mixt. cooled, shaken with 30 cc. of 15% $K_4Fe(CN)_6$, and 30 cc. of 30% $ZnSO_4$. The proteins were pptd., the flask was filled to the mark, and 50 cc. of the clear liquid was transferred to a funnel, weakly acidified with H_2SO_4, vigorously shaken for 2–3 min. with 40 cc. benzene, then with 20, and again with 10 cc. Up to 97% of the acid was thus extd. The benzene was distd. from the ext. made weakly alk. with 0.5–1 cc. *N* KOH. The benzoate was purified by extg. with ether the soln. acidified with HCl. The carbonate method of estn. gave much better results than the colorimetric. The ether ext. was evapd., taken up with 10 cc. of water, neutralized with 0.05 *N* NaOH and methyl red, evapd., ignited with KNO_3 for 15–20 min. to Na_2CO_3, taken up with water and titrated with 0.02 *N* HCl and methyl red to pale pink. Methods of detection and estn. of *p*-hydroxy- and *p*-chlorobenzoic and cinnamic acids are evaluated and described, as well as those for H_2O_2, F, boric acid and borax. 120 references. B. Gutoff

Flavor in food: A technical analysis of the sensation of flavor, presenting current theories and relating experiments that may lead to new developments in the extract field. Gordon R. Maybee. *Spice Mill* **62**, No. 7, 40–44 (1939); cf. *C. A.* **33**, 3899[4]. G. Adams

7

Reduction-oxidation potential indicators in quality control of foods. I. Correlation of resazurin reduction rates and bacterial plate counts as indexes of the bacterial condition of fresh and frozen foods. Bernard E. Proctor and David G. Greenlie. *Food Research* **4**, 441–6(1939).—A modified resazurin technique is useful in providing a fairly rapid and moderately accurate means of detecting foods contg. large nos. of bacteria. Extremely high counts can be detected in 30 min. in such products as comminuted meats and broken-out eggs. Com. applications of the method are pointed out. C. R. Fellers

8

Quantitative determination of tin in foods. E. Mathiesen and F. Jakobsen. *Tids. Kjemi Bergvesen* **19**, 147–50(1939).—The volumetric detn. of tin in the residue after wet ashing ($H_2SO_4 + HNO_3 + HClO_4$) of foods, especially canned foods, was investigated. Tin is detd. by oxidation with 0.002 *N* $HBrO_3$ after previous reduction with granulated Al in an atm. of CO_2. The optimal conditions of analyses have been settled, in particular with regard to the rapid accomplishment of the detn. H. Kringstad

9

Selenium in vegetation; a search for the element in New South Wales wheat. M. S. Benjamin and A. W. Miles. *J. Australian Inst. Agr. Sci.* **5**, 221–3(1939).—No more than a trace of Se was present in any one of 20 wheat samples obtained from the chief wheat-producing districts of New South Wales. J. R. Adams

Some suggestions on the value of the determination of germination capacity and its practical accomplishment by the selenium method. Barthold Thomas. *Z. ges. Getreidew.* **26**, 155–9(1939).—Two modifications of the method (cf. *C. A.* **32**, 8012[8]) are suggested to obviate the tedious procedure of sectioning the individual grains. By one procedure the seeds are treated briefly with concd. H_2SO_4. After thorough neutralization with $NaHCO_3$ the seed coats are made to slip off easily by treatment with acetone. Since the concd. acid is inconvenient to use in rapid practical tests, an alternative measure is to soak the seeds (duplicate samples of 100 grains each) in 25% H_2O_2 for 2 hrs. The seed coats are sufficiently softened to permit adequate penetration by soaking at 37° overnight in a 2% soln. of the reagent ($NaHSeO_3$). By subjecting the seeds to a 2-min. evacuation under the water pump the seed coats over the embryos become taut and transparent so that any red coloration can easily be observed. Results by the 2 methods presented in comparison with those obtained by the standard germination technique (percentage germination after 10 days on moist sand), indicate an accuracy within 10%, which is considered sufficient. G. Adams

Chemical methods in the evaluation and testing of cereals and cereal products. U. Hanke. *Mühlenlab.* **9**, 17–22, 81–8(1939).—A summary of the more important methods with comments on their suitability and accuracy. G. Adams

The glutenous wheat investigations of the Reich's institute for cereal milling. Ernst A. Schmidt and A. Schulz. *Z. ges. Getreidew.* **26**, 148–51(1939).—Information is given for a no. of varieties of summer and winter wheats of the 1938–39 harvest concerning the no. and percentage of samples classified as glutenous wheat. Averages are reported by varieties for gluten content, swelling capacity and test no. G. Adams

Translocation of moisture in the bulk of stored grain. A. Kizel, N. Vasil'eva and G. Tsygankova. *Compt. rend. acad. sci. U. R. S. S.* **24**, 786–90(1939)(in English).—Seeds of a soft variety of spring wheat were immersed in water on a strainer and allowed to dry on a thick cushion of gauze and thoroughly dried in thermostats at 28.3°, in layers 4–5 cm. thick. The expt. was conducted in 6-l. flasks insulated with felt and oil cloth and provided with wooden lids. A little refrigerator was designed to pass through the lid and cool the grain locally. The lid was pierced by a thermometer. The cooled portion of the grain was isolated in a gauze bag impregnated with paraffin. The bag was filled with about 60 g. of the same grain contained in the vessel. The refrigerator was a short cylindrical glass vessel of about 20–25 cc. capacity with 1 inlet and 1 outlet tube sealed in and insulated from the rest of the grain by a double-glass muff closed hermetically. The figures obtained show that grain gives off water to its cooled portions. Small differences in temp. suffice to bring about such translocation even in cases where the water content of the grain is extremely low. The importance of this fact for grain storage is pointed out and also the necessity of a uniform temp. throughout its vol. A. H. Krappe

The applicability of the colorimetric maltose determination in the recognition of germination injury in cereals and flour. K. Trognitz. *Z. ges. Getreidew.* **26**, 172–6(1939).—The chem. changes in cereal grains resulting from germination are discussed. The maltose content as detd. by the method of Schmidt (cf. *C. A.* **33**, 8435[7]) is considered a reliable index of germination injury. G. Adams

Clove oil as a mounting medium in microscopy for rapid detection of traces of flour from sprouted and malted grains. Ernst Berliner. *Mühlenlab.* **9**, 87–90(1939).—For rapid microscopic evaluation of flours clove oil is recommended as a mounting medium. The hollow spaces

arising in starch grains corroded through diastatic hydrolysis appear so prominent in clove oil that each grain so attacked can be readily recognized in transmitted light even at low magnification. The punctiform or crater-shaped depressions of corn starch are scarcely to be confused with the picture of the corroded grains. From a study of clove oil mounts B. concludes that the clefted hilum described in the literature as especially characteristic of rye and legume starches is not preformed but occurs only in water and other starch-swelling media as a consequence of suddenly occurring expansion within the grain. G. Adams

Three methods for determining foreign matter in flour. Bernard L. Blumberg and Charles W. Ballard. *Food Ind.* **12**, 36–8(1940).—Methods are described for detecting the eggs, excreta and larvae of the confused flour beetle, *Tribolium confusum*, in flour, are described. C. R. Fellers

Artificial bleaching of flour. G. Destrée. *Ann. zymol.* **6**, 314–36(1939).—A review of the action of the various bleaching agents used on the constituents of flour and of methods of detecting these agents. A. Papineau-Couture

The content of vitamin B_1 of Latvian white flours and breads of various milling grades. E. Zariņš and I. Robežniece. *Acta Univ. Latviensis, Kim. Fakultat. Ser.* **4**, No. 9(in Lettish, 423–8; in German, 429–30)(1939).—Latvian flour mixts. and breads prepd. from these mixts. were analyzed by converting the vitamin to thiochrome according to the Jansen method. The mixts. contg. (*a*) 97%, (*b*) 67–78, (*c*) 50–67 and (*d*) 0–50% white flour contained (*a*) 369, (*b*) 424, (*c*) 218 and (*d*) less than 50 γ of vitamin B_1 per 100 g. of the dry flour. The breads prepd. from these resp. flours contained (*a*) 290, (*b*) 391, (*c*) 230 and (*d*) less than 50 γ of vitamin B_1 per 100 g. of dry bread; black bread contained 249 γ. Bran contg. flours and breads contained very small quantities of vitamin B_1. The cocarboxylase content of the flours and breads was smaller than the smallest quantity which can be detected by the Roth method. Frank Maresh

Bread baking test suggested for pastry flours. J. A. Shellenberger. *Food Ind.* **12**, 52–4(1940).—The standard baking test of the Am. Assocn. of Cereal Chemists, Cereal Lab. Methods, 3rd Ed., is recommended for use in the lab. testing of soft-wheat pastry flours in preference to making test-cake batches. The nature and character of the test loaves, though not perfect, give much helpful information. C. R. Fellers

Preparation and evaluation of potato starch flour. Waldemar Kröner. *Z. ges. Getreidew.* **26**, 162–70(1939). —The article gives a flow sheet and detailed description of the present German process for manuf. of potato flour. The quality factors, color, odor, gloss, microscopic purity, moisture, ash, acid-insol. ash, active and bound Cl, SO_2 and sulfite, acidity and pH interval are discussed, the limits permissible being noted for the 3 quality grades. G. Adams

The influence of flour maltase on the determination of maltose-forming capacity according to Rumsey. A Rotsch. *Mühlenlab.* **9**, 65–70(1939); cf. *C. A.* **34**, 783[2].—Glucose was not detected in the usual dil. (1:10) ext. of flour, but when a more concd. ext. was prepd. by agitating 3 parts of flour with 5 of water and centrifuging at high speed glucose could be detd. by the reduction of a Cu sulfate–Na acetate soln. (Steinhoff's soln.). In an aq. suspension of flour a continuous increase in the glucose content was observed over a 1–3 hr. period, the amt. formed being dependent upon the temp. and the pH. At 0° there was little or no glucose formation and at a pH greater than 6 the rate of formation was slower than at a lower pH. The glucose:maltose ratio varied from 1:3 to 1:5 or 1:6 in the flours studied. In samples contg. flour from sprouted grain a higher glucose value was obtained along with a higher maltose value, this glucose formation being due apparently to the activity of cereal maltase. Sucrose and maltose solns. were not changed by aq. exts. of flours, except for flours from sprouted grain; such exts. over a longer period could act on a maltose soln. slightly decreasing its rotation. In normal flours, however, the enzyme appeared to be insol. in water. Because of the glucose formation the values obtained in the usual maltose detn. were too high; with wheat flours they were as much as 10% higher than the true values for the maltose-forming capacity. G. Adams

Properties and use of dusting meals. P. Pelshenke. *Mehl u. Brot* **39**, 517–19, 533–6, 549–51(1939).—As substitutes for the coarse-grain meals usually used to prevent sticking in the working and molding of bread dough, 26 meals of various origin are considered from the standpoint of adaptability and suitable purity as indicated by the total and acid-sol. ash content. Meals from spruce, fir, and beach wood, from grain hulls, oat straw, ivory nuts, and coffee grounds are listed, information being given on the ants. to use per kg. of dough, on the vol. in cc. per 100 g. of meal, and on the moisture, total ash, and acid-sol. ash content. G. Adams

Factors which influence the colloidal properties of dough. C. O. Swanson and R. J. Clark. *Kansas Agr. Expt. Sta., 9th Biennial Rept.* **1938**, 67.—The use of a supercentrifuge as a method of detg. absorption of water by flour has now given way to the use of a small mech. mixer. Dough-mixer curves were made on flour on all varieties milled and baked, providing much material for the study of correlation of curve characteristics with baking value. Baking was done by the checkerboard sponge method in units of 36 loaves. An instrument for recording automatically the rate of gas production and retention was used. In general, the recording-dough-mixer curves are characteristic of individual varieties of wheat. Abnormal values were obtained from drought-damaged wheat. When the dough-mixer curves were first used in testing, it was supposed that the peak of the curve represented the end of the mixing time. However, results show that the distance from the start to the peak of the curve represents the sum of all the mech. punishments the dough is to receive in baking, such as mixing, dividing, rounding, molding and stretching during fermentation. After the mixing has proceeded to the top of the curve the dough begins to break. It loses elasticity, probably due to the fact that the gluten strands become too attenuated. The break occurs when these elongated gluten particles begin to sep. The duration curve of the peak stage varies greatly in the different varieties. The rounded-peak curves are preferred to those with a sharper peak. C. R. Fellers

Basic questions on the sour-dough process. J. Lemmerzahl. *Mehl u. Brot* **39**, 273–8, 309–12, 325–8, 342–5(1939).—A survey relating practical procedures to scientific findings. G. Adams

The bacteriological control of dairy produce. P. Clerkin. *Agr. Progress* **16**, 218–23(1939).—The various methods for detg. the quality of dairy products from the bacteriol. standpoint are discussed. K. D. Jacob

Protein standards for milk production. J. Mackintosh. *Agr. Progress* **16**, 195–201(1939).—Under the conditions prevalent on numerous farms in the South of England the protein standard for milk production can be lowered 20–30% without detriment to the condition of the cow and the yield and quality (fat and solids-not-fat) of the milk. K. D. Jacob

Factors affecting the composition of milk. D. H. Jacobsen and G. C. Wallis. *N. Dakota Agr. Expt. Sta., Bull.* **331**, 5–28(1939).—One-day composite samples of milk from individual cows were obtained at monthly intervals for 5 years. These samples were examd. for ash, fat, total solids, Ca and P. Fat, solids and minerals in the colostrum milk were high but variable as compared with normal milk. Milk from Holsteins varied in fat content from 1.5 to 5.5 with an av. of approx. 3.4%; these same values for Jerseys were 3.5–9.0 with an av. of about 5.3%; Guernseys 3.5–8.0 with an av. close to 4.9%; and Ayrshires 3.7–5.2 (approx.) with an av. of about 4.4%. A definite lowering of the fat content was present during the summer months in all breeds. All breeds except Holsteins gave milk of higher fat percentage near the end of the lactation period. With Holsteins the fat

was highest shortly after parturition. Normal values for percentage of total solids for the several breeds were: Holstein 10.5–12.3, Ayrshire 12.5–14.3, Jersey 14–16 and Guernsey 14–16. Holstein milk was often below the legal min. for milk in both fat and solids-not-fat content. Values for ash in mg. per 100 ml. of milk for the several breeds are approx.: Holsteins 690, Ayrshires 709, Jerseys 770 and Guernseys 748. In general, the ash, Ca and P decreased during the 1st month of lactation, remained fairly const. until near the end of lactation, then increased steadily. Av. Ca values expressed in mg. per 100 ml. of milk were: Holsteins 114, Ayrshires 132, Jerseys 146 and Guernseys 146. Values for P were Holsteins 87, Ayrshires 105, Guernseys 108 and Jerseys 112. The increase at the end of lactation for P content was not nearly so marked as for Ca. The mineral content was lowest during the summer months. C. R. Fellers

Determination of ascorbic acid in commercial milks. Warren W. Woessner, C. A. Elvehjem and Henry A. Schuette. *J. Nutrition* **18**, 619–26(1939).—Ascorbic acid was detd. by a modification of the method of Mindlin and Butler (*C. A.* **32**, 2968[9]). The photoelec. colorimeter makes possible the elimination of many of the interfering substances which are formed when the milk is treated with H_2S. Among these substances is reduced riboflavin. No daily variation in the milk of individual cows was observed. Com. raw milks are only slightly less potent in ascorbic acid than fresh raw milks. Pasteurization destroys about 50% of the ascorbic acid present in the raw milk. Mineral modification and homogenization have a destructive effect on ascorbic acid content of milk. C. R. Fellers

Chemical properties of various kinds of milk and the detection of tubercle bacilli in milk. K. Ida. *J. Pub. Health Assoc. Japan* Dec., **1936**, 1–5; *U. S. Pub. Health Eng. Abstracts* **18**, Mi, 7(Jan. 15, 1938).—For detection of *Mycobacterium tuberculosis* the samples were centrifuged and the sediment either inoculated into guinea pigs or else plated out on Petroff's medium. All samples of raw and pasteurized milks gave a peroxidase reaction. Reductase was present in all samples of milk regardless of the temp. of storage. The time required for natural coagulation of the samples was largely dependent on the temp. of storage. In the raw milk catalase was at its max. activity when kept at 20–22°, while in the pasteurized samples max. activity was obtained at 37°. C. R. Fellers

Oily, metallic-flavored milk. Hans Herzfeld and Erich Vollbrecht. *Deut. Molkerei-Ztg.* **60**, 635–6, 670–1(1939).—Processed milk of good flavor stirred 2 min. with a Cu rod in one instance, and with an Fe rod in another, developed, resp., an oily-metallic, and a metallic flavor. Contact of milk with Cu even for one sec. led to the development of a mild oily-metallic flavor. An increase in temp. up to 80° intensified the strength of the off-flavor, and hastened its development. Aeration of the milk weakened the off-flavor and retarded its development. In continuous processing, the milk obtained in the early stages tended more strongly toward the development of the off-flavor than milk obtained in the late stages. Cleaning mixts. corrosive toward tinned equipment influenced the flavor of milk adversely when milk was processed in equipment cleaned with these mixts. The development of the off-flavor bore no relationship to variations in the character of the raw milk. A. Leviton

A modification of the Ritter test for copper in butter. B. E. Horrall and W. F. Epple. *J. Dairy Sci.* **23**, 53–60 (1940).—A modified Ritter test for Cu in butter is described. Results are low when the pH of the butter serum is high. This may be corrected by the use of a small amt. of 0.1 *N* H_2SO_4. Three different classifications were made in the test to det. the extent of the copper contamination: neg., in which the butter contained on the av. 0.221 p. p. m. of Cu and showed no bluish purple in the curd; slight, which had a slight bluish color in the curd and in which the butter contained on the av. 0.291 p. p. m.; and pos., which had a deep blue color and contained on the av. 0.583 p. p. m. The Cu contamination of Indiana butter was found to be 39.1% neg., 39.6% slight and 21.3% pos. The modified test although qual. is fairly accurate in detg. the extent of Cu contamination in butter and is also rapid and inexpensive. A. H. J.

The phosphatase test for control of efficiency of pasteurization. H. D. Kay, R. Aschaffenburg and F. K. Neave. *Milk Plant Monthly* **29**, No. 1, 42–3(1940).—A review. A. H. Johnson

Amylase and phosphatase tests for the efficiency of pasteurization. Arnold B. Storrs. *Milk Sanitarian* **6**, No. 7, 13–14(1937); *U. S. Pub. Health Eng. Abstracts* **18**, Mi, 9(Jan. 15, 1938); cf. *C. A.* **32**, 5088[7].—The amylase test is of definite value in detg. the efficiency of pasteurization. A lack of definite color change, coupled with the tendency of the starch-I blue color to fade rapidly makes interpretation difficult. The amylase test differentiates between heated and unheated milks while the phosphatase test will detect a very small amt. of raw milk in heated milk. Phosphatase is a fairly const. constituent of cow milk; amylase content is more variable. C. R. Fellers

The relation between cooked flavor and peroxidase reactions in milk, skim milk and cream. I. A. Gould. *J. Dairy Sci.* **23**, 37–46(1940); cf. *C. A.* **34**, 1086[9].—A close relationship was observed between the temp. at which the cooked flavor appeared in milk and those at which peroxidase was inactivated, as detected by *p*-phenylenediamine-HCl and guaiac reagents. A similar but less exact relation occurred from skim milk, whereas no relation between the temps. was found to exist in the case of cream. The addn. of sufficient quantities of Na and NH_4 sulfite and glutathione to milk to produce an intense "cooked" flavor had no appreciable effect upon the peroxidase reaction nor upon the oxidation-reduction potential of the milk. However, appreciable quantities of H_2S greatly affected the oxidation of the peroxidase reagents and markedly lowered the oxidation-reduction potential of the milk. A. H. Johnson

Cooked flavor in milk. Its source and significance. D. V. Josephson and F. J. Doan. *Milk Dealer* **29**, No. 2, 35–6, 54–62(1939).—When milk, cream, skim milk and some other dairy products are heated to a sufficiently high temp., or held for a sufficient period of time at lower temp., sulfhydryl compds. are formed from one or more of the proteins present. These sulfhydryl compds. appear to be responsible for the cooked flavor of heated milk and milk products. They are also responsible for the decrease in oxidation-reduction potential noted in heated dairy products, since they are active reducing substances. The sulfhydryl compds. are active antioxidants and appear to be responsible for the inhibition of the development of tallowy or oxidized flavor in milk heated over 170°F. In becoming oxidized (spontaneously or due to Cu contamination) the sulfhydryls apparently lose their flavor characteristic and the milk or milk product which previously exhibited a cooked flavor becomes indistinguishable from similar unheated milk. Most heated milk products do not become tallowy or oxidized until the sulfhydryls are first oxidized and the cooked flavor has disappeared. Washed-cream buttermilk in some cases appears to be an exception to this rule. The sulfhydryl substances in heated milk not only protect the milk against the development of tallowy flavor but also acts as an antioxidant toward ascorbic acid (itself an antioxidant toward tallowy flavor). Milk, cream and skim milk heated above 170°F. do not exhibit such rapid losses of ascorbic acid on storage as does raw milk or milk pasteurized in the conventional manner. While the sources of sulfhydryl compds. have not been definitely ascertained, the lactalbumin of milk seems to be the most likely ingredient responsible, with the protein of the fat globule membrane as a possible addnl. source. Some constituents of the milk serum seem to exercise a modifying role in the reaction brought about by the heat. A. H. Johnson

Curd-tension reduction of homogenized milk. A. C. Maack and P. H. Tracy. *Milk Plant Monthly* **29**, No. 1, 58(1940).—The lowered curd tension of homogenized milk is due partially to a disturbance of calcium caseinate-phospholipide complex and also to increased nos. of fat globules which tend to give weaker structure to the

curd. Under normal conditions of storage, there is no appreciable change in the curd tension of milk before it is used. A. H. Johnson

The control of sediment in homogenized milk. A. J. Hahn and P. H. Tracy. *Milk Plant Monthly* **29**, No. 1, 58(1940).—Clarification of milk after homogenization prevents sediment formation in homogenized milk. Destabilization of milk protein increases the amt. of sediment, while stabilization of protein decreases it. A. H. Johnson

Preparation and use of low-lactose milk. P. H. Tracy and W. J. Corbett. *Food Research* **4**, 493–8 (1939).—The low-lactose milk was prepd. by pptg. the colloidal casein in skim milk in such a manner that the whey and its solids can be sepd. The destabilizing agent used was Hygell, a powd. substance prepd. from the carob or locust bean. The method is detailed. By the use of this product ice cream contg. 9% normal serum solids and 4% low-lactose solids can be made that will not be sandy. Com. uses are suggested. C. R. Fellers

The "boiled-down" butter residue, the milk product richest in lecithin. W. Ritter and Ths. Nussbaumer. *Schweiz. Milchztg.* **65**, 291, 297–8(1939).—When butter is "boiled down," a residue rich in phosphatides seps. The lipides in this residue are sol. in benzene. Water is detd. by treatment of the residue at 85° in a vacuum oven. The phosphatides can be pptd. from a benzene soln. by means of acetone. Cephalin can be sepd. from lecithin by the dissolving of the phosphatides in benzene, and the pptn. of cephalin from the benzene soln. by means of ale. The phosphatides obtained by solvent extn. and subsequent volatilization of the solvent can be emulsified in water and pptd. by means of suitable quantities of acid, or metallic salts ($CaCl_2$, $MgCl_2$, $CuSO_4$, $AlCl_3$, etc.). Phosphatides comprise between 5–20% of the residue, and the quantity of, as well as the ratio between cephalin and lecithin in different samples of butter vary widely. The phosphatide content of the residue is 8–10 times as great as the phosphatide content of buttermilk. Cholesterol in the acetone filtrate, following the pptn. of phosphatides, is detd. by pptn. with digitonin. A. Leviton

Methods for disposing of dairy wastes. H. A. Trebler. *Milk Plant Monthly* **29**, No. 1, 60(1940); cf. *C. A.* **33**, 9464[2]. A. H. Johnson

A comparison of the imperviousness of commonly used paper milk containers when in contact with contained liquids. R. B. Stoltz and T. V. Armstrong. *Milk Plant Monthly* **28**, No. 12, 54–8(1939).—There is some variation in the amt. of liquid soaked up by paper milk containers. The use of 40% cream appeared to render the containers less impervious than when milk or skim milk was used. Holding at higher temp. allowed great absorption of the contained liquid. Paraffining at high temp. was not as satisfactory as paraffining at low temp., because of the greater drainage of the hot paraffin from the container. A. H. Johnson

Aluminum labels and foils weaken bottle-washing solutions. C. A. Shillinglaw and Max Levine. *Food Ind.* **12**, 41(1940).—Na aluminate is much less effective as a disinfectant than caustic soda in concns. of 1–2%. Hence, care is required to maintain alkali strength where Al caps and foils pass through the soaker washers for glassware. C. R. Fellers

Influence of dietary carotene on the carotene and vitamin A contents and the Reichert and iodine value of butterfat with special reference to seasonal variations. Sailendra Mohan Das-Gupta. *Indian J. Vet. Sci.* **9**, 249–66(1939).—Effects of feeding paddy straw, which contains little or no carotene, and grass and their mixts. were studied on 2 cows. The carotene and vitamin A contents and the Reichert values of their butterfat increased on the ingestion of grass, and were lowered on the ingestion of paddy straw. Assays of a large no. of butterfats from Vikrampur showed that the amts. of carotene, vitamin A, and the Reichert and I values were higher in the winter, when the cows feed on fresh grass, than in the autumn, when the cows live on paddy straw. The butter from an individual cow on the same diet gave similar results in spite of the adverse effects of the cold temp. and stage of lactation. Striking results were obtained by feeding a cow red palm oil, for the carotene, vitamin A and Reichert value progressively increased as the dosages of oil were increased. These results suggest that carotene may play some part in the production of more-volatile fatty acids in cow milk fat. Dorothy A. Meyer

Report of Dairy Research Institute. Starters for butter. W. J. Wiley, G. A. Cox and H. R. Whitehead. *New Zealand Dept. Sci. Ind. Research, Ann. Rept.* **13**, 20 (1939).—Addn. of about 0.5% of starter to pasteurized and chilled sweet cream and holding overnight at a low temp. before churning improves the flavor of the butter. No acidity develops in the cream under these conditions, although the resultant butter has a somewhat "brighter" flavor than if made from sweet cream alone. Appreciable biacetyl is produced in the cold cream by the action of *Str. cremoris* in the starter and not by the action of the betacocci which at higher temps. are responsible for the production of biacetyl in starters. Typical mixed cultures of *S. cremoris* and betacocci produce biacetyl rapidly during their period of logarithmic growth rate, but after reaching a peak value the production of biacetyl falls rapidly and approx. 90% is destroyed in 12 hrs. Pure cultures of betacocci, when grown in milk at 21°, do not produce appreciable quantities of biacetyl over long periods of time. **Land-cress (Coronotus didymus) taint in cream and butter.** F. H. McDowall. *Ibid.* 20.—The taint occurs during the spring months and is accentuated by the pasteurization process. Steam distn. of the plant and extn. of the distillate with petr. ether yielded 0.02–0.03% (based on the undried material) of an essential oil which had a strong odor of cress and contained 70–80% of benzyl cyanide; 1 or more S-contg. compds. was also present. Neither the oil nor artificial benzyl cyanide give the true land-cress taint when added to cream or butter. **The chemistry of incipient oxidation defects in butter.** C. R. Barnicoat and L. S. Palmer. *Ibid.* 21.—Incipient off-flavors such as "flat," "bitter," "stale storage" and "metallic" may be promoted by oxidation catalysts, including traces of Cu and Fe, but ferric Fe is inactive. These incipient oxidation changes may occur long before there is any evidence of oxidation in the butterfat and the addn. of oxidized fats or fat-sol. peroxides to butter fails to produce these types of off-flavors, but tends to promote "oxidized," "oily" or "tallowy" flavors. Oxidation of the lecithoprotein appears to be responsible for these incipient off-flavors. Most of the antioxygenic effect found in milk plasma appears to be due to the presence of sol. phosphates and citrates. The proteins also have this property to some extent and vitamins C and E seem to have antioxygenic properties. Also in *Minn. Agr. Expt. Sta., Tech. Bull.* **134**, 3–63(1939). K. D. Jacob

Effect of citric acid and sodium citrate on flavor, aroma and keeping quality of butter and ghee. Prito G. Khubchandani. *Agr. Live-Stock India* **9**, 162–6(1939).—Since Indian butter is supposed to be lacking in aroma as compared to English butter, K. studied the possibility of improving the flavor and aroma in the former by addn. of citric acid and Na citrate. The effect of such addn. in the manuf. of ghee has been especially considered. K. based his investigations upon the observations of Hammer and his associates (*C. A.* **16**, 596, 764), who reported that *S. citrovorus* and *S. paracitrovorus* ferment citric acid in milk with the production of acetylmethylcarbinol and its oxidation product biacetyl, and it is generally agreed that biacetyl is mostly responsible for producing the flavor and aroma of butter. The expt. was divided under 2 heads: addn. of citric acid and Na citrate to (1) cream and (2) starter culture. It was found that: (1) The effect of added citric acid and Na citrate in cream gives rise to increased aroma, but comparatively poorer keeping quality in butter. (2) Ghee made from such butter had a more pleasant aroma as compared with control samples. The keeping quality was improved by citric acid. (3) The use of *S. citrovorus* cultures, treated with citric acid and Na citrate 24 hrs. prior to inoculation into the cream, gave a better flavor and aroma in the resulting

butter than the use of untreated cultures. (4) The keeping quality of such butter was not affected. Edward A. Ackermann

Directions for the preparation and examination of lactic acid casein. Walter Müller and S. Lichtenberger. *Molkerei-Ztg.* (*Hildesheim*) **53**, 1362–4(1939).—See *C. A.* **34**, 534[7]. A. Leviton

The various protein nitrogen fractions in the types of cheese in most common use. Domenico Picchinenna. *Ann. chim. applicata* **29**, 452–4(1939).—The partition of N among various protein groups in several common cheeses is given. A. W. Contieri

Control work in cheese plants. Paul Ritter. *Schweiz. Milchztg.* **65**, 135–6(1939).—The following practice is recommended: reductase tests on delivered milk; rennet and indicator-paper tests on milk obtained in the stalls; identification by means of microscope of bacteria in kettle milk; acidity detns. on samples of rennet, and on whey obtained in rennet fermentation tests; acidity detns. on expressed liquor from cheese in press, and on rennet-contg. milk drawn from the kettle; pH and propionic bacteria detns. on 24-hr. old cheese. A. Leviton

A quick method for the determination of water in cottage cheese and in cream cheese. Ebinger. *Deut. Molkerei-Ztg.* **60**, 1071(1939).—Grind 5 g. of cheese with 15–20 g. of sand in a beaker. Add 10 cc. of 96% alc., and grind the mixt. until no white curd particles are visible. Evap. the alc. and water on a water bath, while stirring the contents of the beaker. After 7–8 min., the contents are dry and fine-grained. A. Leviton

Hydrogenated lard as a culinary fat. Ruth Jordan. *Purdue* (*Ind.*) *Agr. Expt. Sta., Rept. of the Director* **1937**, 64–6.—The lard was rendered from hogs fed a corn-soybean-mineral ration. The partially hydrogenated lard, the natural product and several com. shortenings were compared in pastry. Hydrogenation somewhat decreased the shortening value of the "soybean lard," but the latter had about the same shortening value as com. hydrogenated fats. The hydrogenated "soybean lard" was judged to be less intense and more desirable in flavor than the natural lard. Tests for flavor of the fats in hot baking-powder biscuits indicated a similar trend. C. R. Fellers

The hemolytic index as a criterion of the deterioration of meat. N. V. Kul'bysheva. *Voprosy Pitaniya* **7**, No. 4–5, 103–5(1938); *Khim. Referat. Zhur.* **2**, No. 4, 137–8(1939).—The method of Arutyunyan (*C. A.* **32**, 9316[4]) for judging the freshness of meat was examd. Of 20 series of expts. in only 5 did the hemolytic index coincide with the other methods for detn. of freshness (bacteriol. method of Feldman, content of NH_4 salts, Nessler no.). The hemolytic index depends on the grade and on the fat content of meat. Arutyunyan's method cannot det. the beginning of the deterioration of meat, it is not more sensitive than methods based on the chem. condition of meat proteins, and it is too complicated to justify its use. W. R. Henn

Comparative investigations on the ammonia content of meat. József Gerencsér. *Közlemények az Összehasonlító Élet- Kórtan Köréből.* **27**, 175–82(1940).—The NH_3 content was 9.17–65 mg. in 100 g. muscle in samples of beef obtained directly from slaughter houses. Beef obtained on the market contained 20.29 mg. ammonia in 100 g. (87.32 mg. in 100 g. dry matter). Pork obtained from slaughter houses contained 13.21–24 mg. ammonia in 100 g. against 21.59 mg. for pork obtained on the market. No significant differences were found in the ammonia contents of various muscles or in muscles originating of animals of various ages, sex or fat contents. The exact time of slaughtering cannot be detd. on basis of the ammonia content of the meat. Ebers' test (showing decompn. of meat) must be considered positive when the amount of ammonia exceeds 30 mg. in 100 g. muscle (or 123.4 mg. in 100 g. dry matter). The rate of the steady increase of ammonia content during storage seems to be 0.2–0.6 mg. % per hr. S. S. de Finály

Freezing makes beef tenderer. O. G. Hankins and R. L. Hiner. *Food Ind.* **12**, 49–51(1940).—Enzymes continue to act, though slowly, on meats held at freezing temps. Tenderizing may be due to both the mech. action of freezing the meat and to enzyme action. An app. measuring shearing strength is described. The tenderizing action at −23.3° was much greater than at −6.7°. However, there was no difference between −6.7° and −40° in tenderness. C. R. Fellers

Susceptibility of frozen-defrosted poultry meat to drip. C. H. Koonz and J. M. Ramsbottom. *Food Research* **4**, 485–92(1939).—Similar cooking shrinkages were obtained from unfrozen and frozen birds (−13.3 to −45.5° C.). White meat showed greater drip on defrosting than dark meat. The pH values of the dark meat were normally higher than those for the white meat. C. R. F.

Frozen storage of poultry. III. Peroxide-oxygen and free fatty acid formation. W. H. Cook and W. H. White. *Food Research* **4**, 433–40(1939).—The free fatty-acid content of poultry fat is usually low and shows no relation to storage conditions at freezing temps. The storage temp. is the most important factor in peroxide-O_2 formation in poultry fat, the amt. increasing with increase in the storage temp. At const. temp., low relative humidities accelerate peroxide-O_2 formation. This seems to be due to surface drying which exposes more of the fat to the air. Even after 25 months' storage at −13.5° the max. peroxide-O_2 titration observed was only about 8 ml. of 0.002 *N* $Na_2S_2O_3$ per g. of fat. Chicken fat is resistant to oxidation at temps. of −13.5 to −18°. C. R. F.

Increasing the storage capacity of fish with formalin ice. H. Keller. *Z. Fleisch- u. Milchhyg.* **50**, 72–3(1940).—The presence of 0.2 to 0.3% formalin (40% soln. of CH_2O) in ice used to pack fish allowed storage 5 to 6 days longer than was possible with ordinary ice. The formalin ice with the above concns. of CH_2O contributed no abnormal odor or taste to the fish. It is postulated that the psychrophile bacteria on fish produce NH_3 which reacts with CH_2O to yield innocuous hexamethylenetetramine. M. M. Piskur

Quantitative indexes of the chemical changes taking place in red fish during cold storage. N. V. Malin. *Voprosy Pitaniya* **7**, No. 4–5, 148–55(1938); *Khim. Referat. Zhur.* **2**, No. 4, 138–9(1939).—Fish fat contains a considerable amt. of easily oxidized unsatd. fats. To measure the changes taking place in fish under refrigeration, the acid no. of the Et_2O ext. is detd. as follows: Boil for 1 hr. under a reflux condenser a mixt. of 50 g. of the chopped fish with 80 cc. of ether. Decant the ether ext., to 20 cc. of the ext. add 20 cc. of C_2H_5OH, shake and titrate with a 0.1 *N* base (phenolphthalein as indicator). W. R. Henn

Blood substituted for flour in sausage manufacture. R. G. Walker. *Food Ind.* **12**, 49(1940).—Owing to the cohesive properties of blood plasma, sausages contg. blood do not burst when cooked. The blood also has a high binding value. The blood from cows contains 17.7% albumin and that of pigs 19.2%. Both red cells and plasma are used in sausages of various types in Europe. Normally 10% of blood plasma is used in sausages. The fresh blood is treated with Na citrate to prevent coagulation, strained and centrifuged to effect sepn. of red cells. C. R. Fellers

The pectic substances of plants. VI. The relation between jelly strength, viscosity and composition of various pectins. Ernest W. Bennison and Frederick W. Norris. *Biochem. J.* **33**, 1443–51(1939); cf. *C. A.* **32**, 2177[9].—There was little relation between chem. compn. and jelly strength or viscosity of pectins. In general, a high urone content connoted satisfactory jelly strength. Methoxyl content was not a criterion of jelly strength. The method of prepn. of pectins was a vital factor with respect to jelly strength and viscosity. Autoclave prepn. in the absence or presence of sucrose inhibited jelly formation. Jelly strength and viscosity of the same pectin were closely related. The power of pectin to form jellies was dependent to some extent on composition, but primarily on mol. size as indicated by viscosity. Any pretreatment which caused the polygalacturonide chain to disintegrate also caused a loss of jelly strength. E. W. Scott

[Report on] fruit cold storage. Anon. *New Zealand Dept. Sci. Ind. Research, Ann. Rept.* 13, 73–5(1939).— *Staining of pears during storage* occurred when the wrapped fruit was left in contact with ordinary corrugated pads in which Na silicate was used as the adhesive, but not by pads treated with dextrin, nor by contact with either plain white lining-paper or shredded white paper. Excellent *control of gray mold* (*Botrytis* sp.) of Winter Cole pears in storage was obtained by wrapping the fruit in Cu-treated papers. *Effect of borax on the cool-storage quality of apples.* Jonathan apples from trees sprayed with 0.1–0.2% borax solns. showed no reduction in keeping quality. Application of more than 0.5 lb. borax per tree as a top-dressing had an adverse effect. *Storage of apples on CO_2 atm.* Ballarat apples stored best in an atm. contg. CO_2 2.5 and O_2 18.5% at 39°F. A temp. of 39°F. and an atm. contg. CO_2 5 and O_2 16% were best for Washington apples. K. D. Jacob

The determination of ascorbic acid in fruit juices. Danilo Cozzi. *Ann. chim. applicata* 29, 434–42(1939).— Various methods of detg. ascorbic acid in fruit juices are described. The polarigraphic method, although giving high results, is better than the iodometric method, which gives even higher results. A. W. Contieri

The sugar and ascorbic acid contents of the juices of some Hungarian fruits. Gyula Gyenes. *Közlemények az Összehasonlító Élet- Kórtan Köréből.* 27, 200–4(1940).— Invert sugar was detd. by method of Shaffer-Hartmann (cf. *C. A.* 15, 1328), ascorbic acid by the method of Tillmans. The obtained values were: cherry 7.80% invert sugar and 0.310% ascorbic acid; mahaleb 5.25, and 0.170%; apricot 5.67, 0.045; peach 6.43, 0.015; tomato 4.02, 0.350. No connection was found between the contents of ascorbic acid and of invert sugar. S. S. de Finály

The analytical study of fruit and vegetable juices at present on the (French) market. A. Guillaume and Mlle. M. Michon. *Ann. fals.* 32, 301–19(1939).— Analyses are given of a no. of com. samples of red and white grape juices, apple, orange, grapefruit, mandarin, strawberry, gooseberry, cherry, raspberry, black currant, loganberry and tomato juices, and of corresponding lab.-prepd. juices. Analysis comprised detn. of d., acidity, alc., total solids, ash, sugars, total N, pectins and viscosity (methods used are described). The results are discussed on the basis of the method of interpretation described by Pien and Meinrath (*C. A.* 32, 7593[8]) showing that a no. of the com. samples had been "cut" with a dil. sugar soln. Generalization of the method would necessitate extensive work to establish reliable data on the compn. of pure juices from different varieties of fruit in different regions. A. Papineau-Couture

Suitability of the iodometric method for sulfurous acid in the examination of sultanas, fruit jellies and jams. Béla Mayer and László Heltai. *Mezőgazdasági Kutatások* 12, 209–16(1939).—As the gravimetric SO_2 detn. made in a CO_2 current is not suited for large scale examns. of samples, comparison was made to prove the suitability of the German official method prescribed for SO_2 detns. in wine or must. For sultanas the gravimetric method without a CO_2 current gives low values; the titrimetric detn. with 0.02 *N* iodine soln. gave high values. The iodometric method seems suitable for preliminary investigation to make possible a selection of samples. Iodometric detn. cannot be used for fruit jams (very high values). For SO_2 content (both free and total) of fruit jellies the iodometric gives reliable results, equal to those obtained by the gravimetric method. S. S. de Finály

Effect of sulfur fumigation on quality of rice. A. Sreenivasan. *Agr. Live-stock India* 9, 149–54(1939).— Shipments of parboiled rice are often subjected to S fumigation prior to their being imported. S. studied the extent to which such treatment affects the quality of the rice. The quantities of SO_2 retained by the rice grains after fumigation under different conditions were considered a good measure of this extent. A weighed quantity of the SO_2-treated rice was crushed, extd. with successive small quantities of water and filtered. The SO_2 in the filtrate was estd. by direct titration with standard 0.01 *N* I_2 soln. and by pptn. with $BaCl_2$, after initial oxidation with H_2O_2. Based on his findings, S. draws the following general conclusions: Rice grains exposed to a 3% concn. of SO_2 fumes inside a wide-mouthed bottle absorb appreciable quantities of the gas even at the end of 5 min. The quantity of the gas absorbed increases with the humidity of the atm. and with decreased air supply. Long exposure or drying in a current of air or in the sun results in partial removal of the gas; a further small quantity is lost during cooking. But a small amt. is always held tenaciously by the grain and it imparts a definite flat and acidic taste and odor to the cooked product. SO_2-treated rice cooks rapidly and to a squashy consistency owing to partial hydrolysis of the starch during cooking in the somewhat acid medium. Such rice also digests more slowly than untreated rice. Freshly fumigated rice is yellowish in color, though the color becomes very much lighter on exposure. The cooked product, however, is perfectly white. The conditions existing in shiploads and in large-scale operations are different, so that in practice the extent to which S fumigation affects the quality of the rice may not be as pronounced as in the expts. performed. Further expts., on a large scale, are therefore desirable. E. A. A.

Carotene (vitamin A) content of fresh and frosted peas. C. R. Stimson, Donald K. Tressler and L. A. Maynard. *Food Research* 4, 475–82(1939).—Fresh frozen and fresh peas have approx. the same carotene content. About 25% of the carotene is lost during 11 months' storage at −17.8°. Fresh peas contain approx. 6.1 I. U. per g. of vitamin A. A ratio of vitamin A to carotene of 1.5 was obtained. C. R. Fellers

Vitamin A values of sweet potatoes, turnips and carrots. Florence L. MacLeod and Evelyn Utley. *Tenn. Agr. Expt. Sta., 15th Ann. Rept.* 1937, 34–6(1938); cf. *C. A.* 30, 1451[6]; 31, 8735[8].—Cooked sweet potatoes are about twice as rich in vitamin A, as detd. by the animal bioassay method, as raw sweet potatoes. When corrected for moisture content the increase due to cooking is 36%. The vitamin A value also increases progressively during storage. The yellow turnip is a poor source of vitamin A as even 6 g. fed daily to rats depleted of vitamin A, made no wt. gains. Rutabagas contain considerably more vitamin A than turnips but much less than sweet potatoes. The Chantenay variety of carrot contained 40 Sherman units per g. in the raw state and about 60 units after cooking. Storage of carrots did not increase their vitamin A content. C. R. Fellers

Simulation, by chemical agents, of cooking potato tissue. Catherine J. Personius and Paul F. Sharp. *Food Research* 4, 469–73(1939); cf. *C. A.* 33, 7916[1,4].— The starch of potato tissue can be gelatinized by 40% chloral hydrate, 40% CHOH, 2 *N* soln. of Na salicylate and by a soln. of NH_4CNS prepd. by adding 40 g. of NH_4CNS to 200 ml. of water and 50 ml. of 95% EtOH. By treatment with $(NH_4)_2C_2O_4$, cell adhesion can be so reduced that it is characteristic of cooked tissue. It is possible to simulate cooking by first treating potato tissue with a cold gelatinizing agent and subsequently with $(NH_4)_2C_2O_4$. The texture of the potato appears to be the same whether cooking is simulated by chem. means or is accomplished by heat. Two changes are necessary for converting raw potato tissue into cooked tissue: (1) gelatinization of the starch and (2) a marked decrease in the cell adhesion of the tissue. These factors do not explain the differences between mealy and soggy potatoes. C. R. Fellers

The relation of the calcium ion to the sloughing of potatoes. W. E. Pyke and Gestur Johnson. *Am. Potato J.* 17, 1–9(1940).—Satisfactory control of sloughing of potatoes is obtained when approx. 12.5% of the salt used in the water in which the tubers are boiled is a sol. Ca salt. The total salinity of the cooking water should be about 1%. $CaCl_2$ gives good results but is too hygroscopic for home use. A satd. soln. of $CaSO_4$, salted in the usual manner, gives excellent control of sloughing. Ca sulfamate, which is readily sol., nonpoisonous and nonhygroscopic, is now available at moderate prices and is

very satisfactory. Also in *Colo. Agr. Expt. Sta., Farm. Bull. Quart.* 2, 11–12(1940). K. D. Jacob

How to use dextrose in canning. E. W. Eickelberg. *Food Ind.* 12, 33–5, 50–1(1940).—In the sirups for canning most fruits and such vegetables as beets, tomatoes, peas and rhubarb, dextrose can be advantageously used in place of a portion of the sucrose. While 100% dextrose can be used in citrus fruits and juices, about 25–35% is most desirable for other products such as berries, peaches, pears, cherries and prunes. Dextrose improves the flavor in many fruits because the natural flavor of the fruit is not masked. While at lower concns. dextrose sirups are only 66–75% as sweet as sucrose sirups of the same concn., at higher sirup concns. there is less difference in sweetness. Dextrose increases "shelf life" of products in which it is used. This is particularly true of canned citrus fruits and juices. The reducing properties of the dextrose retards deterioration of flavor. C. R. Fellers

Appropriate means for detecting artificial honey. J. Grossfeld. *Z. Untersuch. Lebensm.* 78, 380–5(1939).—A scheme for analysis of honey is given. In some cases adulteration with artificially inverted sugar can be detected by the Fiehe method (*C. A.* 3, 83). Most artificial honeys contain sulfate. Analysis for this radical can serve for detecting adulteration of flower honey, but, is not recommended for all honeys for sulfate is a natural constituent of leaf honey. Adulteration with starch sirup can be detected as follows: Dissolve 10 g. of sample in water, add 1 cc. of $K_4Fe(CN)_6$ and ZnOAc clarifying soln. and make to 100 cc. Filter 1 cc. in a test tube, add 1 drop of 25% HCl and 10 cc. of 95% alc., shake and observe against a dark background immediately and after 2 hrs. The presence of 1% starch sirup will cause an opalescence to develop after mixing; with 0.5% starch sirup an opalescence develops in 2 hrs. The sensitivity of the test can be improved with the use of iso-PrOH or PrOH. However, these modifications may cause a turbidity with leaf honey. M. M. Piskur

Experimental work on lactic acid in preserving pickles and pickle products. I. Rate of penetration of acetic acid and lactic acids in pickles. Frederick W. Fabian and C. K. Wadsworth. *Food Research* 4, 499–509(1939); cf. *C. A.* 33, 9473[2].—In the freshening of salted pickles NaCl is extd. to the greatest extent during the 1st hour. Little NaCl is removed after 24 hrs. NaCl is removed from small pickles much more quickly than from large ones. AcOH penetrates pickles more rapidly than lactic acid. The rate of acid penetration is greatest during the first 24 hrs. and equil. is reached after about 40 hrs. Not only is the concn. of the acid important but also the ratio of wt. of pickles to wt. of acid present. **II. Preserving value of acetic acid and lactic acids in the presence of sucrose.** *Ibid.* 511–19.—The pH value of AcOH and lactic acids is not a reliable indicator of the preserving power of the acids. AcOH possesses much higher preserving value in pickle products than lactic acid. In mixts. of the 2 acids, the preserving power was usually in proportion to the AcOH present regardless of the percentage of sugar present until the sugar concn. reached 22° Baumé. Lower concns. of sugar affected the preserving power of the acids but little. An acidity of not less than 2.0% AcOH or a combination of AcOH and lactic acid, where the latter makes up from 20–40% of the total acidity calcd. as AcOH, is recommended for preserving pickles or pickle products. **III. Use of lactic acid in pickles and related products.** *Ibid.* 521–9; cf. *Fruit Products J.* 16, 209–211, 214, 217, 240–3(1937).—Lactic acid is unsuitable for the manuf. of sour pickles both from the point of view of flavor and preserving properties. Lactic acid alone is likewise unsuitable for sweetened pickle products. When used with AcOH in ratios of 0.4:1.6 and 0.2:1.8, the flavor was improved. A combination of AcOH and lactic acid improved the flavor of dill pickles. Approx. 5 times as much AcOH should be used as lactic acid. C. R. Fellers

New method for preventing oil separation. C. W. Lenth. *Food Ind.* 11, 678–9(1939).—The addn. of a small amt. of glycerol to peanut butter prevents sepn. of oil and makes finer grinding of peanut solids practicable. From 1.5 to 2.0% of glycerol usually gives the desired results. The taste and keeping quality are unaffected. C. R. Fellers

The antiseptic action of phenols, phenolcarboxylic acids and the esters of lichen substances. VI. The antiseptic action of orcinoldicarboxylic ester on soy sauce. Hukuziro Huzikawa. *J. Pharm. Soc. Japan* 59, 615–16 (in German, 239–40)(1939); cf. *C. A.* 33, 9547[8].—4-Methoxy-1,3-orcinoldicarboxylic acid, 3-mono-Me ester, di-Me 4-methoxy-1,3-orcinoldicarboxylate, 1,3-orcinoldicarboxylic acid, 3-mono-Me ester, di-Me 1,3-orcinoldicarboxylate and di-Et 1,3-orcinoldicarboxylate were all inactive at the concn. ranging from 0.015 to 0.03%. **VII. The antiseptic action of the compounds of the olivetol series on soy sauce.** *Ibid.* 617–18(in German, 240–1).—Olivetol, 2,5-dihydroxyvalerophenone and Me olivetolcarboxylate showed an antiseptic action, while *p*-Me ether of olivetolcarboxylic acid and di-Me ether of olivetolcarboxylic acid did not show antiseptic action. F. I. Nakamura

Determination of the crude fiber in coffee substitutes and coffee supplements. H. Thaler, H. Beitter and Th. v. Spiess. *Z. Untersuch. Lebensm.* 78, 387–92(1939).—The caramelization of coffee supplements and substitutes, i. e., chicory, rye, barley, etc., during roasting causes an increase in the results obtained on analysis for crude fiber. The crude-fiber results on a chicory subjected to various degrees of roasting varied from 6.21 to 81.7% when detd. by the Weender method and from 6.64 to 9.71 by the Scharrer and Kürscher method (*C. A.* 25, 5718[7]). The latter method is considered more suitable. M. M. P.

The fermentation process in tea manufacture. IV. Tea tannin and its fermentation products. C. J. Harrison and E. A. Houghton Roberts. *Biochem. J.* 33, 1408–20(1939); cf. *C. A.* 33, 7917[8].—The prepn. and properties of tea tannin were described. Tea tannin from the green leaf appeared to be a mixt. of *l*-epicatechin, gallocatechin and their simpler condensation products. The galloyl ester of epicatechin was present only in some types of leaf. Tannins in made tea were much more complex. In fermentation the catechol or pyrogallol nucleus only became oxidized and the product then underwent extensive condensations. At 40° the condensation was faster than the enzymic processes and tea manufd. under such conditions contained more highly condensed tannins. Strongly cationoid polyphenols such as tea tannins were readily oxidized by peroxidase while anionoid gallic acid was oxidized slowly. E. W. Scott

Ensilage. G. Luchetti. *Ann. facoltà agrar. univ. Pisa* [N. S. 3rd] 2, 46–60(1939).—The addn. of NaCl (0.1%) to tightly closed silos favors the development of free acidity. Addn. of H_2SO_4 (0.14% of 47°Bé. acid) to the compressed product increases free volatile acids. The max. of milk-modifying microörganisms in the feed was found in the closed silages with NaCl, while the max. of peptonizing microörganisms was found in the silages treated with H_2SO_4; gas-forming microörganisms were found in both cases. G. A. Bravo

The value of grass and grass drying. M. W. Goodwin and G. L. Schuster. *Del. Agr. Expt. Sta., Bull.* 214, 21(1938), *Ann. Rept.* 1938.—The protein content of grass clipped and dried in a Billingham type dryer when 5–7 in. in height is 15–24% as compared with 7% for the 1st crop of hay as normally harvested. C. R. Fellers

Calcium lactate as a mineral supplement for bacon pigs. H. D. Meberg. *Meldinger Norges Landbrukshögskole* 19, 294–306(1939).—Feeding expts. on pigs with Ca lactate and $CaCO_3$ as a source of Ca showed equally good results. M. recommends $CaCO_3$ since it is considerably cheaper than Ca lactate, as a mineral supplement for domestic animals. V. Aschehoug

Dairy cattle feeding investigations. Carotene content of pasture plants. H. W. Cave and F. W. Atkeson. *Kansas Agr. Expt. Sta., 9th Biennial Rept.* 1938, 80–2; cf. *C. A.* 33, 5043[6].—Carotene detns. were made on 13 pasture plants at different stages of growth. There was a marked reduction of carotene during the hot months. The carotene increased again after the fall rains. Studies

were made on the utilization of the carotene in green rye by dairy cows when the daily intake was excessive. Of the carotene ingested daily, an av. of 0.086% was recovered daily as carotene in the butter and an av. of 0.154% as vitamin A, or a total of 0.24% in terms of international units. When the carotene intake is excessive the ratio of carotene to vitamin A in the butter of Holstein and Ayrshire cows becomes rather const. at about 1:2. C. R. Fellers

The ascorbic acid contents of some Hungarian feeds. Ferenc Tompa. *Közlemények az Összehasonlító Élet-Kórtan Köréből.* **27**, 195–200(1940).—Ascorbic acid contents found by the method of Tillmans were: alfalfa hay 0.01689, meadow hay 0.01610, red-clover hay 0.01323, sainfoin hay 0.01134, vetch hay 0.01024, barley straw 0.01075, wheat straw 0.00628, rye straw 0.00000, oat straw 0.01539, corn ears and stem 0.01131, barley 0.00071, wheat 0.00058, rye 0.00066, corn 0.00033, oats 0.00205%. Ascorbic acid contents 3 days and 6 days, resp., after germination were: barley 0.00931–0.02120, wheat 0.00821–0.02367, rye 0.03723–0.04398, corn 0.01276–0.02410 and oats 0.02460–0.03023%. The ascorbic acid content was about the same for seed germinated in darkness as for seed kept in sunlight. Feed exts. lost their reducing power in alk. medium within 20 min.; exts. of cereal germs, after 30 min. S. S. de Finály

Feeding cows rations which contain adequate amounts of carotene. J. L. Henderson. *Milk Plant Monthly* **28**, No. 12, 26–7(1939).—Rations which are high in carotene content decrease the incidence of spontaneously developed oxidized flavor in milk and render the milk less susceptible to metal-induced oxidized flavor. Rancid flavors are also reduced by green feed and this effect is attributed to the carotene content. Carotene concentrate, carrots, various green feeds and alfalfa preserved in such a way as to preserve its green color have been used successfully for this purpose. Such feed not only prevents the development of off-flavors in the milk but also supplies better nutrition to the cow and operates to produce milk of higher vitamin content. A. H. Johnson

Feeding vitamin A to cows. W. H. Martin. *Milk Plant Monthly* **28**, No. 12, 42(1939).—Feeding of vitamin A at 30,000, 90,000 or 300,000 unit levels for 10 to 20 days to cows on dry rations failed to produce any marked improvement in the flavor score of fresh or 3 day old milk. However, it reduced the incidence of oxidized flavor and improved the score of copper-treated milk. Feeding of 1/6 to 1/3 g. daily of carotene for 10 days immediately after vitamin A feeding caused some improvement in the flavor scores of stored milk and reduced the intensity of oxidized flavor in copper-treated milk. The effect of feeding vitamin A on the color of milk was variable. A. H. Johnson

Stability of carotene in dehydrated alfalfa and oat-plant meal. L. F. Payne and D. C. Warren. *Kansas Agr. Expt. Sta., 9th Biennial Rept.* **1938**, 93; cf. *C. A.* **25**, 4206.—After 1 year's storage in a dry warm place 100-lb. bags of alfalfa leaf meal and oat-plant meal contained 81,600 and 63,600 I. U. vitamin A per lb., resp. The loss of carotene content of the 2 samples for the year was 66.4 and 79.4%, resp. C. R. Fellers

Sprouted fodder and germinated grain in stock feeding. I. Leitch. *Imp. Bur. Animal Nutrition, Tech. Commun.* No. **11**, 63 pp.(1939).—Published data on the changes in compn. of the seed during germination and growth of the seedling and on feeding expts. with grain prepd. by conf. methods with culture solns. and with grain germinated under simpler conditions with water are presented and summarized. The evidence is neg. as regards any special value of sprouted fodder for milk production, growth of calves, or pig fattening, but at 1 center sprouted maize has given excellent results with fattening bullocks. There is no conclusive evidence that germinated oats have any beneficial effect on reproduction in farm animals. The use of germinated grain in rations not contg. fresh green food has been found to increase egg production and the fertility and hatchability of eggs. Fifty-five references. K. D. Jacob

Value of orange pulp for livestock feeding. W. M. Cory. *Calif. Citrograph* **25**, 32(1939).—Fresh oranges and the dried orange pulp have a definite value for livestock feeding. The dried pulp has an av. of 6 lbs. of digestible protein and 72.2 lbs. of digestible carbohydrates in 100 lbs. of feed. Fresh oranges have about one tenth this feeding value. J. R. Adams

The optimum of crude fiber and protein in cattle feeds. Joel Axelsson. *Kgl. Lantbruksakad. Tid.* **78**, 323–34 (1939); cf. *C. A.* **32**, 4634[5]; **33**, 8716[5], 8726[2,3], 8848[2].—The results of 71 expts. by Kellner (K. and Köhler, *Landw. Versuchs-Sta.* **53** (1900); Fingerling, *et al.*, *Ibid.* **114**, 1; **116**, 1(1933); *C. A.* **29**, 496[5]; **31**, 3530[7]; **32**, 6698[6]) form the basis of this study. In fattening oxen the utilization of the food is at a max. when the feed contains 20–21% crude fiber; it becomes perceptibly poorer if the crude fiber content is below 18% or above 23%. About 10% of the stored energy consists of protein energy. Protein synthesis occurs simultaneously with fat formation. Protein tissue is necessary to store fat. The energy exchange is optimal if the protein content of the feed is 10–18% of the digestible org. matter. Optimal contents of crude fiber and protein in a feed are necessary for the best possible nutritive exchange. The digestible nutrients of 71 feeds, in which the crude fiber content of the dry matter varied between 14 and 32%, gave the same value as the av. found by K. for the pure foods; but 34 feeds with optimal contents of crude fiber and protein gave a higher value equal to that found by K. for pure starch. The varying exchange found by K. for different foods is attributed to his failure to use optimal amts. of crude fiber and, especially, of protein. The evaluation of feeds must be based on the metabolizable rather than the net energy value. Ruth Berggren

Liverseege's Adulteration and Analysis of Foods and Drugs. London: J. and A. Churchill Ltd. 36s.

Flavoring solutions for foods, tobacco, etc. Frits E. Stockelbach. U. S. 2,180,932, Nov. 21. Mono- or diethyl glycerol is used as a solvent for flavoring substances such as lemon oil, orange oil and vanillin or various mixed esters such as those constituting imitation raspberry or banana flavors.

Concentrated milk. Fernand Sornet and Gabriel Etienne. Fr. 841,130, May 10, 1939. See Brit. 495,746 (*C. A.* **33**, 3480[4]).

Heat-exchange apparatus suitable for treating milk. Harvey Feldmeier (to Cherry-Burrell Corp.). U. S. reissue 21,270, Nov. 21. A reissue of original patent No. 1,840,573 (*C. A.* **26**, 1678[2]).

Soluble dried solids of milk. Harold K. Salzberg (to Borden Co.). U. S. 2,181,003, Nov. 21. See Brit. 503,811 (*C. A.* **33**, 7426[3]).

Centrifugal apparatus suitable for homogenizing butter with milk in producing cream. Howard L. Saylor (to Homogenizer Corp., Ltd.). U. S. 2,180,301, Nov. 14. Various structural and operative details.

Curing meat. Walter M. Urbain (to Industrial Patents Corp.). U. S. 2,180,750, Nov. 21. A curing paste suitable for use on fresh pork bellies, etc., is formed of salts such as NaCl, $NaNO_3$ and $NaNO_2$ and a starch-contg. material such as a tapioca paste which may be prepd. by cooking tapioca flour with water contg. H_3PO_4.

Pickling meat. August Nietiedt. U. S. 2,180,165, Nov. 14. Fresh meats such as hams and beef are permeated with a soln. of NaCl and KNO_3 and then wrapped in a narrow meshed cloth, subjected to centrifugal action to remove excess treating soln. (which is recovered for further use) and then subjected directly to a smoking process.

Iodized vitaminic fish oils. Henry Brinton. U. S. 2,179,917, Nov. 14. A product suitable for addn. to poultry rations or other use as a food ingredient is prepd. by adding I to an oil such as sardine oil or burbot oil and dispersing the oil as by emulsification with dried milk, or flour or starch and water, under conditions maintaining the vitaminic properties of the oil substantially unimpaired.

Coloring citrus fruits. Longfield Longfield-Smith (to Mrs. B. C. Skinner). U. S. 2,179,762, Nov. 14. A coloring process involves providing as a dye concentrate soln.: a mixt. of a soln. of an oil dye in a water-insol. solvent selected from the following group: $CHCl_3$, CCl_4, $C_2H_4Cl_2$, $C_2H_2Cl_4$, $C_2H_3Cl_3$, C_2CHCl_5, $C_2H_2Cl_2$, C_2HCl_5, perchloroethylene and $C_6H_4Cl_2$, with a water-sol. solvent selected from the following group: butanol, ethers of monoethylene glycol, ethers of diethylene glycol, cyclohexanol, diacetone alc., EtOH, PrOH the mixed oil-dye solns. being dissolved in a soap soln., emulsifying this dye concentrate soln. with water, and exposing the citrus fruit surfaces in contact with the emulsion at a temp. of about 32–38° until the desired degree of color has been imparted to the fruit.

Fumigant suitable for treating fruits, etc. John D. Maxey (to Carbide and Carbon Chemicals Corp.). U. S. 2,180,744, Nov. 21. See Can. 385,741 (*C. A.* **34**, 1412[5]).

13—CHEMICAL INDUSTRY AND MISCELLANEOUS INDUSTRIAL PRODUCTS

(PLASTICS, RESINOIDS, INSULATORS, ADHESIVES, ETC.)

HERMAN A. BRUSON

Recent developments in chemical technology. Fritz ter Meer. *Chem. Fabrik* **1940**, 1–3; cf. *C. A.* **33**, 5085[8].
J. H. Moore

Visualizing the American chemical industry. S. Isermann. *Progressive Perfumery & Cosmetics* **1938**, 61–3.—This industry represents almost one-fifth of all the manufg. enterprises in the U. S.
Leopold Scheflan

New industrial applications for metallic naphthenates. John S. Trevor. *Chem. Industries* **45**, 661(1939).
E. H.

Review: Gas warfare and air defense. R. v. Heuss. *Jahreskurse artzl. Fortbild.* **30**, No. 9, 24–34(1939).
Ruth Berggren

Vesicants [in warfare]. D. H. Wester. *Pharm. Weekblad* **76**, 1317–24, 1342–62, 1378–90, 1410–28(1939).—A review.
G. G.

What the fireman needs as gas defense. Carbonnier. *Fire* **32**, 146–7(1940).—A description of the essential properties of the ideal type of self-contained and self-controlled breathing app. for fire-fighting purposes.
L. S.

Benzine poisoning. H. H. Jansen. *Führer-Wielands Sammlung von Vergiftungsfällen* **9**, No. 10, 133–50(1938); *Rev. Current Lit. Paint, Colour, Varnish & Allied Ind.* **12**, 471(1939).—Three cases of epilepsy are attributed to acute benzine poisoning.
George Ayers

Researches on bone marrow occupational lead poisoning. G. Montegrosso. *Medicina Lavoro* **30**, No. 1, 1–8(1939); *Rev. Current Lit. Paint, Colour, Varnish & Allied Ind.* **12**, 472(1939).
George Ayers

Injury by Asplit. E. Schrader and W. Rösgen. *Münch. med. Wochschr.* **86**, 1239–41(1939).—Among men working with this product (a mixt. of phenol-formaldehyde resin, quartz dust, *p*-toluenesulfonyl chloride and kaolin, used for making containers for acids and alkalies) different symptoms have been observed. Irritation of the skin, especially itchy eruption, irritation of the mucous membranes of the respiratory tract, gastro-intestinal disturbances, disorders of the nervous system, ranging from slight feelings of illness to stupor, unconsciousness and epileptic convulsions, occurred. The workers most often affected were those who heated the substance to 140°F.
Maurice M. Rath

Toxicity of coal-tar naphtha distillates. H. Taylor. *Chemistry & Industry* **1939**, 1078–80.—Coal-tar naphtha distillates are used for the fumigation of houses against the bedbug. Distillates b. 160–90°, were shown by expts. on rats to have definite narcotic action at concns. greater than 0.10% by vol.; in one expt. a single exposure to 0.16% caused the death of all exptl. rats in less than 6 hrs. These results are contrary to those reported in *C. A.* **32**, 3028[5].
E. G. Meiter

Silicosis and allied disorders. History and industrial importance. H. B. Meller, *et al. Air Hyg. Foundation America, Inc., Med. Ser., Bull.* No. 1, 178 pp.(1937).—The occurrence pathology, diagnosis and prevention of silicosis are discussed. Research projects are outlined.
Leopold Scheflan

The prevention of silicosis; experimental investigations on the action of certain nonsiliceous dusts and silica in the origin and development of silicosis. Carl Naeslund. *J. Ind. Hyg. Toxicol.* **22**, 1–30(1940).—Rabbits and guinea pigs were exposed to quartz, colloidal and amorphous silica, leptite, cement and glass dusts. Coal, soda, $Ca(OH)_2$, $Al(OH)_3$, Al, iron oxides, and MgO were mixed with silica dusts and the effects of mixed dusts were studied. Al and $Al(OH)_3$ retarded the rise of silicosis and inhibited fibrosis. Alk. dusts increased the irritation of silica.
A. L. Elder

Poisoning from thallium dust. Wilhelm Schwarte. *Münch. med. Wochschr.* **86**, 1299–1300(1939).—A typical case of Tl poisoning is reported, caused by inhaling a considerable amt. of Tl dust during cleaning of a draw in which grain impregnated with Tl acetate had been placed.
Maurice M. Rath

The percentage of particles of different sizes removed from dust-laden air by breathing. A. M. van Wijk and H. S. Patterson. *J. Ind. Hyg. Toxicol.* **22**, 31–5(1940).—About 25% of particles of size 0.2 μ and about 80% of size 2 μ are removed. The percentage increases slowly until at a size of 5 μ about 95% of the particles are removed. A. L. Elder 1

Dust sampling—a device for adjusting the nozzle distance in the Devers circular konimeter. Walter S. Weeks. *Can. Mining J.* **61**, 29(1940).—The modification suggested for the Devers circular konimeter which is quite widely used for dust sampling in a no. of Canadian mines consists of replacing the springs by a circular fiber disk which is pressed against the glass by a screw bearing on the center of the disk. Details are shown by sketches. W. H. B. 2

The van der Grinten dust-protective hood and clothing. H. Hebestreit. *Zentr. Gewerbehyg. Unfallverhüt.* **24**, 55–6 (1937); *U. S. Pub. Health Eng. Abstracts* **18**, IHS, 1–2 (Jan. 15, 1938); cf. *C. A.* **33**, 6600⁹.—This type of hood and clothing is entirely effective in preventing finely ground color powders reaching the skin or face of the workers. It is made of batiste material which is rendered air and watertight by treatment with varnish or rubber. The hood is light, covers the whole head and has a large celluloid window in order not to limit the vision. C. R. F. 3

Furfural plastics—a survey of developments in recent years. L. Light. *Brit. Plastics* **11**, 314–15(1939).—A review with 15 references. E. H. 4

Plastics progress during 1939. Molding presses. George K. Scribner. *Modern Plastics* **17**, 43–4(1940). **Coatings.** W. T. Pearce. *Ibid.* 44–5.—8 references. **Cellulose esters.** Harold K. Haviland. *Ibid.* 45 6; cf. *C. A.* **34**, 190⁸.—17 references. **Cellulose ethers.** S. L. Bass and A. E. Young. *Ibid.* 46–8; cf. *C. A.* **33**, 5539⁷.—28 references. **Laminates.** G. E. Landt. *Ibid.* 48. **Phenolic resins.** L. M. Debing. *Ibid.* 48–52.—32 references. **Thermoplastic resins.** H. S. Bunn. *Ibid.* 52–6.—55 references. **Urea resins.** M. H. Bigelow. *Ibid.* 56–8.—48 references. E. H. 5

New foliated plastic, "drevolit." Ya. M. Lukomskiĭ and O. M. Klimova. *Lesokhim. Prom.* **1938**, Nos. 3–4, 11–15; *Khim. Referat. Zhur.* **2**, No. 4, 130(1939).—Wood was satd. with an alc. soln. or with an aq. suspension of resin obtained by condensation of phenol with lignin, together with urotropine in the amt. of 14% of the resin. "Drevolit," which differs from "lignofol" by the new type of org. binding substance (phenol-lignin resin), possesses similar mech. and dielec. properties. Its water resistance is slightly lower, especially when prepd. from a water suspension of resin. Its possible uses in industry are described. W. R. Henn 6

Can protein plastics be made elastic? Johann W. Eggert. *Gelatine, Leim, Klebstoffe* **7**, 171–3(1939).—Three methods for increasing elasticity of protein plastics are: (1) mech. working to produce long micelles, (2) addn. of glycerol in comparatively large amts. and (3) partial soln. of the protein with nonaq. compds. of which salicylic acid is the best example. The 1st and 3rd methods are recommended. Don Brouse 7

Use of ebonite as a plastic. André Sorin. *Rev. gén. mat. plastiques* **15**, 236–8(1939).—Practical operating directions. A. Papineau-Couture 8

Effect of nonvolatile material on solvent balance. Plasticizers. John B. Dorsch. *Ind. Eng. Chem.* **32**, 279–82 (1940); cf. *C. A.* **32**, 3640⁸.—Continued study of the evapn. of solvent mixts. from films of nitrocellulose-estergum lacquers showed that relative humidity, temp., length of period for total evapn. and age of the lacquer had little effect upon the solvent balance. The age of the nitrocellulose, etc., may, however, cause variation. Both the solvent type of plasticizer (dibutyl phthalate) and the nonsolvent (blown castor oil) increased the hydrocarbon retention of the films. Arnold M. Collins 9

Mixed plastics made of synthetic resins and proteins. Albert Lefèvre. *Rev. gén. mat. plastiques* **15**, 231–5(1939).—A brief review of a no. of Fr. pats. relating to processes providing for the stabilization of synthetic-resin (especially urea-CH_2O) plastics by the addn. of relatively small amts. of proteinic colloids, and processes relating to the modification (stabilization, plastification) of protein plastics by the addn. of synthetic resins. A. Papineau-Couture 1

Thermoplastic resins obtained from depolymerized rubber. J. Grange-Neyrand. *Rev. gén. mat. plastiques* **15**, 228–31, 260–4(1939).—A description (based on pat. specifications) of the prepn. of depolymerized rubber by the use of chlorostannic acid ($SnCl_4.2HCl.6H_2O$), of its general properties, and of its use for the production of thermoplastic resins and of artificial pearls and mother-of-pearl. A. Papineau-Couture 2

The coumarone and indene resins industry. Emile Chomard. *Rev. gén. mat. plastiques* **15**, 200–5, 239–40, 258–60, 285–7(1939).—A brief review of the general properties of coumarone and of indene, of their polymerization, of the com. prepn. of coumarone and indene resins, of their properties and of their applications in varnishes (giving typical formulas for quick-, medium- and slow-drying varnishes), linoleum, lining materials, etc. A. P.-C. 3

Progress in alkyd resins. A. G. Hovey. *Modern Plastics* **16**, 80, 82, 86, 88(1938). E. J. C.

Some aspects of the synthesis and use of glycerophthalic resins. Carlo Stresino. *Atti X° congr. intern. chim.* **4**, 268–74(1939).—See *C. A.* **33**, 2674. J. E. D.

Urea-resin finishes—their function and characteristics. C. A. Knauss. *Can. Chem. Process Inds.* **24**, 9–10(1940).—Urea-CH_2O resins are characterized by pale color and relatively low-temp. baking schedules. In an aq. medium, the reactions of urea and CH_2O are dependent upon the catalyst used, the mol. ratio of the components and the temp. of reaction. The usual reaction consists of 1 mol. of urea and 2 mols. of CH_2O, which form dimethylolurea which then combines, either by condensation or polymerization, to form a complex compd. contg. a no. of cross linkages which account for the gelation of the resin. The properties and types of solns. are discussed. Urea-CH_2O resins are used in 4 types of products: (1) high-baking enamels, (2) low-baking enamels, (3) air-drying enamels and (4) emulsions. W. H. Boynton 4

Fatty-acyl-modified resins—dicyclopentadiene, coumarone and indene types. A. W. Ralston, R. J. Vander Wal, S. T. Bauer and E. W. Segebrecht. *Ind. Eng. Chem.* **32**, 99–101(1940).—High-mol. wt. acyl groups have been introduced by a Friedel-Craft reaction between fractions contg. resin forming substances and fatty acid chlorides, the products being mixts. of monomers, dimers, trimers, tetramers or higher polymers varying from viscous liquids to solids. The starting materials were (*a*) the crude solvent naphthas contg. as a major constituent coumarone (I), indene (II) or dicyclopentadiene (III), resp., together with lesser quantities of the other 2, and (*b*) a commercial I-resin produced by the polymerization of a I-contg. fraction. Stearoylation of the I-fraction using 100, 67, 33 and 10% of an equimol. proportion of stearoyl chloride, resp., resulted in a series of soft solids; except in the 1st 2 cases, heating at 100° for 65 hrs. gave hard resins, decidedly less brittle than the heat-treated unmodified sample. Mol. wt. detns. by the cryoscopic method in benzene indicate the products to be essentially mixts. of dimers and trimers; the mol. wt. of the product from equimol. wt. of stearoyl chloride indicates only a small amt. of polymerization. Acetylation of I fraction with 10, 33 and 67% of an equimol. proportion of oleoyl chloride gave soft solids which polymerized further to hard resins when baked at 100° for 65 hrs.; the mol. wt. of the 67% product corresponds closely to that of an acylated dimer. Acylation of I fraction with linolenoyl chloride resulted in products ranging from very viscous liquids to soft solids, all of which formed hard resins when heated at 100° for several hrs. and some of which possessed the property of air drying; the 10 and 100% products had mol. wts. of 335.3 and 506.0, resp., the former increasing to 564.2 upon baking at 100° for 40 hrs. The products from II fraction and 10, 33, 67 and 100% equimol. proportions of stearoyl chloride were highly viscous liquids or soft solids; when heated at 100° for several hrs. the 10 and 33% products polymerized further to hard resins, while the others were not affected by this treatment; the mol. wt. of the 67% 5

product indicates that it contains a considerable amt. of the stearoylated dimers. Acylation of II fraction with oleyl and linolenoyl chlorides resulted in all cases in highly viscous oils which, when heated for several hrs. at 100°, gave hard resins; the 33, 67 and 100% products from linolenoyl chloride dried upon exposure to atm. conditions; the 100% linolenoyl sample had a mol. wt. of 1500. The III fraction with stearoyl chloride produced solids in the case of the 10 and 33% runs, which upon heating gave hard solids, while higher proportions showed little tendency to polymerize further upon heating. Oleoyl chloride and III yielded products ranging from solids to viscous liquids as the % of the former was increased; all of these changed to hard, flexible resins upon heating. With 33 and 67% linolenoyl chloride a viscous liquid and hard resin, resp., were obtained, both polymerizing further in air and formed hard resins when heated. The I resin, m. 94° (ball and ring) was acylated in same manner and the products are tabulated; the mol. wt. of product from equimol. proportions of stearyl chloride was 971.6. Solubilities in various solvents and stability toward H_2O, 18% HCl and 20% NaOH, are described. John F. Lontz

Copolymerization of maleic polyesters. John B. Rust. *Ind. Eng. Chem.* **32**, 64–7(1940).—Diethylene glycol (6.32 mols) and 6.12 mols of maleic anhydride, heated at 200° for 8 hrs., yield a viscous, clear ester (I) by linear condensations; when this ester was heated 50 hrs. at 50° with Bz_2O_2 (added in C_6H_6 soln.), a hard clear tough machineable resin was produced by addn. polymerization involving the system —C=C—C=C—O. Bz_2O_2 and acetyl benzoyl peroxide catalyze copolymerization of I with vinyl derivs. (such as vinyl acetate), the properties of the final product depending upon the catalyst, temp. and ratio of vinyl deriv. to I. After an induction period, copolymerization proceeds in definite stages wherein are successively produced (1) a slimy gelatinous mass, (2) a gel, (3) a hard rubbery mass, (4) a soft flexible resin and (5) a tough glassy solid. In mixts. of I and vinyl acetate, clear cured resins are obtained only with vinyl acetate concns. up to 32%, since insol. polymerized vinyl acetate is probably formed in more concd. mixts. Styrene has approx. the same limit of compatibility as vinyl acetate, while mixts. of equal parts of styrene and vinyl acetate yield clear cured masses in amts. up to 40% of the casting soln.; Me methacrylate is compatible in all proportions. George Ayers

Ash-forming constituents of [electrical-] insulating papers. D. A. McLean. *Ind. Eng. Chem.* **32**, 209–13(1940).—The ability of cellulosic materials (insulating paper) to neutralize dil. acids and bases and to soften H_2O (*C. A.* **33**, 9626[9]) is attributed to exchange reactions occurring at the acidic groups assocd. with the noncellulosic components pectic substances and lignin). The mechanism of these exchanges is described. It is shown that the acid neutralization value is directly proportional to the ash content of the paper and that it is equiv. to the alky. of the ash. The metallic constituents of the ash (Si, Fe, Cu, Mn, Ca, Mg) are present in the paper as metallo-org. compds. which enter into the exchange reactions. The ash content is not appreciably reduced by prolonged H_2O extn. but is by extn. with dil. HCl. Washing the acid-extd. paper with $CaCl_2$ restores the ash content. Pentosans are not removed by acid extn. Detns. were made of β- and γ-cellulose, lignin and uronic acid anhydride. These are shown to contribute to the cation exchanges. Fourteen com. insulating papers (kraft, linen and hemp) were used in this study. All expts. are described and the data are given in tables and graphs. 10 references. A. J. S.

Synthetic resin adhesives. A. Foulon. *Nitrocellulose* **10**, 221–3(1939); cf. *C. A.* **33**, 830[3].—A review. E. M. Symmes

The utilization of phenol-lignin resin for gluing plywood. G. D. Kreitser and O. M. Klimova. *Lesokhim. Prom.* **1938**, No. 3–4, 22–4; *Khim. Referat. Zhur.* **2**, No. 4, 130–1(1939).—Phenol-lignin resin to which was added 14% by wt. of urotropine was a suitable adhesive for plywood. Cleaving strength of 30 kg./sq. cm. was obtained. W. R. Henn

Modern adhesives. Synthetic glues in the veneer and plywood industry. S. Horwitz. *Wood* **5**, 4–7(1940); *C. A.* **34**, 1413[9].—A discussion of the use of blood albumin glues, water glass, cellulose ester adhesives and synthetic-resin adhesives. Leopold Scheflan

The development of modern surface-active materials. I. Wetting, foaming, detergent and emulsifying agents. Their properties and actions. J. W. Orelup. *Progressive Perfumery & Cosmetics* **1937**, 5–7.—A review. L. S.

Detergents from kerosene. Alkyl sulfates. A. R. Padgett with Ed. F. Degering. *Ind. Eng. Chem.* **32**, 204–8 (1940).—A 95–100° fraction of kerosene was chlorinated to 25–33% and aerated to remove HCl. The 120–135° fraction of monochlorides was isolated in 80–90% yield. One mole of this added to 1 mole of NaOH in H_2O and AmOH was hydrolyzed at 160–170° for 9 hrs. After distn. of H_2O with some AmOH the alcs. were extd. with Me_2O. The 125–140° fraction gave 30% yield. Treatment with $HOSO_2Cl$ followed by $NaHCO_3$ gave Na alkyl sulfates in 55% yield. This was compared with the Na 2′, 3′, 4′, 5′ and 6′ dodecyl sulfates prepd. from the pure alcs., Na lauryl sulfate and the product extd. from "Dreft" with alc. Both by measurement of stability of foam and the interfacial tension when 0.2% soln. are dropped in benzene the order of effectiveness decreases progressively from the primary through the order 2,3,4,5,6-dodecyl sulfates. Of the primary sulfates the foam test shows the "Dreft" ext. best, Na lauryl sulfate next and the kerosene deriv. close to the Na 2-dodecyl sulfate. By interfacial tension measurement there is little choice between the kerosene deriv. and Na lauryl sulfate, and the "Dreft" ext. is nearly as good. Foster Dee Snell

Casein, its production and uses. Knut A. Wickman. *Kgl. Lantbruksakad. Tid.* **78**, 367–85(1939)(summary in German).—A lecture including a description of the compn. and properties of casein, the prepn. of rennet and acid caseins, the importation and exportation of casein by Sweden, the prepn., properties and uses of galalith, casein glue and, especially, lanital, and the use of casein in the *paper, textile* and *paint industries* and in *medicine*. The possibility of the eventual production of lanital in Sweden is discussed. Ruth Berggren

Airplane dope. Relation of tautening and weathering qualities to composition. Frank W. Reinhart and Gordon M. Kline. *Ind. Eng. Chem.* **32**, 185–93(1940); cf. *C. A.* **32**, 5101[3].—Evidence is given to show that cellulose acetopropionate and cellulose acetobutyrate are probably the only satisfactory plastic bases for use in place of the hazardous cellulose nitrate in airplane dopes. In these the optimum hydroxyl content is about 0.2 equiv. Aryl phosphate plasticizers give the best initial tautness which is maintained during exposure. A close correlation is shown to exist between the properties of unsupported films and the behavior of doped fabrics. This may result in a considerable saving in time, labor and material in the preliminary evaluation of new compds. and formulas. Henry J. Wing

Pendulum and "cloudburst" methods of measuring and testing hardness. S. R. Williams. *Instruments* **12**, 257–61, 301–3(1939). E. H.

Electricity in chemical plants. Kennard Pinder. *Elec. Eng.* **59**, 77–83(1939).—Chemical plants are among the largest users of electricity. P. discusses precautions to be observed in selecting elec. equipment because of flammable or corrosive fumes. C. G. F.

Entomological branch. C. F. C. Beeson. *Rept. Forest Research India* **1937–38**, Pt. 1, 33–9(Pub. 1939); *Rev. Applied Entomol.* **27A**, 611–12.—Owing to the use of flour paste in their manuf., pith helmets are attacked by *Rhizopertha dominica* F. Of insecticides tested for use in the paste 10% Na_2SiF_6 was as effective as 3% soln. of As_2O_3 and $CuSO_4$ (3:1), but both were inferior to a 3.5–4% soln. of As_2O_3 and $CuSO_4$. $CuSO_4$ alone is least effective. Edwin J. Seiferle

Studies on repellents for biting flies. C. G. MacNay. *Can. Entomol.* **71**, 38–44(1939).—Expts. were undertaken to det. which of many materials, cited in the literature as repellents for blood-sucking Diptera, were most effective and which were most lasting in effect. The materials

tested were incorporated in olive oil for application. The mosquitoes present in the wooded areas of Ontario where the tests were made were chiefly *Aedes hirsuteron*, *A. stimulans*, *A. vexans* and *A. trichurus*. Results showed a mineral oil ext. of pyrethrum, 1 fluid oz. of which contained the ext. of 0.2 lb. of pyrethrum flowers, to be the most promising of the materials tested. Various forms of essences of thyme and geranium were promising. Cinnamaldehyde and cresol, although comparatively effective, were too irritating to the skin to be useful. Ph salicylate, bay laurel, pine oil, clove and citronella possessed some value. Fractions of oil of tar obtained by distn. were all apparently fairly effective and, being colorless, did not possess the objectionable qualities of the original tar-oil. Numerous other compds. and mixts. were of less value and some were also irritants. Edwin J. Seiferle

Patent litigation in 1939. Nelson Littell. *News Ed.* (*Am. Chem. Soc.*) **18**, 97–101(1940); cf. *C. A.* **33**, 1411[6]. E. J. C.

Ether-esters of alkoxybenzoic acids. Ernest F. Grether and Russell B. DuVall (to Dow Chemical Co.). U. S. 2,176,070, Oct. 17. Ether-esters generally suitable for use as *plasticizers for nitrocellulose, cellulose acetate* and *ethylcellulose* or the like are obtained by treating an ether-ester of a hydroxybenzoic acid, such as β-ethoxyethyl salicylate with an alkylating agent such as Et_2SO_4, EtCl, diisopropyl sulfate or the like (various details for regulating the reaction being described). The β-ethoxyethyl 4-ethoxybenzoate is a colorless liquid. The β-ethoxyethyl 2-methoxybenzoate b_4 135–40°. The β-ethoxyethyl 4-methoxybenzoate b_2 120–30°. Other esters are mentioned; e. g., β-ethoxyethyl 3-hydroxybenzoate may be treated with diamyl sulfate to produce β-ethoxyethyl 3-amoxy-

benzoate; β-naphthoxyethyl 2-hydroxybenzoate with BuCl to produce β-naphthoxyethyl 2-butoxybenzoate; phenoxyethoxyethyl 4-hydroxybenzoate with Me_2SO_4 to produce β-(phenoxyethoxy)ethyl 4-methoxybenzoate; 3-propoxybenzoic acid with monoisopropyl ether of trimethylene glycol to produce γ-isopropoxypropyl 3-propoxybenzoate; 4-methoxybenzoic acid with mono-*o*-xenyl ether of ethylene glycol to produce β-*o*-xenoxyethyl 4-methoxybenzoate; 3-ethoxybenzoic acid with 2-chlorophenoxy ether of ethylene glycol to produce β-2-chlorophenoxyethyl 3-ethoxybenzoate; 2-methoxybenzoic acid with ethyl ester of triethylene glycol to produce the ω-monoethyl ether of triethylene glycol monoester of 2-methoxybenzoic acid; 2-ethoxybenzoic acid with 2-methylphenyl ether of diethylene glycol to produce β-(β-(2-methylphenoxy)ethoxy)ethyl of 2-ethoxybenzoate; etc.

Ethers of hydrogenated phenols. Harold R. Slagh and Francis N. Alquist (to Dow Chemical Co.). U. S. 2,181,100, Nov. 21. Compds. which may be used as *modifiers for synthetic plastics*, as *perfume bases*, or as *insecticides*, and which have the general formula $XOCH_2$-$\overset{\displaystyle R}{\underset{\displaystyle CH_2.O}{C}}$ in which R represents H or CH_3 and XO represents a hydrogenated phenol residue (inclusive of residues derived from hydroxy compds. produced by the catalytic hydrogenation of phenol and nuclear-substituted derivs. such as cyclohexanol, halocyclohexanols, alkylcyclohexanols, tetrahydronaphthols, cyclohexylphenols, phenylcyclohexanols, cyclohexylcyclohexanols, etc.) are prepd. by treating a Na salt of a hydrogenated phenol compd. with 1-chloropropylene 2,3-oxide or 1-chloro-2-methylpropylene 2,3-oxide in the presence of an inert solvent such as toluene or benzene, as by heating to 60° or a higher temp. Details are given of the production of 1-(2-phenylcyclohexyloxy)propylene 2,3-oxide, a mobile water-white liquid, 1-(cyclohexyloxy)propylene 2,3-oxide, a sweet smelling oil, and 1-(2-cyclohexylphenoxy)propylene 2,3-oxide, also a sweet smelling oil, and general mention is made of the production of corresponding ethers of 2-chlorocyclohexanol, 2-methylcyclohexanol, 4-*tert*-butylcyclohexanol, tetrahydro-1-naphthol, 4-cyclohexylphenol, 2-chloro-4-cyclohexylphenol, 2-cyclohexyl-4-*tert*-butylphenol, 3-phenylcyclohexanol, 4-cyclohexylcyclohexanol, etc. 3

Molding machine for plastic material. John Lauterbach (to Owens-Illinois Glass Co.). Can. 386,346, Jan. 16, 1940. Structural details. 4

Casein compositions suitable for molding. Jean Delorme (to George Morrell Corp.). U. S. 2,180,626, Nov. 21. A thermoplastic solid material is prepd. by subjecting an acid casein to the action of a benzyl compd. such as benzyl chloride in the presence of EtOH and an alkali carbonate, first at normal room temp. not exceeding 70° for a period less than 14 hrs. and afterward continuously mixing the ingredients and subjecting them to a temp. of about 80° for 4–8 hrs. and until a smooth homogeneous paste is produced. 5

Molded articles such as laminated material comprising phenolic resin. Harry M. Dent and Arthur J. Norton (to General Plastics, Inc.). U. S. 2,180,934, Nov. 21. A core contg. about 15–20% of a hardened phenolic resin and a filler is provided with surface-strengthened exterior faces contg. about 60–65% of such resin. 6

Molded bodies of synthetic resin containing photographic designs. Walter D. Ford. U. S. 2,180,002, Nov. 14. A cast color-contg. substantially transparent body of synthetic resin compn. is formed having an undulous photographic design molded in its inner surface, the obverse surface of the body being smooth, regular and unbroken, the transparency and varying thickness of the body in the area of the design producing light and shadow variations to render the detail of the design clearly viewable through the body from the obverse surface. 7

Apparatus for treating thermoplastic material, as in preparing synthetic resins, etc., for molding. Ralph E. Thompson. U. S. 2,179,968, Nov. 14. Various structural and operative details. 8

Artificial resins. Vereinigte chemische Fabriken Kreidl, Heller & Co. Nfg. Fr. 840,900, May 5, 1939. Substances contg. one or more ethylenic bonds, such as styrene, acrylic and methacrylic acids, vinyl and acrylic esters, are polymerized wholly or in part in the gaseous, or a semi-gaseous state, in the presence of the usual catalysts without any solvent. The speed of the reaction and the degree of polymerization are regulated by the pressure, temp. and concn.; these are regulated by the addn. of an inert gas. 9

Artificial resins. I. G. Farbenind. A.-G. Fr. 841,028, May 9, 1939. The resins are obtained by condensing benzyl halides, substituted or not, or their homologs, in absence of condensing agents at a temp. which is gradually raised to 180°. The condensation is terminated when the evolution of hydrogen halide (a by-product in the reaction) ceases. The resins manifest greater elasticity and adhesive power when the condensation is made in presence of aromatic hydrocarbons. After the condensation, the resins are subjected to a complementary treatment, which consists in adding to them in their molten state, small quantities of basic substances, such as NH_3, amines, monophosphate of NH_4, urea or formamide. The resins are sol. in benzene, toluene, xylene, styrene, CCl_4, Me-benzene and decahydronaphthalene, insol. in the lower alcs., acetone, cyclohexanol, cyclohexanone and acetate of cyclohexanol. They are completely insol. in mineral acids and are therefore particularly suitable as a coating material for vessels and other instruments in contact with acids. 10

Phenol-aldehyde resins. Edmond F. Fiedler (to General Elec. Co.). U. S. 2,180,981, Nov. 21. A method of making a permanently fusible phenol-aldehyde resin involves treating a phenol and an aldehyde in the presence of an acid catalyst, partly dehydrating the reaction product under reduced pressure until it has a flow point of about 60–90°, neutralizing the partly dehydrated product, and dehydrating the neutralized product under pressure until substantially all the remaining water has been removed. 11

Alkyd resin suitable for coatings, etc. Horace A. Hampton, Arthur Hill and Edwin B. Robinson (to Imperial Chemical Industries Ltd.). U. S. 2,181,054, Nov. 21. A synthetic resinous material is obtained by a process which involves causing to react at 170–240° pht halic anhydride, a drying oil acid, semidrying oil acid or a glyceride of such acids, 20–40% of colophony and 2.5–7% of maleic acid, the amts. of colophony and maleic acid being based on the wt. of the fatty ingredient, and a polyhydric alc. in amt. not substantially exceeding a 10% excess over that required to esterify the total acidic reagents employed. 12

Resinification of terpene hydrocarbons. Joseph H. James (to Clarence P. Byrnes, as trustee). U. S. 2,180,418, Nov. 21. A terpene hydrocarbon mixt. such as a Georgia pine oil is heated and treated with a gas contg. free O under conditions producing a liquid formed mainly of mixed O derivs. of terpene hydrocarbons, and the product is resinified. Several examples with details are given. 13

Finely divided resin. Carlton R. Ferris and Estol T. Carte (to Carbide and Carbon Chemicals Ltd.). Can. 385,888, Dec. 26, 1939. A soln. of vinyl resin in a volatile solvent is atomized in a stream of a highly heated inert fluid contg. small amts. of the vapors of the solvent and unchanged polymerizable vinyl compds., the soln. having a total-solid content of about 12%. The resin in finely divided form is cooled below its softening temp. and sepd. from the fluid stream. The fluid stream is cooled to condense and recover the solvent and unchanged vinyl compds. An app. is described. 14

Resinous condensation products. I. G. Farbenind. A.-G. Fr. 840,826, May 3, 1939. Polycarboxylic acids, phthalic anhydride, or phthalic acid esters are condensed with compds. contg. reactive OH groups, which tend to polymerize and condense themselves or the products they form, in presence, or in absence of solvents and thinners. Examples are given. 15

Insulating electrical conductors such as wires. Edward C. Strube (to American Anode Inc.). U. S. 2,179,965, Nov. 14. App. and operative details are described, for providing an elec. conductor with an *in situ* deposit of solids from latex, the deposit including the water-insol. reaction product of a metallic salt such as one of Zn

and at least some of the normally water-sol. ingredients of the deposit naturally occurring in the latex.

Sound and vibration insulating panels. Edwin O. Groskopf (to Patent and Licensing Corp.). U. S. 2,180,305, Nov. 14. A method of uniting a layer of relatively impermeable fibrous sound-deadening or vibration-damping material such as felt to the surface of an impervious metal panel or the like involves ifterposing between the materials a film of an aq. emulsion of a waterproof substance such as asphalt, etc., contg. an inverting agent such as kerosene to cause the emulsion to coalesce when 20–90% of its original water content still remains in the film and subjecting the assembled materials thereafter to temps. above 100° so that the film will hold the assocd. materials against displacement from each other during conversion into steam of the remaining water content of the film.

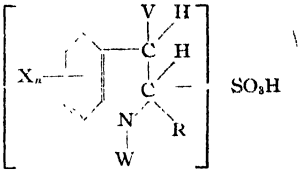
Wall heat insulation formed of materials such as "rock wool." Edwin H. Wenzel. U. S. 2,179,678, Nov. 14. Various structural details.

Polyvinyl halide compositions. Claude H. Alexander (to B. F. Goodrich Co.). U. S. 2,179,073, Nov. 14. Compns. suitable for *elec. insulation* comprise a polyvinyl halide and a silicate of Ca, Ba, Sr, Pb or Ag. Cf. *C. A.* 34, 831[8].

Etching spark-plug insulators. Richard Stribeck (to Robert Bosch G. m. b. H.). U. S. 2,180,779, Nov. 21. For improving the stability to temp. change of spark-plug insulators consisting of a burnt ceramic mass of insol. and sol. components such as corundum and ceramic material, the insulators are superficially etched with an etching medium such as HF or KOH which attacks the sol. components but does not substantially attack the insol. components.

Adhesive suitable for wall-paper hanging. Rudolf Köhler (to Henkel & Cie., G. m. b. H.). U. S. 2,180,152, Nov. 14. A viscous aq. colloidal soln. is used contg. 3–8% of a water-sol. salt of an ether of cellulose with a lower mol. carboxylic acid such as the Na salt of a cellulose ether glycolic acid.

Wood-veneer glue. Russell G. Peterson (to George H. Osgood). U. S. 2,180,547, Nov. 21. A glue having a consistency adapting it to be applied by rolls contains an artificial resin partial condensation product such as a urea-formaldehyde condensation product and a cellulosic flour such as a wood flour, together with $NaNO_3$ or KNO_3, which serve to give the product good quality of penetration and strength.



Glue bases. Geo. H. Osgood. U. S. 2,180,542, Nov. 21. A glue base suitable for use with an alk. medium comprises a protein material such as milk casein, blood albumin or egg albumin, used together with seed hulls such as pea hulls, which are impregnated with the protein in pptd. condition. Glues formed from such material are suitable for use with wood plies, etc. U. S. 2,180,543 relates to a wood-veneer casein glue having the desired body and working life, adapted to form a bond of the desired strength and water resistance, and comprising an admixt. of an aq. alk. medium, isolated milk casein and Na formaldehyde bisulfite, as sep. ingredients, the amt. of the water being at least 4 times the amt. of the casein whereby the amt. of Na formaldehyde bisulfite may be at least about 2.75–3.0% of the amt. of casein.

Wetting, cleansing and dispersing agents for use in textile treatments, etc. Fritz Guenther and Karl Saftien (to I. G. Farbenind. A.-G.). U. S. 2,169,976, Aug. 15. By treating an amine contg. at least one aliphatic radical with at least 8 C atoms and at most one H atom directly attached to N, such as stearoyldiethylethylenediamine, with an oxidizing agent, such as Caro's acid, there are obtained textile assistants of the general formula $R_1R_2R_3N(OR_4)OH$, where R_1, R_2, R_3 and R_4 stand for aliphatic or aromatic radicals, at least one of which radical contains an aliphatic chain of at least 8 C atoms. Numerous examples with details are given.

Aromatic aliphatic ether chlorides. Herman A. Bruson (to Röhm & Haas Co.). U. S. 2,176,834, Oct. 17. A process of prepg. compds. of the general formula $R_1R'(OA)_nCl$ in which R is a cycloaliphatic radical, R′ is an aryl radical, A is an alkylene radical having at least 2 C atoms or a polyalkylene ether radical in which the alkylene groups contain at least 2 C atoms and n is an integer less than 8, involves heating a cycloaliphatic alc. or cycloaliphatic compd. contg. an olefin linkage with a polyalkylene ether chloride $R'(OA)_nCl$ in the presence of a surface-active siliceous clay catalyst to temps. of about 180–210°. Details are given of the production of β-camphylphenoxy-β′-chlorodiethyl ether, b_{1-2} 205–20°, and various related compds. which may be sulfonated to produce *wetting, emulsifying, cleansing* and *dispersing agents*.

Sulfonic acids of aromatic compounds. Charles A. Thomas (to Sharples Solvents Corp.). U. S. 2,180,314, Nov. 14. Sulfonic acids of polyphenyl polynaphthyl derivs. of paraffin hydrocarbons contg. 8–20 C atoms and their alkali metal salts are useful as *washing, wetting* and *emulsifying agents*, details being given of the production of the Na salt of phenyldecylbenzenesulfonic acid, the Na salt of naphthyldodecylnaphthalenesulfonic acid, etc.

Sulphonated indole derivatives. Kurt Engel (to J. R. Geigy A.-G.). U. S. 2,180,801, Nov. 21. *Wetting, dispersing, emulsifying, penetrating* and *washing agents* (suitable for emulsifying Ca soaps) are produced, which are sol. salts of indolesulfonic acids of the general formula

where R is a high-mol. aliphatic radical with more than five C atoms, W being one of the group consisting of H, alkyl, benzyl and phenyl, V being a member selected from the group consisting of H, alkyl, benzyl and phenyl groups, and X represents H or methyl, n being 1 or 2, the salts being when neutralized and evapd. white to slightly colored powders, sol. in water to clear solns. As initial materials, use may be made of the indole prepd. from palm-nut fatty acid *o*-toluidide or its dihydro reduction product, α-heptadecenylindole, an indole prepd. from hydrogenized cod-liver oil fatty acid benzyl-*o*-toluidide, etc.

Quaternary ammonium derivatives of amides. Albert K. Epstein and Morris Katzman. U. S. 2,176,896, Oct. 24. *Wetting, detergent* and *emulsifying agents*, etc., suitable for use in various processes are produced, which have the general formula $RCON(Y)(CX_2CX_2'NX'')_nOCZ(N(A)=)_m$, where RCO is an acyl radical contg. at least 4 C atoms, Y, X, X′ and X″ are the same or dissimilar members selected from the group consisting of H, alkyl, cycloalkyl, and alkylol, Z is a hydrocarbon residue, A is an anion, m and n are whole numbers, and at least one of the 3 indicated valence bonds attached to N is satisfied by a radical of the class consisting of alkyls, cycloalkyls, alkylols, aralkyls, aryls, aralkylols, and the radical of a heterocyclic ring of which the N is a member. These products, in general, are prepd. by initially treating a polyamine, e. g., ethylenediamine with a higher-mol.-wt. carboxylic acid or deriv. thereof such as halide, under conditions such as to ensure a substantial yield of amide. The resulting amide is then treated with a preferably lower-mol.-wt. halocarboxylic acid or halide or other deriv. thereof to produce another amide linkage and with an org. nitrogenous base such as pyridine to produce a quinquevalent nitrogen. The order of the steps may be reversed, if desired; that is the reaction with the higher-mol.-wt. acid or deriv. thereof may be carried out last, or the two amidification steps may be carried out in optional order and the reaction with the pyridine or the like may be carried out thereafter. Numerous examples with details are given.

Basic condensation products. Valentin Kartaschoff (to Chemische Fabrik vorm. Sandoz). U. S. 2,180,809, Nov. 21. See Fr. 828,619 (*C. A.* 33, 2817).

Fabric-reinforced artificial leather. Milton O. Schur and Benjamin G. Hoos (to Brown Co.). U. S. 2,180,723, Nov. 21. App. is described, and a method of producing a sheet of fabric-reinforced, binder-impregnated felt suitable for use as a leather substitute which involves progressively and simultaneously passing a felt and a fabric such as a reinforcing cloth under separately applied tensions through a bath of settable liquid binder such as a rubber latex compn. in which the lower roll of a pair of squeeze rolls rotates partially submerged, causing the wet impregnated felt and the wet impregnated fabric to pass in superposed relationship about the submerged periphery of the lower roll and thence into the nip of the rolls with the felt lying directly on the submerged periphery, maintaining the tension on the fabric greater than on the felt as they are passing into the bath and about the lower roll, and setting the binder content of the composite sheet being progressively delivered by the squeeze rolls. Cf. *C. A.* **34**, 1987.

Leather substitute. Geza Ganz. Fr. 841,007, May 9, 1939. A thin layer of fibrous matter, such as felt or linen cloth, is impregnated with a liquid mixt. contg. casein, rubber or rubber latex, a small quantity of finely divided S, 4–5% of oil and some sugar, dried, treated with acetic acid and alum or with a soln. of tannin, dried again and vulcanized. Instead of casein, skimmed sour milk is used advantageously.

Rubber-like polymerization products. Martin Müller-Cunradi and Walter Daniel (to I. G. Farbenind. A.-G.). U. S. 2,180,082, Nov. 14. Butadiene or a substitution product such as isoprene, etc., is polymerized in the presence of solid highly polymerized isobutylene. U. S. 2,180,083 relates to the similar polymerization of vinyl carbazole.

Polymerizing unsaturated hydrocarbons. Raymond C. Lassiat (to Houdry Process Corp.). U. S. 2,180,361, Nov. 21. An arrangement of app. is described, and a process which involves admitting a hydrocarbon material contg. unsaturates such as C_4H_8 and C_3H_6 for the polymerization reaction and high-boiling material to a fractionating zone, withdrawing from the latter a distillate fraction composed, to substantial extent, of the unsaturates, subjecting the latter under polymerizing conditions to a polymerizing operation, sepg. from the resulting products a cut comprising polymers and an excess of hydrocarbons b. within the boiling range of the distillate fraction mentioned, and feeding the cut to the fractionating zone at a level sep. from but adjacent and below that for the admission of initial hydrocarbon material mentioned, thereby simultaneously to blend the polymers with the higher-boiling material and minimize loss to the resulting fluid of desired unsaturates in the starting material. Cf. *C. A.* **33**, 7815[2].

Polymerization of chlorohydrocarbons. Röhm and Haas A. G. Fr. 840,867, May 5, 1939. $(:CHCl)_3$ is polymerized by light, heat, pressure, oxygen, H_2O_2, tetralin peroxide, benzoyl peroxide, etc. The products are 90–9% liquid dimers with a small residue of solid polymers. The liquids are incombustible, have a certain narcotic power, and may be used as solvents, detergents, softeners, artificial waxes and as intermediaries for the prepn. of synthetic products.

Detergent compositions. Coleman R. Caryl and Alphons O. Jaeger (to American Cyanamid & Chemical Corp.). U. S. 2,181,087, Nov. 21. A stable neutral powder, noncaking and readily sol. in water, comprises a spray-dried mixt. of the sulfosuccinic ester of an aliphatic alc. having 5 to 8 C atoms and a water-sol., nonhygroscopic carrier such as Na_2SO_4, which is stable at spray-drying temps. and the satd. soln. of which has a pH of 6.5–8.5.

Protective coating for construction materials. Leon Billé. Fr. 841,112, May 10, 1939. Asbestos fibers and natural or artificial cement are mixed and kneaded, while cold, with a paint or a soln. of an adhesive, to form a coating for construction materials against corrosion. Lime or an aggregate of sand, limestone dust, emery or carborundum is added to increase the hardness of the coating.

Stabilizing zein solutions. Corn Products Refining Company. Fr. 840,862, May 5, 1939. All of the insol. protein such as denatured zein, which acts as a catalyst and causes the zein to become insol., is eliminated from the zein soln. by filtration. To obtain good results all or at least a part of the following conditions should be observed before the filtration. (1) The soln. is cooled to a temp. slightly below 20°, (2) the pH regulated to 7.4, (3) the soln. is aged, before clarification, (4) treated with an absorbing agent such as animal charcoal and then (5) mixed with a corn-oil solvent.

Activators for oxygen baths, preventing separation of hydroxy compounds of heavy metals. Richard Neu (to "Unichem" Chemikalien Handels A.-G.). U. S. 2,176,508, Oct. 17. A bleaching bath or other O bath comprising an aq. soln. of an active O-yielding compd. selected from peroxides, perborates, persulfates, and percarbonates contains, as an addnl. ingredient, an activator which comprises a product resulting from the reaction of an amine from the group which consists of alkylamines, hydroxyalkylamines, amino alcs., ethers of amino alcs., amino alkyl polyalcs., amino alkyl thiols, and cyclic amines; with a salt of Cu, Mn, Ni, Co, Fe or Ag, the salt being a H_2SO_4 deriv. of an org. compd. of high mol. wt. having the general formula: $R—X_L—R'(Y_L—SO_3H)_n$, where R represents a high-mol.-wt. hydrocarbon radical contg. from 6 to 30 C atoms; X represents a radical selected from the group which consists of S, O, COO, OCO, NR″, SO_2, NR″SO_2, and CONR″; R′ represents a radical selected from the group which consists of the alkylene radicals, hydroxyl substituted alkylene radicals, halogen substituted alkylene radicals, and arylene radicals; R″ represents H or a hydrocarbon radical; Y represents S or O; *n* represents 1 or 2; and L represents 0 or 1. Among suitable activators are: the Cu salt of the dodecyl H_2SO_4 ester with triethylamine; the Mn salt of the glycerol monododecyl H_2SO_4 ester with triethylanolamine; and the Co salt of the oleylmethylaminoethanesulfonic acid with γ-amino-α,β-propylene glycol.

Antifreeze composition. Ben W. Jarboe. Can. 386,547, Jan. 30, 1940. A cooling medium, m. about −50°F., b. about 225°F., d. about 1.26, consists approx. of $CaCl_2$ 4.25 lb., $Na_2Cr_2O_7$ 0.05 lb., oil 0.02 gal., and water to make 1 gal. of mixt.

Foundry-core materials. Harold K. Salzberg (to Borden Co.). U. S. 2,181,004, Nov. 21. Finely divided relatively inert solid material such as sand is used with a binder consisting principally of a mixt. of milk solids with an acid or salt such as Na oxalate capable of and in sufficient amt. for reacting in water with the Ca of the milk solids to form a Ca salt less sol. in water than $Ca_3(PO_4)_2$.

Magnetic cores. C. Lorenz A.-G. Fr. 840,991, May 8, 1939. See Brit. 502,394 (*C. A.* **33**, 7445[2]).

Finely divided magnetic substances. Rudolf Brill and Karl Schoenemann (to I. G. Farbenind. A.-G.). U. S. 2,179,810, Nov. 14. Mixed crystals of at least one oxide of a magnetic metal such as Fe_2O_3 and smaller amts. of at least one oxidic addnl. substance such as CaO or Al_2O_3 which is capable of forming mixed crystals with the first mentioned oxide and is more difficultly reducible are subjected to a reducing treatment (such as heating with H) effective for the reduction of the first mentioned oxide only and the reduction product is comminuted to obtain finely divided magnetic material suitable for *sound-record carriers*, etc.

Synthetic skating surface. Andrew S. MacBride. U. S. 2,179,664, Nov. 14. Skating surfaces are formed of a mixt. of naphthalene 7, gum dammar 2 and carnauba wax 10 parts with a surface lubricant such as an oil.

Chemical heating pad for permanent hair waving. Frederick L. Reynolds (to United States Appliance Corp.). U. S. reissue 21,276, Nov. 21. A reissue of original patent No. 2,153,678 (*C. A.* **33**, 5556[3]).

Polystyrene films. Edgar C. Britton, Harry B. Marshall and Clyde W. Davis (to Dow Chemical Co.). U. S. 2,179,975, Nov. 14. Polystyrene is used with a solvent consisting essentially of an aromatic hydrocarbon such as xylene, toluene or benzene or a chlorinated aromatic hydrocarbon such as mono- or di-chlorobenzene together with

about 1–5% of dioxane, which serves to facilitate removal of films from casting surfaces.

Translucent screen suitable for use in viewing projected images. Edwin H. Land (to Polaroid Corp.). U. S. 2,180,113, Nov. 14. Various details of manuf. are described of a sheet of transparent plastic material such as a cellulose acetate compn. contg. distributed particles such as globules of glycerol.

Composition suitable for sealing wounds of plants. Martin Müller-Cunradi, Michael Otto, Walter Daniel and Robert Werner (to I. G. Farbenind. A.-G.). U. S. 2,180,081, Nov. 14. Use is made of a high.-mol. polymer of an isoölefin such as that of isobutylene (suitably with brown-coal-tar pitch, or tetrahydronaphthalene, paraffin oil and wool grease).

Waterproofing composition suitable for use on various materials. Arthur F. Taggart and Warley L. Parrott. U. S. 2,180,971, Nov. 21. A mobile, liquid, penetrative waterproofing compn. that forms upon evapn. of its volatile constituents a fine-grained to glass-like water-repellent film, comprises a normally solid water-repellent crystallizable org. material selected from the group consisting of fats and waxes of org. origin, an evapg. hydrocarbon solvent, and a natural asphalt, mixed in such proportions that upon concn. of the compn. the natural asphalt and hydrocarbon solvent will thicken before the crystallizable material begins to precipitate, whereby the natural asphalt arrests the normal crystal growth of the crystallizable material as it ppts. from the solvent, and causes the crystallizable material to ppt. in the form of extremely fine size crystals.

Packing material. I. G. Farbenind. A.-G. Fr. 840,-905, May 5, 1939. Flax, hemp or other fibrous matter is covered with a thin protective film by immersing it in an aq. suspension or in an org. soln. of polyvinyl chloride and then passing through the heated rollers of a calender.

Ethers suitable for use in fly spray compositions. Francis N. Alquist and Harold R. Slagh (to Dow Chemical Co.). U. S. 2,181,085, Nov. 21. Various details are given of the production of ethers such as 1-(2-phenylphenoxy)-propylene 2,3-oxide, b_{12} about 190–200°; 1-(3-phenyl-, (2′-bromo-4-phenylphe-, about 230–41°; by treating 1-chloropropylene 2,3-oxide or 1-chloro-2-methylpropylene 2,3-oxide with an aq. soln. of an alkali metal salt of a suitable phenylphenol compd. The reaction mixt. is stirred and warmed at a temp. between 60° and the refluxing temp. thereof until the reaction is substantially complete. The mixt. is then cooled, the crude ether product sepd. therefrom as by decantation, extn., or filtration, and thereafter fractionally distd. to obtain the desired ethers in substantially pure form. An alternative procedure consists of treating metallic Na with a phenylphenol dissolved in a suitable water-free org. solvent such as benzene, and subsequently heating the reaction mixt. with a chloropropylene oxide compd. to form the desired compd. In a like manner, the phenylphenols and their nuclear-substituted derivs. may be treated with 1-chloro-2-methylpropylene 2,3-oxide, i. e., chloroisobutylene oxide, to produce homologous 1-(aryloxy)-2-methylpropylene 2,3-oxide, such as 1-(2-phenylphenoxy)-2-methylpropylene 2,3-oxide, and the like. These compds. are similar in characteristic to those disclosed above. By substituting other phenylphenol compds. there may be obtained the corresponding ethers of 2,6-dichloro-4-phenylphenol, 4-bromo-6-phenylphenol, 3-chloro-6-phenylphenol, 2-*tert*-butyl-4-phenylphenol, 2-octyl-6-phenylphenol, 2-benzyl-6-phenylphenol, 2-(δ-phenylbutyl)-4-phenylphenol, 4-cyclohexyl-6-phenylphenol, 2-methoxy-4-phenylphenol, 4-cyclopentyl-6-phenylphenol, 2-ethenyl-4-phenylphenol, 2,4-dinitro-6-phenylphenol, 2-chloro-4-phenyl-6-methylphenol, 2,4-dimethyl-6-phenylphenol, 2,4′-dichloro-4-phenylphenol, 2′,4′,6-tribromo-4-phenylphenol, 4′-isopropyl-6-methyl-4-phenylphenol, 2′-ethoxy-4-iodo-6-phenylphenol, etc.

Marking laundry. John L. De Fraine and James Y. Smith (Smith to De Fraine). U. S. 2,180,508, Nov. 21. A clear lacquer such as a vinyl resinoid compn. is used with a luminescent pigment such as ZnS, fluorene and retene to form markings which are substantially invisible under ordinary light but visible under ultraviolet rays.

14—WATER, SEWAGE AND SANITATION

EDWARD BARTOW

Deep waters in the subsoil of Western Libya. E. Niccoli. *Chim. ind. agr. biol.* **15**, 614-25(1939).—Analyses of 12 well waters of the Provinces of Tripolis and Misurata; from 3 wells a development of gas was observed (CH_4 82–97%). G. A. Bravo

Isotopic composition of water from some rivers and lakes of the U. S. S. R. R. V. Teis. *Compt. rend. acad. sci. U. R. S. S.* **24**, 779–82(1939)(in English).—A comparison of the densities of water samples taken in different points of the U. S. S. R., purified by the method of flotation temps. and the method of flotation pressures, furnished density differences ranging from 0 to 2.7 γ for the rivers and from +2.2 to 0 γ for the lakes. As a rule lake water is denser by 2 γ than river water. The water from the rivers of the Transbaikal region is lighter than that of the other rivers measured. The water of rivers and lakes fed with melting ice and snow has a lower density and cannot be used as a standard for density measurements. 7 references. A. H. Krappe

Chemical study on the removal of free acids in the river Tama. Hikoziro Miura. *J. Chem. Soc. Japan* **60**, 958–70 (1939).—Most of the free acid in the water can be removed by the addn. of a certain amt. of andesite or clay. T. K.

Corrosive rains in the Vesuvius region. Ottaviano Bottini. *Ann. chim. applicata* **29**, 425–33(1939).—Samples of rain waters collected in the Vesuvius regions contain up to 173 p. p. m. solids, and vary in pH from 2.78 to 6.99. Cl, SO_3, SO_4 and NO_3 ions have all been detected. A. W. Contieri

Determination of traces of titanium in natural waters. V. T. Chulko. *Zavodskaya Lab.* **8**, 950–2(1939).—Salts of quadrivalent Ti present in natural waters in amts. up to 0.001 mg./l. can be detd. colorimetrically with thymol and H_2SO_4 provided the Ti is ppted. along with the $Al(OH)_3$ coagulant at a pH greater than 6. Treat a 1-l. sample of water with enough soda so as to have a pH greater than 6 after it has been coagulated with alum soln. contg. 80–100 mg. Al_2O_3. Allow the mixt. to stay for several hrs., filter, and dissolve the ppts. in H_2SO_4. Boil the soln. with H_2O_2 until colorless, then filter, wash with 10% H_2SO_4 and H_2O_2, and evap. the filtrate to fumes of H_2SO_4. Dil. with concd. H_2SO_4 to 6–10 ml., add 3–5 drops of the reagent prepd. by dissolving 1 g. of thymol in a small amt. of 80% HOAc, and dil. to 100 cc. with concd. H_2SO_4. Compare the coloration with a standard soln. at the end of 30 min. B. Z. Kamich

The preparation of permutite by the wet method. M. V. Boltina and A. A. Mukhina. *Vodosnabzhenie Sanit. Tekh.* **1938**, No. 12, 15–17; *Khim. Referat. Zhur.* **2**, No. 4, 110(1939).—Permutite was obtained by the method of Dem'yanenko and Boltina (*C. A.* **26**, 5683). A method for the prepn. of the aluminate from a soln. of $Al_2(SO_4)_3 \cdot 18H_2O$ and NaOH and its purification from $Fe(OH)_3$ is given. By the reaction of a soln. contg. 150–200 g./l. of Na_2AlO_3 with 30°Bé. water glass, a gel is obtained after 2–3 min. It is dried in air for 24 hrs. at 80°, and sieved to a particle size of 0.1–2.0 mm. A highly effective permutite is obtained. About 1330 g. of alum, 600–700 g. of NaOH, 2–5 l. of water glass and 0.5–1 g. of Al powder are used for each kg. of permutite. W. R. Henn

Quality of lime desired for water treatment. Charles P. Hoover. *Am. Soc. Testing Materials, Symposium on*

Lime **1939**, 43–9(1940).—Lime for water treatment may be in lumps, pebbles or ground to suit the user's requirements. It should be fast slaking; 100 g. crushed to 1/4–1/8 in. added to 400 ml. distd. H_2O at 25° with const. stirring should show a temp. rise of at least 40° in exactly 3 min.; if it does not, the price should be penalized 1¢ per ton for each 2° the temp. rise falls short of 40°. The percentage of CaO which is most desirable depends upon local conditions; specifying 88% CaO, a bonus or penalty of 1 1/2% of the price for each 1% excess or deficiency in CaO detd. in each carload or day's delivery by truck is fair to both producer and consumer. The Scaife test for H_2O-sol. CaO is difficult to carry out properly; Ellms' test and the sugar test, easier and fully as satisfactory, are described. Elaborate detns. of inert materials are superfluous; only a knowledge of available CaO and slaking properties is necessary. Data on F in lime are included; analyses showed 50–340 p. p. m. With 100 p. p. m., a 20 gr./gal. dose could add only 0.034 p. p. m. F to the water. C. J. Schollenberger

Prevention of after-precipitation in lime-treated industrial and municipal waters by threshold treatment. Owen Rice, Everett P. Partridge and R. E. Hall. *Am. Soc. Testing Materials, Symposium on Lime* **1939**, 50–5(1940); cf. *C. A.* **33**, 1410[7], 1425[4].—Supersatn. of Ca salts in water supplies can be stabilized by addn. of Na hexametaphosphate, $(NaPO_3)_6$ (I). The process is termed threshold treatment because the required addn. is far below the stoichiometric relation; 1–2 p. p. m. is the optimum to prevent after-pptn. of $CaCO_3$ in CaO-treated water, deposition of scale in pipes and tanks, and to remove old scale by gradual soln. It is effective in domestic water heaters operating at 80° or even higher. Added prior to CaO-Na_2CO_3 softening, I largely inhibits cold softening, which is sometimes a useful property, but has little effect upon the hot process; it is believed that I prevents the formation of crystal nuclei of $CaCO_3$, so the soln. remains supersatd. indefinitely at the usual temps. I is absolutely nonpoisonous in the quantity used and the process has already been approved for use with public water supplies at a no. of places. It is believed that a very thin film of I is adsorbed upon surfaces, not preventing the gradual soln., disintegration and complete removal of old scale, but having a protective action upon metal surfaces and so preventing corrosion. C. J. Schollenberger

Scale prevention in gas and oil engines. F. J. Matthews. *Gas & Oil Power* **34**, 319–20(1939).—Carbonate deposits in engine jackets can be prevented by adding Na metaphosphate to the cooling water (0.5–2 lb. per 100,000 gal.). Even old deposits can be slowly removed by circulating water contg. 5 lb. of Na metaphosphate per 100,000 gal. George Ayers

The National Plumbing Laboratory. Francis M. Dawson and A. A. Kalinski. *Am. J. Pub. Health* **30**, 66 8 (1940). J. A. Kennedy

Industrial hygiene for the smaller plant. Glenn S. Everts. *Am. J. Pub. Health* **30**, 17–21(1940). J. A. Kennedy

Coliform bacilli and water supplies. E. F. W. Mackenzie and F. C. Hilton-Sergeant. *J. Roy. Army Med. Corps* **70**, 14–25, 73–81(1938); *U. S. Pub. Health Eng. Abstracts* **18**, W, 81(June 25, 1938).—Fecal *Escherichia coli* can be recovered more readily by the Eijkman test than by any other known method. C. R. Fellers

Typhoid fever from drinking water. Lomry. *Bruxelles-Med.* **18**, 344–52(1938); *U. S. Pub. Health Eng. Abstracts* **18**, W, 128 (Nov. 5, 1938).—The typhoid bacillus can live in ordinary pure water less than a month; paratyphoid bacteria can live up to 2 months under similar conditions. About 10% of the typhoid cases in Belgium are caused by drinking water. C. R. Fellers

Chlorinated copperas. F. O. Baldwin. *Water Works & Sewerage* **85**, No. 3, 197(1938); *U. S. Pub. Health Eng. Abstracts* **18**, W, 91(July 9, 1938).—In routine and exptl. lab. tests incident to flocculation control, it was found that freshly prepd. chlorinated $FeSO_4$ (copperas) soln. produces results more comparable with com. plant operations than when "stale" solns. were used. Such control requires an accurate, rapid and safe method of prepg. the chlorinated $FeSO_4$. The following procedure is recommended: Weigh out 1.195 g. copperas and wash it carefully into a 500-cc. aspirator bottle by means of a funnel with 200 cc. of distd. water. Connect the Cl cylinder by means of tubing to the bottle and add 36 cc. of Cl. Shake well. No color should be given by the soln. with *o*-tolidine reagent. Add 2 cc. more of Cl and shake well. Complete oxidation is usually obtained after the addn. of 38–39 cc. of the Cl. Dil. by washing and with distd. water to the 400-cc. mark on the bottle. One cc. of this soln. added to 500 cc. of water is equiv. to 50 lb. per million gallons on the plant scale. This strength of soln. hydrolyzes within 3 hrs. Stronger solns. are somewhat more stable. C. R. Fellers

Results of seven years' operation of the Soest sewage-treatment plant. Heinrich Blunk. *Gesungh.-Ing.* **62**, 323–30, 338–41(1939).—The plant originally consisted of settling basins with sep. sludge-digestion and open trickling units. The sludge-digestion chamber is heated and the sludge continuously stirred from the bottom up except for a brief period once a week when this direction is reversed. Fresh sludge is added daily. Measurements of gas evolution indicated that about a third of the org. matter in the fresh sludge is digested the first day, another third is digested within a few weeks, and the remaining third is practically nondigestible. At a digestion temp. of 27–8° about 21 cu. m. of gas is produced per cu. m. of sludge. The digested sludge is disposed of in the fluid condition for use as *fertilizer*. When the retention period was 2 hrs. the effluent from the settling basins seldom contained more than 0.2 cc. per l. of suspended solids. At a load of 1.2 cu. m. of sewage per cu. m. of filter material daily, the open trickling units operated satisfactorily even at a temp. of −10°, giving a nonseptic effluent having an O_2 content only 2–3 p. p. m. below satn. The $KMnO_4$ consumption was reduced from 200–400 p. p. m. to 50–100 p. p. m. by passage through these units. Increase in the amt. of sewage treated from about 2500 cu. m. per day to 6000–7000 cu. m. per day so far reduced the retention period in the settling basins that the effluent from them could not be satisfactorily purified in the open trickling units. These units were therefore enclosed and subsequent biol. treatment by means of activated sludge with aeration in a unit similar in construction to an Imhoff tank was added. The effluent from the trickling units is stable; the final plant effluent is entirely clear. The sludge from the final activated sludge unit differs in character from that obtained with sewage not previously biologically treated (in trickling units). This is also true of the flora and fauna present in the activated sludge unit. M. G. Moore

Effect of acidity of sewage on the behavior of bacterial filters. P.-G. Liègeois. *Rev. universelle mines* **15**, 597–9 (1939).—Bacterial reduction of sewage is conducted under anaerobic conditions. There are formed CO, CH_4, NH_3, H_2S and CO_2. Pathogenic bacteria are not destroyed by this method. The oxidizing method consists in complete aeration of the effluent; H_2O, CO_2 and mineral are formed. *Nitrosomonas* and *Nitrosococcus* convert amino N to nitrites and these are further converted to nitrates by *Nitrobacter*. L. finds that in several cases this oxidizing process was severely restricted or completely inhibited if the waste waters contained acid, e. g., dairy wastes. Expts. indicate that satisfactory operation of bacterial filters in such cases is possible only after neutralization of the acids, e. g., by filtration through calcareous material. M. Hartenheim

Removal of acid from water. Eric L. Holmes (to Permutit Co.). Can. 385,929, Dec. 26, 1939. Acid-contg. water is passed through a granular bed of a resin prepd. by the reaction of at least 1⅓ mols. of a monosaccharide, a disaccharide, or a substance that yields a monosaccharide or a disaccharide on hydrolysis, with 1 mol. of *m*-phenylenediamine or a 5-alkyl-*m*-phenylenediamine. The resin is regenerated by passing an alk. soln. through it.

Aerating tank for treatment of sewage by activated sludge. Karl Imhoff. U. S. 2,180,148, Nov. 14. Various details involving use of devices for mechanically agitating and also for spraying the liquid.

Apparatus for testing the rate of oxidation of sewage, etc. Carl H. Nordell (to Advance Engineering Co.). U. S. 2,180,847, Nov. 21. Various structural and operative details.

Pneumatic ejector plant suitable for raising liquids such as sewage. Harry Bentley (50% to W. C. Holmes & Co. Ltd.). U. S. 2,180,274, Nov. 14. There are used together a pair of ejector vessels, each having an inlet and an outlet, an air compressor of reversible type connected to the vessels to withdraw air from or deliver air to either vessel according to the direction of operation of the moving parts of the compressor, the air withdrawn from one vessel being delivered to the other vessel, and means responsive to liquid level conditions within the vessels for reversing the compressor.

Fuel gas from organic substances and wastes. László Zaitz. Hung. 122,564, Dec. 15, 1939. To org. matter contg. 90% moisture, at 25–8° and pH 7.2–7.8, in a closed container is added 5% of activated sludge. Tree leaves or other vegetable matter may be added. The mass is made alk. with $Ca(OH)_2$. The gases formed consist of easily purifiable methane. The sludge residue can be used as *fertilizer*.

15—SOILS, FERTILIZERS AND AGRICULTURAL POISONS

M. S. ANDERSON AND K. D. JACOB

Chemical work at soil-survey laboratory, Wellington. Anon. *New Zealand Dept. Sci. Ind. Research, Ann. Rept.* **13**, 59–60(1939).—Soils from the Kermadec Islands showed high fertility, were almost uniformly base-satd. and were fairly well supplied with plant foods. Cook Island soils also had a high content of available plant 6
food, almost complete base satn. and a slightly alk. reaction. The soils contained carbonate, possibly in the form of siderite. Some laterite soils from Western Samoa and Niue Island contained appreciable quantities of Cr. Neither Cr nor Ni in exchangeable form was found in soils from Western Samoa, Niue or Cook Islands, but a laterite soil from Siota, in the Solomon Islands, which is derived from serpentine rock and apparently is infertile, showed 7
appreciable amts. of both elements in this form. The nonexchangeable Cr in the Samoa and Niue soils seems to have no markedly toxic effect on plant growth.

K. D. Jacob

Some black soils of the Scioa (Ethiopia). Piero Belloni *Agr. coloniale* (Italy) **33**, 577–81(1939).—Analyses of 22 soils are tabulated. G. A. Bravo

Soils of Valdinievole. E. Lucchetti. *Ann. facoltà agrar. univ. Pisa* [N. S. 3rd.], **2**, 39–45(1939).—Complete 8
chem. and phys. analyses of 29 soils of the Lucca and Pistoia provinces are given. G. A. Bravo

Some microbiological examinations on reclaimed peat soils. G. Martelli. *Ann. facoltà agrar. univ. Pisa* [N. S. 3rd.], **2**, 28–31(1939).—Soils from the drainage of Massarosa (Lucca Province) show normal NH_3-producing power, slight N-fixing power, and no nitrification power.

G. A. Bravo 9

Microbiological investigation of the maremma soils collected between Lake Burano and Mount Fiora. G. Luchetti and R. Marcolini. *Ann. facoltà agrar. univ. Pisa* [N. S. 3rd.], **2**, 114–34(1939).—The max. no. of microörganisms was found in a calcareous soil (3,400,000 per g. soil), and the min. (200,000) in a clayey soil. The NH_3-producing power was max. in summer and in the clayey soils, the nitrification power was max. in autumn in the very loose soils, and the N-fixing power was max. in spring. 42 references. G. A. Bravo

The fertility of the soils of the East of Scotland area. A. M. Smith. *Scottish J. Agr.* **22**, 353–7(1939).—A survey of the soils showed 19% of the samples with pH values below 5.5 and 26% with values above 6.5. In 32% of the samples the lime requirement was more than 30 tons/acre and in 43% the requirement ranged from zero to 30 tons/acre. About 34% of the samples were low in available K (*Aspergillus niger* method) and about 23% were well supplied with this element. Deficiencies in available P (sol. in dil. HCl) were serious in about 23% of the samples, whereas about 32% contained adequate supplies of P.

K. D. Jacob

Chemical work at the Cawthron Institute. Theodore Rigg. *New Zealand Dept. Sci. Ind. Research, Ann. Rept.* **13**, 55–9(1939).—The leached condition of the topsoil and the presence of an Fe-humus pan at a depth of 12–20 in. are typical features of all pakihi soils at Westport. Podzolization is now taking place on the recent sands adjacent to the sea-beach at Sergeant's Hill and at other localities on the West Coast. Chem. analyses of the recent and older sands and of typical pakihi soil of the same textural type are tabulated. By means of the Bray method (cf. *C. A.* **24**, 453) soils could be rapidly classified into low-, medium- and high-P groups. By adoption of the following group limits for results by the standard citric acid method—namely, low, less than 0.02; medium, 0.02–0.04; high, greater than 0.04% P_2O_5 for 0–3 in. depths of soil—a good correlation was obtained for the results by the 2 methods for soils with a low P content. The correlation for soils in the medium and high groups was not so good, owing possibly to the influence of org. phosphates, which would be more sol. in citric acid soln. Detns. of K by Spurway's method (cf. *C. A.* **27**, 4004) gave results about ⅓ of those obtained by citric acid extn., but the correlation was sufficiently close to warrant the transposition of the results using this ratio. K. D. J.

Some applications of mineralogy to soil studies. Ann Nicholls. *J. Australian Inst. Agr. Sci.* **5**, 218–21(1939).

—A summary is given of a mineralogical study of a no. of Victorian soils. Such a study indicates: (1) the probable source of the soil-forming material, (2) the state of maturity of the soil, and (3) the fertility of the soil. J. R. Adams 1

The identification of minerals in soil colloids. G. Nagelschmidt. *J. Agr. Sci.* 29, 477–501(1939).—X-ray, optical, dehydration and chem. methods for the identification of minerals in soil colloids are discussed with special regard to their limitations. These are mainly due to uncertainties about the variation of phys. properties of standard minerals with decreasing grain size and the possible existence and importance of amorphous material. The aggregate method in x-ray analysis is described. Various techniques for dehydration and optical analysis are discussed, and it is concluded that they are useful only when used with x-ray data. The advantages of combining various chem. methods with x-ray analysis are pointed out. Standard data are given for quartz, cristobalite, oxides and hydroxides of Fe and Al and minerals of the kaolinite, montmorillonite and mica groups and the evidence for their occurrence in soil colloids is reviewed. Over 100 references are given. J. R. Adams 2

Pore space and apparent and true densities of soils. László Mados (Kotzmann). *Mezogazdasági Kutatások* 12, 205–9(1939).—The proportion of pore space was detd. in various samples originating from different layers of 13 soil profiles of different characteristics. Hygroscopic capacity was not found to be related to pore space or to true d. $P = 100(D_t - D_a)/D_t$, where D_t is true d. and D_a apparent d. The true densities of soils seem to be generally 2.6–2.7. The apparent densities ranged from 1.2 to 1.7, the values for pore space from 35 to 50% (detd. in summer time). For the calcn. of the removable soil water the formula $W = P - (4Hy + 12)D_a$ is recommended, where W is the amount of removable soil water, P the pore space, Hy the hygroscopic capacity and D_a the apparent d. of soil. S. S. de Finály 3

Suction force of the soil. Ruth Waeffler. *Botan. Centr., Beihefte* 59A, 275–334(1939).—Both soils and artificial substrates (as quartz, kaolin, Si carbide and C) showed with similar H_2O contents an increase of suction force with decreasing particle size. In pot culture, suction force decreased from the surface downward and from the outside, inward. Wetting of the upper soil layer gives rise to a temporary inversion; and the same change is noted with soils in the open after a rain. In drought the suction force of different soils increases at dissimilar rates. During the day there is more or less of a parallelity between suction force and satn. deficit of the surface layer of the soil to a depth of about 10 cm. R. C. Burrell 4

Technique of determination of the thermal parameters of soils in their natural state. V. Z. Bogomolov and A. F. Chudnovskiĭ. *J. Tech. Phys.* (U. S. S. R.) 9, 1325–30 (1939).—Measurements of *heat cond.* by the method of const. flow should not be used for soils, as the heat changes the humidity of the soil and, hence, its cond. To avoid this difficulty a metal plate, approx. 20 × 13 cm., is dipped into the ground; it is hot or is heated in position by an elec. current. The temp. of the ground opposite the center of the plate and about 2 cm. distant from it is recorded. The time when this temp. reaches its max. and the difference of temps. between the plate and the ground at another moment are sufficient to calc. the heat cond. and the vol. heat capacity of the ground. The product of heat cond. and heat capacity can be used for testing the humidity of grounds. J. J. Bikerman 5

Quick tests show southern soil needs. Frank Moser. *Better Crops with Plant Food* 23, No. 2, 11–13, 42–4(1939); cf. *C. A.* 33, 3942⁹.—A comparative study is made of the quick tests on some of the Piedmont and Coastal Plain soils of the cotton belt. The P tests are all based on the Deniges color reaction and the methods are satisfactory for diagnosing the P requirements of these soils. The Purdue and Bray methods tend to give consistently higher readings than the other methods. In general, the amts. of available P as shown by the rapid test methods are in accordance with the fertilizer treatments. The rapid test methods for detg. K_2O are modifications of the Na cobaltinitrite method and they are of approx. equal value for detg. K_2O in the soil. The differences in the replaced K in Cecil sandy clay loam and Orangeburg fine sandy loam as detd. by these methods are in agreement with the amts. added in a fertilizer. The rapid test methods for detg. available K_2O are suitable for soils contg. either a high or a low amt. of K_2O. Cf. B., *C. A.* 24, 453. J. R. Adams 6

Potentiometric determination of exchangeable hydrogen in unsaturated soils. Kenneth A. Maehl. *Ind. Eng. Chem., Anal. Ed.* 12, 24–7(1940).—The method used is similar to that described by Schollenberger and Dreibelbis (*C. A.* 24, 5407) except that the glass electrode is used for the potentiometric titrations. A small portion of the filtered ext. from 25 or 50 g. soil is used to obtain a voltage reading on the glass electrode. The mg. equiv. of H exchanged per 100 g. soil is then obtained directly from a curve which is constructed from data obtained on the cumulative rise in e. m. f. when a neutral soln. of NH_4OAc is titrated potentiometrically with AcOH. Thus, a single titration is sufficient for a large no. of samples. The glass electrode assembly and procedure are discussed. John O. Hardesty 7

Soil sterilization. W. S. Braintree. *Gardeners' Chronicle* [3], 103, 304–5(1938).—Formalin, phenol and toluene are discussed as soil disinfectants and a mixture of 11 parts of NH_4 carbonate to 1 part of Cu sulfate at the rate of 0.5 oz. per gallon of H_2O is recommended for combating damping off. Colin W. Whittaker 8

Soil solution as governed by H-ion concentration and other factors. A. T. Perkins. *Kansas Agr. Expt. Sta., 9th Biennial Rept.* 1938, 46.—Liming apparently increases the percentage of coarser particles at the expense of the smaller ones, and increases the percentage of the heavier minerals at the expense of the lighter minerals. C. R. Fellers 9

Soil acidity and liming, and some factors that should determine the standards for lime for the soil. Elmer O. Fippin. *Am. Soc. Testing Materials, Symposium on Lime* 1939, 56–70(1940).—A general review and discussion of the subject, including tests for need of lime, forms and fineness of limestone, rates of application and the use of ground raw dolomite or that selectively calcined to produce $CaCO_3.MgO$ as filler, conditioner or source of bases for mixed fertilizers. 121 references. C. J. S. 10

The occurrence of boron and manganese deficiencies in a sandy soil. Allan Walkley and H. K. Kemp. *J. Australian Inst. Agr. Sci.* 5, 229–30(1939).—Turnips, swedes and oats grown on a light-gray sand from McLaren Flat, South Australia showed symptoms of B deficiency, and the oats also developed symptoms of Mn deficiency when grown in the subsoil taken from this area. J. R. A. 11

Retention by soils of the nitrogen of urea and some related phenomena. John P. Conrad and C. N. Adams. *J. Am. Soc. Argon.* 32, 48–54(1940).—Untreated soils progressively removed at least some of the N of $CO(NH_2)_2$ and $CaCN_2$ from solns. as they percolated through them. This property was largely lost by percolating $CO(NH_2)_2$ at 90°, but persisted at 2, 11 and 40°. Two explanations for this retention of the urea N are offered: (1) a small amt. of adsorption by the soil of the $CO(NH_2)_2$ itself or (2) the transformation of $CO(NH_2)_2$ to $(NH_4)_2CO_3$ followed by the strong retention of the latter. Growth results with milo as well as the analyses of the small amt. of percolates from untreated columns, columns preheated to about 85° and columns in which percolation took place under toluene gave good evidence that the transformations of $CO(NH_2)_2$ in the soil, at least during the relatively short percolation time, was largely catalytic rather than microbial. J. R. Adams 12

The use of potash on Idaho soils. H. W. E. Larson. *Better Crops with Plant Food* 23, No. 7, 15–18, 42–5 (1939).—Peat and muck soils respond consistently to high K_2O-contg. complete fertilizers. No consistent results are obtained from K_2O fertilizers on cut-over soils. Southwestern Idaho mineral soils show more response to K_2O fertilizers than those in any other irrigated district. Quality and yield of truck crops are improved by the use of

fertilizers which contain K_2O. Alfalfa, beets, potatoes and peas show the greatest response to sol. phosphate alone or N plus P_2O_5 applications more consistently than they do to K_2O or K_2O plus P_2O_5 combinations. J. R. Adams

Phosphorus studies on Philippine soils. I. The readily available phosphorus of soils as determined by the Truog method. Ricardo T. Marfori. *Philippine J., Sci.* **70**, 133–42(1939); cf. *C. A.* **25**, 160.—Examn. of 90 soil samples, mostly rice soils of Luzon, showed that for some soil types about 30–40 p. p. m. of available P is the min. limit for a good crop of rice. When the total P content of the soil was const. the readily available P increased with increase in Ca content. When the Ca content remained const. the readily available P increased with increase in total P. Exceptions were with virgin soils rich in org. matter. Eighteen references. John O. Hardesty

Ammonification of dicyanodiamide and its derivatives in soil. H. Murata. *Trans. Third Comm. Intern. Soc. Soil Sci.* **A**, 137–9(1939).—Although dicyanodiamide (I) occasionally appears as a decompn. product of $CaCN_2$ in normally aerated soils and is considered injurious by preventing nitrification, it has some fertilizer value for paddy rice, which does not require nitrate. I is ammonified under waterlogged conditions; a low value for P_{O_2} (E_h less than 250 mv. at pH 7) and the presence of FeO or actively decompg. org. matter is favorable. Nevertheless, the practical value of I is not great, because it is not absorbed by the soil and is but slowly ammonified, so that it is likely to be lost in the drainage before it can be utilized. Guanyl urea, a deriv. of I, as sulfate or phosphate is an excellent fertilizer for paddy rice; the N is held by the soil even more firmly than NH_3, and it is ammonified under the same conditions as I. Eight references. C. J. S.

Tests on plant tissue as a guide to the soil's available nutrients. D. C. Wark. *J. Australian Inst. Agr. Sci.* **5**, 224–7(1939).—There is considerable variation in the nitrate N (I) and the P_2O_5 phosphorus (II) in certain localized areas of plant tissue. The level of these salts is influenced by the fertilizer treatment of the soil. The I tends to be highest in plants from the plots receiving the heaviest dressings of nitrogenous fertilizer and the II content is highest in plants receiving the heaviest dressings of superphosphate. With wheat, the I is higher in a fallow crop than in a stubble crop while the II is lower. Oats show a lower level of I but a higher level of P than barley. Peas show a very high level of II. During dull weather, when photosynthesis is reduced, the I content of the samples is higher than during bright sunshine. The test for N in plant tissues gives a reliable indication of the N status of the soil. J. R. Adams

The acidity of mulberry soils. I. The effect of acidity upon the absorption of nutrients by the mulberry tree. Husao Koyama and Tokusi Hukuta. *J. Sci. Soil Manure, Japan* **13**, 852–60(1939).—The growth and yield of the mulberry tree were max. in a plot of neutral reaction. The absorption of N, P_2O_5, K_2O and CaO by the plant was more intense in neutral than in acid soil, but the absorption of SiO_2 was the reverse. Y. Kamoshita

Effect of soil treatment on the vitamin B_1 content of wheat and barley. P. C. Leong. *Biochem. J.* **33**, 1397–9 (1939).—The observation of Harris (*C. A.* **28**, 6506[8]) that the vitamin B_1 potency of wheat was not influenced by soil treatment was confirmed. Similar results were obtained with barley. E. W. Scott

Smoke pollution [of soils]. H. Trefor Joues. *Agr. Progress* **16**, 224–9(1939).—A detn. of water-sol. sulfate is very useful in confirming or disproving cases of alleged smoke damage to crops and soils and in explaining differences in productivity of the various parts of affected fields. Treat 20 g. soil in a beaker with approx. 100 cc. hot water and stir for 5 min. Transfer the soil quantitatively to a filter paper, filter into a 500-cc. flask and wash the soil with hot water to a total vol. of nearly 500 cc. Cool the filtrate, dil. to 500 cc. and det. the sulfate as $BaSO_4$. If the ext. is brown and turbid add a few drops HCl and boil. Sulfate (SO_4) figures in excess of 0.02% for grassland and 0.03% for arable land indicate smoke pollution. Grassland soils northeast of Leeds contained 0.220, 0.184, 0.065, 0.051, 0.037, 0.022 and 0.020% sulfate (as SO_4) at distances of 0, 2, 3, 4, 7, 10 and 19 miles from the city, resp. K. D. Jacob

Root activity and the oxygen requirement in relation to soil fertility. Kenneth S. Karsten. *Am. J. Botany* **26**, 855–60(1939).—A method is described for detg. soil O_2 by the dropping-Hg electrode. The O_2 content of soils varied with soil type, water, N and org. matter content. The O_2 content is less than expected on the basis of pore space because of the respiration of soil microörganisms. Addn. of N and org. matter increases microbiol. activity and growth; this decreases the O_2 content of the soil. If the O_2 content is sufficiently reduced, root activity is decreased and the entire plant is affected. N. McK., Jr.

The nitrogen nutrition and growth of certain deciduous trees of northeastern United States. Harold L. Mitchell and Robert F. Chandler, Jr. *Black Rock Forest Bull.* No. 11, 94 pp.(1939).—Series of from 3 to 6 quarter-acre plots were established in stands of mixed hardwoods on each of 6 different sites. One plot of each series served as a control and the others were supplied with varying amts. of nitrogenous fertilizer (a mixt. of equal wts. of $NaNO_3$ and $(NH_4)_2SO_4$). Near the end of the same growing season that the fertilizer was applied, leaf samples for chem. analysis were taken from dominant and codominant trees on each plot. The av. radial increment of trees on the variously fertilized plots was detd. by means of increment borings. Both the growth and the foliage-N content of the trees increased with N supplements through a range of N supplies equiv. in effect to those of poor to good natural soils. Further addns. of N resulted in successively smaller increases in radial increment and leaf-N concn. These relationships could be expressed algebraically with the Mitscherlich formula. On the fertilized plots the leaves of all species were 30–150% greater in size and much darker green in color than those of trees on the control plots. Red, white and chestnut oaks, red maple and aspen made fairly satisfactory growth in N-deficient soils and approached max. radial increment at a significantly lower relative N supply than any of the other trees studied. Beech, sugar maple, pignut hickory and black gum appeared to be intermediate in the scale of N-deficiency tolerance. Yellow poplar, white ash and basswood made poor growth in N-deficient soils and approached max. growth only at very high levels of N availability. There was a high degree of correlation between tree growth and leaf-N concn. The ability of the N-deficiency-tolerant species to sustain growth in soils of low N availability is attributed to the fact that, on such sites, the leaf-N concn. of these trees is significantly greater, in relation to their resp. optima, than for the intermediate or N-demanding species. With the method of foliar diagnosis, detns. of the relative N-supplying capacities of 50 representative forest sites throughout the northeastern United States indicated that 20% are N-deficient and only 15% have a high N supply. Inspection of stands on sites thus evaluated revealed not only a growth relationship but a high degree of correlation between soil-N supply and the frequency of incidence of the N-requiring species. As with N, there was a good correlation between the amts. of P and K applied to the soil and the concns. of these elements in the leaves of the trees studied. Thirty-one references. K. D. Jacob

Experimental studies at Ohio State University in ornamental horticulture during 1938. L. C. Chadwick and D. C. Kiplinger. *Trans. Iowa State Hort. Soc.* **73**, 167–71 (1938).—In soil adjusted to pH values of 5.0–8.0, the best yields of blooms from *rose bushes* were obtained at pH 5.0. On soils of pH 5.0–5.5, the response of roses to applications of Zn salts was greater than that to applications of Mn, Mg or B compds. (0.5–1.0 lb. per 50 sq. ft.). Treatment of rose bushes with Bordeaux mixt. before storage had no beneficial effect on the survival of the bushes when they were subsequently planted. Practically complete *control of weeds in potting soil* was obtained by treating the soil in covered boxes with chloropicrin (3 cc. or more per sq. ft.). Remove the covers after 4 days, turn or shred the soil to hasten aeration and allow all traces of the gas to

leave the soil (usually after 10–14 days) before it is used for planting. The best results are obtained when the soil temp. is at least 45.5°F. and the moisture content is 50–60% of the water-holding capacity. Compost heaps should be treated with 5–10 cc. chloropicrin per cu. ft. K. D. Jacob

The occurrence in soil of bacteria, actinomycetes and molds capable of transforming tyrosine to melanin or other pigments. Charles E. Skinner. *Trans. Third Comm. Intern. Soc. Soil Sci.* A, 130–2(1939).—Plating on Conn's Na asparaginate glucose agar with 0.1% tyrosine, etc., indicated that organisms of these genera, alike in producing red or black pigments, are very common and numerous in soils. The black pigment or melanin is sol. in weak alkali, pptd. by acids, insol. in EtOH and Et_2O but disperses in EtOH and H_2O. It is believed to be identical with the "humic acid" of various investigators. The red pigment changes quickly to the black when heated with weak NaOH soln., and appears to be the precursor in all cases; not all organisms produce the enzyme effecting the transformation, and with some the red pigment remains unchanged, or alters only very slowly to brown. The pigments are produced only by oxidation from tyrosine and in a few cases from phenylalanine, which have been shown to be produced from both inorg. and org. N by many organisms, and it is suggested that this is the source of "humic acid." C. J. Schollenberger

Microbial activity in relation to organic matter transformations in the soil. S. C. Vandecaveye. *Trans. Third Comm. Intern. Soc. Soil Sci.* A, 120–9(1939).—Samples from horizons *A* and *B* of 15 virgin soils of 5 genetic groups and 0–8- or 10-in. samples of the same under cultivation, alone and with 1–2% ground sweet clover hay or wheat straw with a N carrier to total 3% N in the addn., were incubated at 22–28° for detg. CO_2 production, microbial counts and proximate analyses for org. constituents by the methods of Waksman and Stevens (*C. A.* 24, 2965), total C and N and pH. Microbial counts were also made on samples of the same soils direct from the field at intervals. The effects of the addns. upon the microflora varied with the soils—in some, bacteria were stimulated, in others repressed relative to other species. These differences are attributed mainly to differences in the soil humus. The proximate analyses indicated that a high content of H_2SO_4-sol. C and N, cellulose, hemicellulose and proteins was assocd. with a heavy growth of *Actinomyces*, although these did not reach their max. until bacteria and fungi had consumed the H_2O-sol. C and N and declined. A low C/N in some soils was accompanied by a predominance of bacteria and relative scarcity of fungi, although there were exceptions. Conclusion: Data from proximate analyses alone are insufficient to explain the differences in microbial activity observed. Eleven references. C. J. Schollenberger

The influence of reaction on the development of an acid-tolerant Azotobacter. Robert L. Starkey. *Trans. Third Comm. Intern. Soc. Soil Sci.* A, 142–50(1939).—It is generally accepted that *Azotobacter vinelandii* (I) does not fix N at pH values below 6; if I develops in soils more acid, combined N is utilized. *Azotobacter indicum* (II) was isolated by Starkey and De (*C. A.* 33, 6385[3]) from Indian rice soils at pH 4.9–5.2. Differences in the morphology of I and II are briefly discussed. Expts. on development and behavior under lab. conditions are described. II can develop on solid or in liquid media contg. no fixed N, from about pH 3 to 9; much slime is produced, watery on alk. and very tenacious on acid agar, showing a buff color above and colorless below pH 6. Acidity generally increases as growth progresses, especially when NH_4 salts are present, but if nitrate is present there may be a tendency toward alky. N in both forms is utilized and urea is hydrolyzed to NH_3, but urea is unfavorable to growth. N fixation is inhibited by these N compds. $CaCO_3$ in media has an unfavorable effect upon the growth of II. Eighteen references. C. J. Schollenberger

The utilization of phenolic compounds as a source of energy by Azotobacter of the soil. G. Guittonneau and R. Chevalier. *Trans. Third Comm. Intern. Soc. Soil Sci.* A, 161–7(1939)(in French); cf. *C. A.* 32, 4188[6].—Expts. with pure cultures of *Azotobacter* and suspensions of soils plated on SiO_2 gel contg. either mannitol (I), the Na salt of BzOH (II), salicylic (III), *o*-(IV), *m*-(V) or *p*-(VI) hydroxybenzoic acids or PhOH (VII) as the source of C, in all cases adjusted to neutrality and incubated 15 hrs. at 30° for colony counts, indicated that the benzene nucleus and phenolic groups are utilized as sources of energy by *Azotobacter*. This has long been known with respect to II, but not of the other related compds. Tests with suspensions from different soils comparing 2 g. I with different concns. of III indicated that 0.125–0.25 g./200 ml. medium was second best, although in all cases much inferior to I, and varying with the soil used. 0.1–0.5 g. of II, IV and VI gave about the same no. of colonies, but none appeared when the same amts. of V were used; other expts. indicated that V is not toxic, but simply is not utilized as a source of energy and it is suggested that this is dependent upon some peculiarity in mol. structure. 0.05–0.1 g. of VII gave about the same nos. of colonies; 0.2 g. was very toxic. The fixation of N observed in some expts. was about 75% as great with III as with I, figured on equal wts.; the abs. amt. of N fixed was about 1% of I consumed. The expts. so far have indicated the presence of 5 strains or classes of *Azotobacter* in the soils tested, which can be distinguished by their ability to grow with these substances as the sole sources of energy. The optimum concns. and conditions recommended for purifying and distinguishing *Azotobacter* strains by this means are specified. C. J. Schollenberger

The nature and amount of extracellular nitrogen in Azotobacter cultures. C. Kenneth Horner and Dean Burk. *Trans. Third Comm. Intern. Soc. Soil Sci.* A, 168–74(1939).—The results of an extensive investigation on the extracellular N compds. produced by *Azotobacter* are summarized. On the new synthetic N-free media, concns. of 25–50 mg. N/100 ml. are easily obtained. Some 20 strains of *Azotobacter*, including *chroöcoccum* (I), *vinelandii* (II), *agilis* and *agilis* var. *atypica*, are included. In 1–4-day cultures, 10–25% of the total N was sol. and extracellular; at 1–3 weeks this increased to 50–75% of the total N. The increase was largely due to autolysis, but even in the youngest cultures much of the sol. N is a normal vital secretion. Virtually all the N secreted is org. and amounts to 10 3% of the org. C liberated, slightly less than the C/N of the cells themselves. Pptn. reactions of the sol. N indicated it to be very heterogeneous, of simple to complex proteinaceous nature. In a 2-day culture, the N was 75% dialyzable through cellophane, permitting the passage of N compds. of mol. wt. 6000–10,000; the proportion was somewhat less in old cultures. The growth and N fixation of cultures in cellophane bags were not affected by continuous removal of the excreted N, by dialysis into medium outside. Amino N was detected regularly when the total N fixed exceeded 5 mg./100 ml. and increased to 1–2 mg./100 ml. but decreased from 10–40 to 5–15% of the total with age. A considerable part of the N in one old culture was dicarboxylic acid amino N, but amino N in general was not predominant; so far as *Azotobacter* is concerned, there is no proof that aspartic acid is specifically an intermediate in N fixation. NH_3 was not found until all sugar had been consumed and autolysis had set in, and the max. found in this later work with undoubtedly pure cultures was 12% of the total N, compared with 50% reported previously, from cultures now believed to have been contaminated; the former figure is in line with findings by others. It is certain that exhaustion of the sugar supply is a prerequisite for NH_3 accumulation, and NH_3 is not proved to be an intermediate in N fixation by *Azotobacter*. Nitrite was found only in cultures supplied with nitrate; up to 0.05 p. p. m. NH_2OH was detected only in cultures of II and small amts. of oxime N were found quite regularly with some strains of I. Factors which increased growth of the organisms, e. g., supplying Mo when deficient, also increased the production of sol. N; it increased 2–3 fold when combined N was supplied, more with org. N than with inorg. N. Conclusion: $^1/_6$–$^1/_3$ of the N fixed by *Azoto-*

bacter can be liberated again as sol. org. N; in pure cultures, only 10% of the N fixed will be released as NH_3. Five references. C. J. Schollenberger

Studies on Azotobacter and nitrifying organisms in relation to various fertilizer treatments in soils under citrus culture conditions. M. Winnik and Miriam Goldberg. *Trans. Third Comm. Intern. Soc. Soil Sci.* A, 175–83(1939).—Microbiol. studies of poor red sandy loams in lysimeters under irrigated citrus culture, some with lupines as a green manure crop, with the SiO_2-gel plating technique of Winogradsky, with kneaded earth plates for detg. *Azotobacter* activity and P_2O_5 deficiency, are reported. It is concluded that supplying the usual fertilizers, including about 1 kg. N/tree in green manure during the 9-yr. expt., definitely decreased the activity of *Azotobacter*. N alone was more repressive than when P_2O_5 and K_2O also were supplied, and in nitrate than in green manure. There were no tests with minerals alone, without N. $(NH_4)_2SO_4$ was injurious to *Azotobacter*, even with P_2O_5, K_2O and green manure, probably because it reduced the $CaCO_3$ of the soil and caused a temporary reduction of pH from 7.4 to 6.7. $NaNO_3$ was somewhat less repressive than the other mineral N carriers, probably because it caused a slight increase in available P_2O_5, as shown by analyses. All fertilizers, including nitrates, increased the activity of nitrifiers; the effect of green manure was notable, and $(NH_4)_2SO_4$ stimulated nitrification more than nitrates did. The activity of the latter is attributed to increased available P_2O_5. It is concluded from other data that when the P_2O_5 supply is adequate, N fertilizers will have less unfavorable effect upon *Azotobacter*. Four references. C. J. Schollenberger

The effect of benzoic acid compounds on the abundance of microörganisms, including Azotobacter organisms, in a soil. Herbert W. Reuszer. *Trans. Third Comm. Intern. Soc. Soil Sci.* A, 151–60(1939); cf. *C. A.* **32**, 9156[1].—BzOH or its Ca or Na salts were added to a soil, 1, 2.5 and 5% dry wt., moistened to 20% and incubated for 1–15 weeks at 28°. Samples were examd. for pH and nitrate contents, bacteria, *Actinomyces*, mold fungi and *Azotobacter* counts on plates with the usual media. Addns. of BzOH initially lowered pH from the original figure 7.4 to about 6, but after 1 week the soil mixts. varied from pH 7 to 8, approx. in line with the size of the addn. BzONa had but a slight effect initially, but caused rapid rise to max. pH 10 with the largest addn., 9 and 8.5 with the others; the Ca salt had slight effects, probably from its lower soly., and not consistent with the foregoing, although pH was raised. Nos. of organisms were increased most rapidly by the smaller addns., but the larger amt. of BzONa had a repressive effect attributed to high pH. The variety of organisms was reduced, especially by the larger addns. The larger addns. of BzOH and BzONa caused the appearance of a strain of *Azotobacter* producing green pigment, never before observed; the fact that this appeared only after 3–5 weeks and that its growth seems actually to be favored by high concns. of BzONa is taken as evidence that it is a rare form originally present. It is believed that cultivation upon media contg. BzOH may prove of value in studying *Azotobacter*. Five references. C. J. S.

Respiration rates of Rhizobium; their estimation and significance. Franklin E. Allison and Sam R. Hoover. *Trans. Third Comm. Intern. Soc. Soil Sci.* A, 32–38 (1939).—Expressed as Q_{O_2}, (cu. mm. O_2 consumed/mg. dry wt. organisms/hr.), the respiration rates of alfalfa and clover bacteria are 5–40 in presence of glucose. For most other bacteria, Q_{O_2} does not exceed 200, although *Azotobacter* may show the exceptionally high value 5000. With *Rhizobium*, Q_{O_2} at 28° is usually 5–8, the higher value with young cultures. In the absence of substrate, rates of 2–5 were maintained by endogenous respiration; values above 8 indicate growth or assimilation. Coenzyme *R* is essential for respiration and growth, but increases respiration only under conditions permitting subsequent growth, indicating interrelated effects. The resting cell technique for measuring substrate oxidation is rather unsatisfactory with truly resting *Rhizobium*, because Q_{O_2} is low with or without substrate; it is sometimes useful with actively assimilating and proliferating cells, but the results then represent both substrate oxidation and growth. A resting cell must be defined as one both nonproliferating and nonassimilating. Fifteen references. C. J. S.

Symbiotic nitrogen fixation. W. W. Umbreit and P. W. Wilson. *Trans. Third Comm. Intern. Soc. Soil Sci.* A, 29–31(1939).—The status of the problem is reviewed, with the conclusion that the classical methods of org. investigation do not offer much promise of aiding its solution, but studies of the enzymes concerned and the influence of variations in pN_2, pO_2 and pH_2 may be more useful. Red clover inoculated with an efficient strain of *Rh. trifolii* and kept under different values for pN_2 fixed N in proportion thereto up to 0.15 atm.; above that point there was no difference in fixation. pO_2 had little direct influence, and it is believed that O_2 is important in N fixation only indirectly through its effect upon carbohydrate metabolism of the host plant. H_2 has an inhibiting effect proportional to pH_2, but does not affect the growth of clover supplied with combined N, nor nonsymbiotic fixation of N by *Azotobacter*. Argon and He had no effect upon N fixation by clover. The specific effects of H_2 upon symbiotic N fixation promise a means for distinguishing N-fixation reactions from those involved in other phases of N metabolism. Eleven references. C. J. Schollenberger

Symbiotic nitrogen fixation by leguminous plants. Artturi I. Virtanen. *Trans. Third Comm. Intern. Soc. Soil Sci.* A, 4–19(1939); cf. *C. A.* **32**, 7958[7]; **33**, 3950[8], 7024[6].—A description of the technique of expts. proving that legume seedlings in sterile cultures grow best when N is supplied as *l*-aspartic acid (I) rather than inorg. salts. Glutamic acid was a fair source of N, but no other amino acid was well utilized. Similar expts. showed that cereal seedlings were unable to utilize amino acids directly. Inoculated legumes grown in otherwise sterile sand or cellulose excrete much more combined N than in H_2O cultures, because the solids adsorb the excreted products, which can then be extd. almost quantitatively by H_2SO_4 or HCl at pH 4. 90–98% of this N was in α-amino acids; α-aminomonocarboxylic and aromatic amino acids were absent. About 50% of the N excreted by inoculated peas harvested at flowering was in I; no glutamic acid was found, but the remaining amino N was in β-alanine, considered a decompn. product of I. These excreted N compds. are not products of protein breakdown, but I is the primary product of the biol. fixation of N and is taken up by the host plant from the nodules. In studies of the mechanism of N fixation, exptl. proof of fixation of N_2 from air by excised root nodules in a dil. neutralized soln. of oxaloacetic acid (II) was obtained; the results were checked by Kjeldahl detns. and are interpreted as evidence of the central position of II in biol. N fixation; II was demonstrated in legumes during the period of active N fixation but not later. The synthesis of amino acids in plants supplied with nitrate or NH_4 salts is briefly discussed in the light of the foregoing. A reply to Wilson (*C. A.* **33**, 5971[1]) is appended. C. J. Schollenberger

Some soil factors in nitrogen fixation by legumes. Wm. A. Albrecht. *Trans. Third Comm. Intern. Soc. Soil Sci.* A, 71–84(1939).—From studies on total growth, N fixation and compn. of soybeans grown on a medium of quartz sand and electrodialyzed beidellite clay (T = 65 millicquiv./100 g.) satd. to different degrees with Ca, with H, Ba, Mg or K as the other cation, it is concluded: N fixation and growth are directly related to Ca satn., although addnl. Ca supplied in a larger amt. of clay at the same degree of satn. also caused increases. Similar results were obtained whether H or Ba was the other cation, provided pH exceeded 5.5, the isoelec. point for soybean plants; below pH 5.5, no Ca could enter the plants, there was little growth and no N fixation, while at higher pH values, Ca supply was the principal factor and pH was important only as it was related thereto. In other expts., methylene blue, an org. cation of high mol. wt., was added to the colloidal clay-sand mixt. to simulate org. matter in a clay soil. Ca utilization and N fixation were high and independent of the level of Ca satn., suggesting that the

org. cation displaced H from the clay and was itself so firmly held that the release of Ca was facilitated. At low levels of Ca satn., P_2O_5 in the seed was lost to the substrate and there was little growth and no N fixation in 6 weeks. When 0.2 milliequiv. Ca was supplied for each plant, all P_2O_5 was retained and there was good growth and fixation in that time. Mg seems not to be directly active in N fixation, but increases the activity of Ca; without Mg, there was no N fixation when the plant tissues contained less than 0.50–0.55% Ca, when Mg was supplied fixation was marked with 0.45% Ca. K showed an antagonistic effect toward Ca; there was much less N fixation and the plants contained less Ca but more K when the latter partly replaced Ca in the clay. With the relative excess of K, the C/N in dry matter was widened. It is suggested that the loss of Ca and relative increase in active K during soil development may account for changes in flora and decrease in tendency to accumulate N and org. matter. Six references. C. J. Schollenberger

Direct estimation of biological nitrogen fixation. A gasometric method. Charles Hurwitz and P. W. Wilson. *Ind. Eng. Chem., Anal. Ed.* **12**, 31–3(1940).—A method is described for the detection of uptake of free N by biol. agents which is based on the principle of quantitatively replacing N fixed, as well as O respired, with O of known purity. Tests with *Azotobacter* cultures indicate that it is reliable and reasonably accurate. Its advantages over Kjeldahl methods for use with heterogeneous substrates, as seeds and plant tissues which are initially high in org. N, are discussed. John O. Hardesty

Minor element fertilization of horticultural crops. F. S. Jamison. *Better Crops with Plant Food* **23**, No. 7, 19, 39–42(1939).—A discussion is given of the use of minor elements in fertilizers for raising horticultural crops and overcoming nutritional deficiencies. J. R. Adams

The influence of fertilizer treatment on the carotene content of poor pasture grass, and on the relation of this constituent to the ash and organic fractions. F. E. Moon. *J. Agr. Sci.* **29**, 524–43(1939); cf. *C. A.* **32**, 8661⁷.—$(NH_4)_2SO_4$ and $NaNO_3$, applied at monthly intervals, increased the carotene content of poor pasture grass by 28%. Monthly applications of K_2SO_4 produced an increase of 6.2%. A single dressing of $CaCO_3$, enough to satisfy the CaO requirement of the soil, produced no effect on carotene content, while monthly dressings of superphosphate also had no influence except in June, when an increase of 14.5% was produced. All 5 treatments significantly increased the yields of dry matter and carotene. Marked seasonal variations in the carotene contents were noted. Ash content was increased by the 3 nonnitrogenous fertilizers, protein content by $NaNO_3$, $(NH_4)_2SO_4$ and superphosphate, ether ext. by superphosphate and $(NH_4)_2SO_4$, while N-free ext. was decreased under all but the $CaCO_3$ treatment. None of the 5 fertilizers had any effect on the mean fiber content of the grass. Correlations of carotene with crude protein, fiber, N-free ext. and ash were computed for each fertilizer treatment and several significant differences were observed. J. R. Adams

Results of continuous fertilizer experiments on the experimental plots of the Agricultural Experiment Station, Berlin-Lichterfelde. A. Jacob and R. Gottwick. *Ernähr. Pflanze* **36**, 1–8(1940).—Expts. were carried out from 1930 to 1936 with potatoes, winter rye, lupines, beets, winter wheat, oats and maize grown on sandy soil and receiving different fertilizer treatments as follows: control; N in conjunction with P; complete fertilizer with K in different forms, namely, $K_2Mg(SO_4)_2$, K_2SO_4, kainite, 40% manure salts and KCl. The beneficial action of K on yields was slight during the 1st yr. but increased each year thereafter with $K_2Mg(SO_4)_2$ giving best results. No change occurred in the mineral contents of the fertilized plants except that the K content of straw and foliage was higher in the plants receiving high amts. of K_2O. John O. Hardesty

Cotton fertilizer tests on two valley soils. I. E. Miles and Russell Coleman. *Better Crops with Plant Food* **23**, No. 4, 11–14, 43–5(1939).—Most of the bottom soils of Mississippi, as represented by Lintonia silt loam and Ocklockonee fine sandy loam, show a K_2O deficiency. J. R. Adams

Fertilizing tomatoes in eastern Virginia. E. R. Purvis and J. M. Blume. *Better Crops with Plant Food* **23**, No. 9, 19–21, 40(1939).—N and K_2O are essential to the early growth of tomatoes and should be applied before setting on soils of low fertility. Many of the old agricultural soils of Virginia are in need of CaO. J. R. A.

How to prevent fertilizer burn. Wm. H. Ross and Lawrence M. White. *Better Crops with Plant Food* **23**, No. 1, 21–2, 45–7(1939).—The burning effects of excessive applications of fertilizer mixts. of the ordinary type may be considered as roughly proportional to their effect on the concn. of the soil soln. Other factors, such as the nonfertilizing sol. salts, being the same, an increase in the plant-food content of a sol. fertilizer material tends to decrease its burning effect. The arrangement in ascending order of the tendency per unit of total plant food value of different fertilizer materials to change the concn. of soil soln. is as follows: double superphosphate, $NH_4H_2PO_4$, superphosphate, NH_3, cottonseed meal, K_2SO_4, KNO_3, $CO(NH_2)_2$, KCl, NH_4NO_3, $(NH_4)_2SO_4$, manure salt, $NaNO_3$ and kainite. Burning from the use of fertilizer mixts. is decreasing because of the use of synthetic products. Contributing factors are the replacement of kainite and low-grade K_2O salts with high-grade KCl or K_2SO_4, the substitution in part of free NH_3 and $CO(NH_2)_2$ for other sol. nitrogenous materials and the need of less fertilizer per acre because of the increased plant food content of the mixts. Burning of crops is also being reduced by improved methods of application. J. R. Adams

Availability of the natural phosphates. A. A. Sanfourche and B. Tallibart. *Compt. rend. acad. agr. France* **25**, 953–9(1939).—Availability tests of the P_2O_5 of superphosphate and crude phosphate rock in soils of pH 7.5, 7.3, 6 and 5 show that the P_2O_5 of the superphosphate is more available than that of the rock in all but the most acid soil. In this soil the 2 sources of P_2O_5 show the same P_2O_5 availability. J. R. Adams

New calcined phosphates. Hans Huber. *Chem.-Ztg.* **64**, 22–4(1940).—A review of recent work on fertilizers made from rock phosphate by calcination; 25 references. E. H.

Reasons for the P_2O_5 in phosphorite being more available to plants after chlorination. V. V. Butkevich, A. A. Germanov and K. I. Gadalova. *Compt. rend. acad. sci. U. R. S. S.* **24**, 574–6(1939)(in English).—Expts. show that about 33% (the most active part) of the $CaCO_3$ in phosphorite is destroyed by Cl. As a result of chlorination this hydrolytically alk. salt is converted into $CaCl_2$. The CO_2 is therefore no longer apt to cause the formation of $CaCO_3$ in the soln. Chlorination of phosphorite made its aq. ext. (1:5) change its pH from 6.5–7.0 to 3–3.5. The acidity of this ext. as detd. by titration against phenolphthalein became 100–240 cc. of the 0.1 *N* $Ba(OH)_2$ per 100 g. of chlorinated phosphorite. This increase in acidity of the phosphorite meal has a pos. influence on the availability of the P_2O_5 in phosphorite to plants. HCl can be used instead of Cl applied in the form of exothermic chlorination. 14 references. A. H. Krappe

Potassium metaphosphate—a potential high-analysis fertilizer material. S. L. Madorsky and K. G. Clark. *Ind. Eng. Chem.* **32**, 244–8(1940).—Prepn. of KPO_3 from KCl and H_3PO_4 was studied over the temp. range 300–900°. Products obtained at 700° or above were practically H_2O-insol., nonhygroscopic and contained relatively little free acid and unreacted KCl. Chem. analyses and vegetative tests showed that the K and P in KPO_3 are available to plants. Methods were developed for directly *detg. meta- and pyrophosphates in the presence of orthophosphate.* Phys. properties and the economic advantages of KPO_3 as a fertilizer are discussed. John O. Hardesty

Fluoride-induced reversion in mixtures of superphosphates and calcined rock phosphate. W. H. MacIntire and L. J. Hardin. *Ind. Eng. Chem.* **32**, 88–94(1940); cf. *C. A.* **32**, 3537⁷.—Analytical results showed that the development of citrate-insol. P_2O_5 in mixts. of super-

phosphate and calcined phosphate is due to the formation of fluorphosphate, chiefly through the reaction between component fluorides and $Ca_3(PO_4)_2$. The resulting phosphate-fluoride compd. is similar to the native phosphorite of raw rock phosphate but decidedly more available to plants. Defluorinated phosphate can be mixed with fluoride-free superphosphates in any proportion without loss of available P_2O_5. John O. Hardesty

The biological action of boric acid. E. Lucchetti. *Ann. facoltà agrar. univ. Pisa* [N.S. 3rd], **2**, 304–36 (1939).—In the action of B on the microörganisms, on the biochem. and enzymic activity of the soils, and as a fertilizer, there is a stimulating and a toxic concn. It is doubtful if B is indispensable for plants, but it can modify their functional activity. 50 references. G. A. Bravo

Shallow-soil orchards respond to potash. J. R. Van Haarlem and G. H. Dickson. *Better Crops with Plant Food* **23**, No. 1, 6–8, 41–2(1939).—Leaf scorch of apple trees, probably due to a K_2O deficiency in the Vineland fine sandy loam, was remedied by the use of a K or a K-P fertilizer. The fertilizers used were KCl and superphosphate. The use of K fertilizer caused a much greater tree growth over a period of 5 yrs. than did either P or K-P fertilizers. Some of the wide differences between the results on the K and K-P plots were due to the deeper and better texture soil in the K-P plots. J. R. Adams

The effect of potash upon the yield, size and carbohydrate accumulation of potato tubers. Tomota Sugawara. *J. Sci. Soil Manure, Japan* **13**, 829–39(1939).—In plants deficient in potash the leaves became dark green, then yellowish brown at their edge, gradually curled down and finally dried up. Increase of potash supply caused no marked effect on the ratio of length to diam. of tubers but had a beneficial effect on the size and yield of tubers. Starch accumulation in tubers was increased by heavy application of potash and was lowered by potash starvation. The growth of tubers and also of their starch grain was directly proportional to the amount of potash added to the soil. Y. Kamoshita

Garden uses of potassium permanganate. John Derbyshire. *Gardeners' Chronicle* [3], **105**, 220(1939).—Periodic sprinkling of each cu. yard of a compost pile with 6 gallons of a soln. contg. 3 oz. of $KMnO_4$ increased the rate of decomposition. Other agricultural uses of $KMnO_4$ are discussed. Colin W. Whittaker

Growth and quality of sugar-beet root as influenced by periodical supply of nitrogen and potassium. I. V. Gulyakin. *Compt. rend. acad. sci. U. R. S. S.* **24**, 712–15 (1939) (in English).—Previous expts. (cf. *C. A.* **33**, 6502[7]) were continued and Hellriegel's nutrient mixt. was applied as before; it was shown that high amts. of N are absorbed by the plant during leafage. When subsequently intensive root growth and sugar storage are taking place, the N requirements are considerably reduced. If the sugar beet is given less N at that time, the protein breakdown in the aging leaf is accelerated; within limits it has a pos. effect on the root yield. With too rapid a breakdown of the proteins the leaves die away prematurely and the root weight is decreased. Leaf growth is also detd. by a supply of K, a deficiency of which eventually reduces the root weight. 5 references. A. H. Krappe

Fluctuation in the nitrogen content of cereal grains. P. Boischot and J. Herviaux. *Compt. rend. acad. agr. France* **25**, 944–9(1939).—The N enrichment of the soil by the commonly used fertilizers caused no marked variation in the N content of the grain. This was true in the case of each of the 3 fertilizers tested. J. R. Adams

Action of arsenic salts on the microflora of the soil. R. Perotti and O. Verona. *Ann. facoltà agrar. univ. Pisa* [N. S. 3rd], **2**, 32–8(1939).—The action of As salts (Na arsenites, etc.) on the microörganisms of the soils was examd. in the course of arsenical treatments for destroying *Cuscuta* in alfalfa and clover. An occasional transient decrease in NH_3-producing and nitrification powers was observed; probably As ions do not accumulate in the soils, but are removed by microörganisms and converted to volatile compds. G. A. Bravo

Toxic limits of replaceable zinc to corn and cowpeas grown on three Florida soils. O. E. Gall and R. M. Barnette. *J. Am. Soc. Agron.* **32**, 23–32(1940).—The toxic limits in milliequivs. per 100 g. of soil of replaceable Zn for corn were 0.688 and 1.376 on a Norfolk sand, 0.758 and 1.137 on an Orangeburg fine sandy loam and 1.615 and 2.153 on a Greenville clay loam. The corresponding figures for cowpeas were 0.275 and 0.482, 0.379 and 0.758 and 0.538 and 1.077. The application of $Ca(H_2PO_4)_2$ at the rate of 233 lb. per acre to the Norfolk sand and 1800 lb. per acre to the Orangeburg fine sandy loam and Greenville clay loam did not change the toxic limits of the replaceable Zn for corn or cowpeas. The presence of P_2O_5 as a plant nutrient, however, stimulated the growth of corn and cowpeas on the Orangeburg and Greenville soils, while no effect was noted on the Norfolk sand. The use of $CaCO_3$ at the rate of 1000 lb. per acre on the Norfolk sand and 4000 lb. per acre on the other 2 soils definitely increased the concns. at which replaceable Zn became injurious to corn and cowpeas and greatly alleviated the toxic condition. J. R. Adams

Organic and inorganic fertilizers; their relative effectiveness. E. John Russell. *Scottish J. Agr.* **22**, 319–31 (1939).—There is no definite evidence that farmyard manure and other org. fertilizers are superior to equiv. quantities of inorg. fertilizers in increasing the yields and improving the quality of crops. Farmyard manure and composts are of particular value in supplying humus to the soil and improving its phys. properties. K. D. Jacob

The manufacture, composition and action of bone meal for fertilizer and stock food. O. Engels. *Knochenverarb. u. Leim* **1**, 43–9, 75–8(1939).—A review with 10 references. Don Brouse

Brazilian raw material for phosphatic fertilizers. L. F. de Moraes Rego. *Mineracão e met.* (Rio de Janeiro) **2**, No. 12(1938); *Neues Jahrb. Mineral. Geol.* Ref. II, **1938**, 656.—The most hopeful deposit is at Ipanema in São Paulo, where a bed of apatite in the hydrothermal phase of a nephelite-rich magma contains on an av. 10–15% apatite. In north Brazil a deposit of bauxite contains about 20% of P_2O_5, but so intimately mixed therewith as to be economically worthless at present. C. A. Silberrad

Farm manure. Robert M. Salter and C. J. Schollenberger. *Ohio Agr. Expt. Sta., Bull.* **605**, 69 pp.(1939); cf. *C. A.* **32**, 8653[6].—The practical handling of farm manure and its utility in maintaining soil productivity are discussed, with data on compn., recovery of fertility elements in feed, chem. changes in rotting, losses of valuable constituents and means for reducing the same, including addn. of superphosphate and other chemicals. 118 references. C. R. Fellers

Decomposition of the organic compounds in barnyard manure. N. Bengtsson and Chr. Barthel. *Trans. Third Comm. Intern. Soc. Soil Sci.* **A**, 133–6(1939).—To a mixt. of dry sand with about 10% ground mixed cow manure including straw and 0.05% KH_2PO_4 was added 0.1–0.2% KNO_3 or equiv. $(NH_4)_2SO_4$, and to a part of each lot H_2SO_4 to change from pH 8 to 6. Portions of 300 g. were moistened with 15% H_2O contg. soil ext. for inoculation, sealed in jars, incubated at 20–22° and examd. annually for 4 yrs., for total N, NH_3, nitrate, α-humus, cellulose, pentosans, lignin, total org. C, pH and protein N. The analytical data obtained are tabulated but not discussed in detail. After 1 yr., the pH of the mixt. without addn. was 7.5, with H_2SO_4 5.5; about 0.1% α-humus was present in all, and 73–95% of the cellulose, 59–84% of the pentosans, 13–38% of the lignin, 28–55% of the total org. C and 4–16% of the protein originally present had been decompd. Four-yr. samples were at about pH 7 and 5, resp., with little change in humus; 82–100% of the cellulose, 68–92% of the pentosans, 22–61% of the lignin, 44–71% of the total org. C and 15–44% of the protein had been decompd. The decompn. proceeded farther in the alk. mixts. The addns. of N, narrowing C/N from 99 to 46 or 30, had no significant effects upon the course of decompn. C. J. Schollenberger

Comparison of different sulfates used as fertilizer. P. Boischot, G. Drouineau and J. Herviaux. *Compt. rend. acad. agr. France* **25**, 939–44(1939).—The addn. of

S in the form of $(NH_4)_2SO_4$, K_2SO_4 or $CaSO_4$ (superphosphate) gave increased potato yields. The S of the superphosphate was most effective as it was not removed from the soil as rapidly as the S from $(NH_4)_2SO_4$ or K_2SO_4 and consequently remained in contact with the plant roots for a longer time. In calcareous soils, the superiority of K_2SO_4 over KCl was due in large part to the presence of the S. J. R. Adams

Content and effect of boron in some artificial fertilizers, farmyard manure, wood ashes and seaweeds. M. Ödelien. *Meldinger Norges Landbrukshögskole* **19**, 239–70(1939); cf. *C. A.* **33**, 3949[1].—Several pot expts. show a great effect of B deficiency and of exceedingly small quantities of B on plant growth and crops. The increase in the crop of dry matter was up to 76,000 times that of the quantity of B applied. Of the fertilizers commonly used in Norway, it is only farmyard manure which seems to be of importance for the supply of B to the plants. Relatively small amts. of B added to a single fertilizer may, in the course of a series of years, provide as much B as the quantity of farmyard manure commonly applied in Norwegian agriculture. V. Aschehoug

The method of proximate analysis and its application to the study of plant residues, composts and humus formations. Selman A. Waksman. *Trans. Third Comm. Intern. Soc. Soil Sci.* **A**, 101–19(1939).—A review and discussion of the advantages of the analytical methods of W. and Stevens (cf. *C. A.* **24**, 2965) compared with others applicable to soils, marine sediments, composts, humus fertilizers, sewage sludges, garbage, etc. The course of decompn. of org. matter in these materials is outlined and briefly discussed. 101 references. C. J. Schollenberger

Seaweed. E. G. Ing. *Gardeners' Chronicle* [3], **103**, 165–6(1938).—Fresh seaweed collected on the Jersey coast contains 1500 lbs. H_2O, 400 lbs. organic matter, 100 lbs. of ash, 8–14 lbs. N, 15–20 lbs. K_2O, 2–6 lbs. phosphoric acid, 10–12 lbs. of CaO and 30–40 lbs. NaCl per ton. "Colley" (*Laminaria digitata*) in the fresh state contains 1.12% of K_2O or 5.7% when dry. The K_2O content of *Fucus* varies from 0.55 to 0.83 in the fresh weed and from 2.2 to 3.6% in the dried weed. Owing to the rapid loss of soluble salts and gases seaweed should not be allowed to rot alone but should be composted. Colin W. Whittaker

Hypochlorite oxidation of decomposed plant residues. Arthur G. Norman. *Trans. Third Comm. Intern. Soc. Soil Sci.* **A**, 85–93(1939).—Expts. on oxidation of various plant residues with nearly neutral or unadjusted hypochlorite solns. at high diln., e. g., 50 mg. acid lignin with 100 ml. NaOCl soln. contg. 200–250 mg. available Cl for 2 hrs. to 5 days but with other conditions not specified, led to the following conclusions: Aerobic decompn. processes result in the progressive accumulation of lignin and nitrogenous complexes peculiarly susceptible to oxidation by hypochlorite. Lignin does not change in reactivity during natural decompn. processes; hence the NaClO oxidation with conditions carefully controlled for uniformity and with a large initial excess of oxidant is adapted to study of the humus layers on a forest floor, in peat deposits, etc. The method is not adapted to comparisons of widely varied materials, however, and does not furnish abs. results because the reaction is practically only about 1/3 complete. The indications are not a measure of the "degree of humification," but of the accumulation of lignin and resistant nitrogenous residues. Ten references. C. J. Schollenberger

Chemical treatment of winter wheat seed as a measure to increase frost resistance. A. Vetukhova. *Compt. rend. acad. sci. U. R. S. S.* **24**, 605–8(1939)(in English).—In continuation of previous research (cf. *C. A.* **33**, 6386[9]), it was sought to increase the frost resistance of winter wheat by the application of KSCN, KI, KCl, K_2SO_4, NaCl, $CaCl_2$, $BaCl_2$, NaOH, KOH, $Ba(OH)_2$, $Ca(OH)_2$ and some phosphates. The effect of the salts and hydroxides of alkali metals in 0.01 *N* and 0.001 *N* concns. is one of increasing frost resistance of plants under natural conditions of hibernation. The same is true of the action of the trisubstituted K phosphate. The stability of the colloidal system was also strongly affected by the chem. treatment of the seeds. Substances and concns. increasing the hydrophility of the colloids also increase frost resistance. 7 references. A. H. Krappe

Resistance of azaleas to fumigation with methyl bromide. J. Lounsky. *Bull. inst. agron. sta. recherches Gembloux* **8**, 126–31(1939); cf. *C. A.* **33**, 5115[5].—With few exceptions, fumigating azalea plants in vacuum for 2 hrs. with MeBr at the rates of 40 and 80 g./cu. m. had no injurious effect on the plants. The tests were made on 34 varieties. J. R. Adams

Deformed heart of cabbage. III. S. Leefmans. *Mededeel. Tuinbouw-Voorlichtingsdienst* No. **11**, 52 pp. (1939).—Biol. information is given for the midge, *Contarinia nasturtii* Kieffer, which causes deformed heart of cabbage and cauliflower in Holland. The most economical spray is 0.1% nicotine + 1.5% soap or + 0.5% NH_3 and 0.75% oleic acid, both of which give satisfactory control of the emerged adults. Pyridine at 2% concn. is necessary in years of severe injury. Derris alone or with $C_{10}H_8$ is less satisfactory and more costly. Soil fumigation with CS_2 to kill larvae and pupae showed promise. E. J. S.

[Report on] tobacco research. Anon. *New Zealand Dept. Sci. Ind. Research, Ann. Rept.* **13**, 75–80(1939).—In the *soils* of the Tobacco Research Sta. the coarse, medium and fine sands contained 0.03, 0.06 and 0.075 p. p. m. B, resp. Six samples of *tobacco leaf* from the Riwaka district averaged CaO 4.86, MgO 0.81, Fe 0.014, Mn 0.0048, N 2.05 and P_2O_5 0.49% and B 24 p. p. m. on the dry basis. The Mg, Mn, N and B contents of the samples showed considerable variation. *Disinfection of tobacco seed* with either alc., $AgNO_3$ or Uspulun had no significant adverse effect on germination of the seed but usually had a beneficial effect. The *mosaic disease* was accentuated in plants that received extra applications of K fertilizer, whereas high applications of N fertilizer had an ameliorating effect. It appears that, within certain limits, the N:K ratio rather than N alone is the factor operating in overcoming the dwarfing tendency produced by the virus. K. D. Jacob

Control of sweet-potato wilt by chemical treatments. T. F. Manns and J. W. Heuberger. *Del. Agr. Expt. Sta., Bull.* **214**, 30–2(1938); *Ann. Rept.* **1938**; cf. *C. A.* **32**, 6390[3].—The wilt disease caused by *Fusarium batatatis* was fairly well controlled by sprout dipping treatments with various Cu and Hg compds. such as $HgCl_2$ (1 oz. to 16 gal. of water), Bordeaux mixt. (4–4–50), Cuprocide (3–5 lb. to 50 gal. of water), New Improved Semesan Bel (1 lb. to 8 gal.) and Coposil (6 lb. to 50 gal.). The use of nutrients in the dipping soln. may aid by insuring rapid growth of the sprouts immediately after planting. C. R. Fellers

Effect of the injuries caused by Eurygaster integriceps Put. on the baking properties of wheat. A. I. Marushev and K. P. Grivanov. *Socialistic Grain Farming* (U. S. S. R.) **1938**, 187–91(in Russian); *Rev. Applied Entomol.* **27A**, 554–5(1939).—Analysis showed no gluten in wheat flour prepd. from grains of which 25% had been damaged by this pentatomid, and loaves baked from this flour did not rise and were not sufficiently porous. The life history of the pest is given and biol. control methods are suggested. Edwin J. Seiferle

Personal experiences in the control of grape-vine mildew. H. V. Gole. *Agr. Live-Stock India* **9**, 155–6 (1939).—The Imp. Chem. Industries Ltd., Bombay, prepd. 2 Cu fungicides, a CuO paste and a Cu_2O powder (the latter known in trade by the name of Perenox) as substitutes for Bordeaux mixt. These 2 fungicides were given a trial in 1937 and each was sprayed on 80 vines separately. Three sprayings were given and these proved adequate to give effective protection to the crop from the mildew. The results proved very satisfactory, but as the weather conditions at the time of the trials were not very favorable for the infection and growth of the disease, another trial was given during 1938. A plot contg. 260 vines was selected for the expt. A mixt. of Cu_2O was prepd. by mixing 1 lb. of powder to 40 gal. (USA) of water. The vines were pruned on the 1st of April and were given

their 1st spray on the 20th of May. The 2nd spray was given on the 18th of June. A dusting with S was given between the 2 sprays. The results were satisfactory. A 33% mixt. of Perenox showed better results than Bordeaux mixt., but the results require further confirmation. Other advantages in using Perenox in preference to Bordeaux mixt. are: (1) It can be prepd. quickly and without much difficulty. The compn. of Perenox remains const. for a given strength of the mixt. (2) It remains in suspension for a longer time and does not deteriorate by keeping for a day or two. (3) It is not affected by the atm. and therefore does not lose its fungicidal properties. It may keep its effect for more than 20 days with full potency throughout the period. (4) It will not cause any leaf-burn injury, observed occasionally when Bordeaux mixt. is used. The CuO paste had given good results in 1937 but it was not available for trial in 1938. The paste leaves dark spots on bunches and thereby spoils their appearance. It use was therefore considered objectionable. The paste requires to be kept in air-tight containers as otherwise it gets dried and loses its phys. texture. A sudden and severe attack of powdery mildew was also checked quickly by a liquid spray of $KMnO_4$ (8 oz. to 40 gal. of water). This should be followed immediately by dusting with S. Edward A. Ackermann

Use of chloropicrin in nematode control. H. Goffart. *Anz. Schädlingskunde* **15**, 121–5(1939).—Field expts. were carried out against the potato nematode, *Heterodera schachtii*. Two portions of bare land were wet with 10 cc. chloropicrin (I) in 2 l. H_2O/sq. m., and 2 with 20 cc. I in 2 l. H_2O/sq. m.; one of each of these pairs was carefully covered with roofing paper, while the others were left open. Another area was injected with 4 10-cc. portions of I/sq. m. placed in holes 15–20 cm. deep and 50 cm. apart. Two untreated check areas were left. After 4 weeks potatoes were planted in these areas and growth of plants and degree of infestation by nematodes were observed. Results showed that growth differences in covered and open areas were slight, and growth was poor on the untreated areas. The injected area showed the best, almost complete, control of the nematodes. It appeared to be essential for good control that the soil be covered after treatment. There is considerable discussion of mech. handling of I. 33 references. E. J. S.

Biology and control of Rhizoecus kondonis Kuw., a citrus pest. H. Saito. *Agr. and Hort.* **14**, 1761–6 (1939)(in Japanese); *Rev. Applied Entomol.* **27A**, 617 (1939).—This coccid attacks rootlets of citrus in Japan. Biol. data are given. Chloropicrin and Ca cyanamide are effective for control, but injure the trees, while CS_2 is less effective. A H_2O soln. of cyanide (0.7% in winter and 0.3% in summer) gives good control and does not injure the trees. Edwin J. Seiferle

Some mealy bugs of Egypt and experiments on their control by means of chemicals. M. Beshir and M. Hosny. *Ministry Agr. Egypt, Tech. Sci. Service, Bull.* No. 209, 16 pp.(1939).—Good control of the hibiscus mealy bug (*Phenacoccus hirsutus* Green) was obtained by spraying the infested plants with either tar oil (4–5%) or Volck mineral oil (2–3%) emulsions. Because of foliage injury, tar-oil sprays were not satisfactory for citrus trees, vegetable crops and ornamental flowering plants, but they were not injurious when they were applied to deciduous plants in autumn or winter. K. D. Jacob

Brief report of an experiment in combating Helopeltis on cacao by dusting with derris. J. G. Bettem. *Bergcultures* **12**, 1790–6(1938); *Rev. Applied Entomol.* **27A**, 523.—Applications of a dust consisting of 1 part 10% rotenone-contg. derris powder in 13 parts talc produced temporary reduction in no. of nymphs and adults of *H. antonii Sign.* on cacao in Java. Edwin J. Seiferle

Grasshopper control methods developed in both laboratory and field. R. R. Walton and F. E. Whitehead. *Okla. Agr. Expt. Sta., Ann. Rept.* **1936–1938**, 79–82 (1939); cf. *C. A.* **32**, 2276[3].—Two years' field tests show that max. control in Okla. is obtained by liberal use of an inexpensive bait consisting of 50 lb. each of bran and sawdust, 4 lb. of Na arsenite and 10–12 gals. of water. Cottonseed hulls can be advantageously substituted for the sawdust. The addn. of Am acetate or ground lemons did not appreciably increase the attractiveness of the bait. C. R. Fellers

Effectiveness of pyrethrum against the eggs of Chilo simplex Butl. T. Onoe and J. Hukuda. *Oyo Dobuts. Zasshi* **11**, 146–7(1939); *Rev. Applied Entomol.* **27A**, 620 (1939).—Expts. in Japan showed that pyrethrum exts. in 0.5% soap soln. are more effective against week-old eggs of *C. simplex* than against those that are a day old. Since developed embryos were observed in all the eggs killed, it is considered that the pyrethrum affects embryos in a late stage of development. A soln. with a pyrethrin content of about 0.009% killed all the eggs. E. J. S.

Entomological notes from Bahia. IV. G. Bondar. *Rev. Entomol.* **10**, 1–14(1939).—B. discusses the taxonomy and economic importance of several pests of cocoa in Bahia. In combating the hemiptera, *Monalonion* spp., which may cause a crop loss up to 50–60%, a spray of kerosene and soap emulsion or of Bordeaux mixt. is effective. Edwin J. Seiferle

[Report on] fruit research. Anon. *New Zealand Dept. Sci. Ind. Research, Ann. Rept.* **13**, 66–72(1939).—$ZnCl_2$, $HgCl_2$ and $Hg(CN)_2$ solns. gave no *control of apple canker*, caused by *Nectria galligena*. A soil dressing of 0.5 lb. borax per tree gave com. *control of internal cork of apples* for at least 3 seasons. Borax sprays (0.1–0.2%) caused no foliage injury when they were used to control internal cork, provided the spray soln. was thoroughly mixed and lime was used in conjunction with the Pb arsenate sprays. *Premature defoliation of apple trees*, which seems to be caused by Mg deficiency, was overcome by injecting Mg salts into the trees. Low figures for Mg in apple leaves were assocd. with high figures for K. *Control of brown-spotting of apricots* was effected by spraying the trees with 0.1% borax soln. or by applying 0.5 lb. borax as a top-dressing around the tree in the spring. Fruit from B-treated trees contained 34.5–46.5 p. p. m. of B as compared to 5.7 p. p. m. in fruit from control trees. There was definite evidence that *pitting of cherries* is assocd. with low B content in the fruit. K. D. Jacob

Orchard insects of 1938. C. H. Richardson and Harold Gunderson. *Trans. Iowa State Hort. Soc.* **73**, 139–47 (1938); cf. *C. A.* **33**, 4732[1].—Ca arsenate was slightly less effective than Pb arsenate in preventing entries and stings of apples by codling moth. The efficiencies of arsenate sprays were not increased by the use of soybean flour as a sticker and spreader, but the As content of fruit that received such sprays exceeded the legal tolerance and was approx. 3 times that of fruit that received Pb arsenate-lime sprays. The use of soybean flour in arsenical sprays is inadvisable unless the fruit is to be washed for spray-residue removal. K. D. Jacob

The false tiger of pear (Monostira unicostata Mls. Hem. Heter.). J. P. Vidal. *Bull. soc. hist. nat. Afr. nord* **30**, 27–32(1939); *Rev. Applied Entomol.* **27A**, 570.—A spray consisting of 5 lb. of 40% nicotine sulfate, 1 [Brit.] gal. CH_3OH, 10 lb. castile soap and 100 [Brit.] gal. H_2O gave complete mortality of the nymphs of this tingid in Morocco, and did not injure the foliage of pear. The description and bionomic notes of the pest are given. E. J. S.

The peach tree borers of Illinois. S. C. Chandler. *Illinois Natural Hist. Surv. Div. Circ.* **31**, 36 pp.(1939).—The peach borer, *Conopia exitiosa* (Say), was controlled 98% in 13-yr. old trees by application of 2 oz. *p*-$C_6H_4Cl_2$ (I) around the base of the tree, care being taken to allow no direct contact with the tree, and covering the crystals with earth. The most effective times for application coincide with periods when the soil temp. is at least 55°F., the min. for effective volatilization of the compd. Four liquid substitutes, cottonseed-oil emulsion, mineral-oil emulsion and Dendrol, a miscible oil (II), all impregnated with I, and $C_2H_4Cl_2$ emulsion (III) (without I) are as effective under normal treating temps. as I, and appear to be less likely to injure the trees. Dichloroethyl ether was not so satisfactory. In cold soil III is more effective than I. Solns. of I in II and in Niagara Tar Oil gave good control of the lesser peach borer, *Synanthedon pictipes* (G. &

R.), when painted on the injured areas, but the latter is more likely to injure the tree. Adult shot-hole borers, *Scolytus rugulosus* Ratz., were fairly well controlled by the soln. of I in II, but the grubs were not appreciably affected. Treatment with I injures nursery stock. E. J. S.

The tung-oil tree measuring-worm, Buzura suppressaria Guen. (Lepidoptera). Ming-Tsang Cheo, Chi-Ying Liu and Tung-Lwen Ma. *Chedah Agr. Quart.* **1**, 137–205 (1937)(English summary); *Rev. Applied Entomol.* **27A**, 614(1939).—Biol. data are given for this defoliating pest and cultural practices for its control are outlined. Pb arsenate and pyrethrum were effective larvicides, but the latter is too costly to be practical. Edwin J. Seiferle

A new insect pest of chrysanthemum. W. E. H Hodson and S. G. Jary. *Agriculture* (England) **46**, 54–6(1939); *Rev. Applied Entomol.* **27A**, 519.—A nicotine-soap wash gave some control of the leaf-mining larvae of the trypetid, *Paroxyna misella* Lw., a new nursery pest in Britain. The insect also caused terminal galls. Biol. observations were made. Edwin J. Seiferle

Diptera as pests of agricultural plants. I. R. Nozu *J. Plant Protection* **26**, 482–91(1939)(in Japanese); *Rev. Applied Entomol.* **27A**, 556.—Spraying with nicotine sulfate killed the larvae of *Chloropisca notata* Mg. in the leaves of rye. Derris was also effective. Biol. observations are given. Edwin J. Seiferle

Injuriousness of the wheat thrips (Haplothrips tritici Kurd.). K. P. Grivanov. *Socialistic Grain Farming* (U. S. S. R.) **1938**, 179–86(in Russian); *Rev. Applied Entomol.* **27A**, 554(1939).—Analysis showed that heavily infested wheat still contained 28% gluten and so was suitable for baking. Data are given on the degree of infestation of the grain and the resultant effect on grain wt. Edwin J. Seiferle

Construction of nests of Atta cephalotes L. and Atta sexdens L. (Hym. Formicidae). Gerold Stahel and D. C. Geijskes. *Rev. Entomol.* **10**, 27–78(1939)(in German).—These leaf-cutting ants are injurious to cultivated plants in Dutch Guiana. A detailed study was made of their nests as a basis for control. CS_2, poured into the nests through the entrance and the latter then stoppered with earth, gives good control of *A. cephalotes* but is less satisfactory against *A. sexdens*. Edwin J. Seiferle

The occurrence of the fir needle aphid in the municipal forests of Zofingen. Siebenmann. *Schweiz. Z. Forstw.* 90, 190–2(1939); *Rev. Applied Entomol.* **27A**, 517.—*Chermes nordmannianae* Eckstein was well controlled on silver fir when dusted with a com. insecticide during the period (September) when it has no wax coating. Winter spraying with a tar distillate or an oil emulsion was also effective. Forestral practice is outlined. E. J. S.

Pests of cocoa in the territory of New Guinea. J. L. Froggatt. *New Guinea Agr. Gaz.* **4**, 66–8(1938); *Rev. Applied Entomol.* **27A**, 544.—Larvae of the cerambycids, *Dictamnus*, can be destroyed by introducing small quantities of *p*-$C_6H_4Cl_2$ into their mines. A 5% soln. of *p*-$C_6H_4Cl_2$ in kerosene killed the termites, *Calotermes papua* Desn., when poured into their workings. Other pests are enumerated. Edwin J. Seiferle

Great outbreak of the winged locust, Eirenephilus longipennis Shiraki in 1938 in the province of Tokati, and the actual results of its extermination. S. Kuwayama and K. Osima. *Oyo Kontyû* **1**, 251–68(1939); *Rev. Applied Entomol.* **27A**, 618(1939).—Petroleum oil as a spray gave 90% mortality of this and other acridians, but was not so effective as a dild. emulsion. A spray contg. 3 lb. pyrethrum, 2 lb. soap and 48 gal. H_2O gave 36% mortality and paralyzed many more hoppers. Biol. and ecological information are given. Edwin J. Seiferle

Proposed standard method for testing fungicides. R. R. L. Fernbach, Nicholas D. Duffett and Clarence L. Weirich. *J. Bact.* **39**, 8(1940).—The method differs from the Federal Food and Drug Administration phenol coeff. technique in method of prepn. of the inoculum. *Tricophyton roseceum* is grown in Petri dishes on Sabouraud A agar, the whole culture transferred to a flask and shaken with glass beads and saline, filtered through cheesecloth, the spores are washed with saline and made up to contain 10,000 spores per cu. mm. John T. Myers

Biological technique for the evaluation of fungicides. A. E. Muskett. *Agr. Progress* **16**, 212–17(1939).—A lab. method for detg. the efficiencies of fungicides in controlling *Helminthosporium avenae* Eid. in seed oats is described. Select at random a sample of 500 seed oats from an infected bulk sample that has been treated with fungicide and arrange the grains equidistantly in 9-cm. Petri dishes (15 grains per dish) the bottoms of which are lined with 2 moist filter papers per dish. Pack the closed dishes in an open container, cover with a damp cloth and place the container in an incubator at 22°. After 4 days take the dishes out of the container, remove the lids and expose the seeds to light from a Hanovia quartz Hg-vapor lamp, operating at a distance of approx. 30 cm., to stimulate sporulation of the fungus. Return the dishes to the incubator as before and on the 9th day examine the seeds for the presence of *Helminthosporium* in an actively sporing state. In detg. the results only those seeds which show the presence of spores produced *in situ* upon conidiophores are counted as infected or improperly disinfected. The results obtained by this test agree very closely with those from pot and field tests. If in a control sample showing approx. 50% of infected grains, the test reveals the presence of 5% or more infected grains, the fungicide is likely to be of little value and is rejected for further testing. Should the percentage fall between 0 and 5 a re-test is made and the sample is rejected after this 2nd test if the infection is greater than 1%. When the infection falls between 0 and 1% the sample is subjected to pot and field tests. K. D. Jacob

Wood ash as a repellent against insect pests. T. Moriyama. *Formosan Agr. Rev.* **35**, 500–4(1939)(in Japanese); *Rev. Applied Entomol.* **27A**, 618(1939).—In lab. expts. *Ceratia* (*Rhaphidopalpa*) *similis*, a pest of cucurbits, did not feed on cucumber leaves dusted with ash, but accepted leaves wet with water filtered from the ash which had been steeped in it. M. concludes that the repellent action of the dry ash is due, therefore, to phys. causes. Edwin J. Seiferle

Distribution of nicotine between water and petroleum oils. L. B. Norton. *Ind. Eng. Chem.* **32**, 241–4(1940).—The distribution ratio of nicotine between H_2O and petroleum oils is 1.11:1 at concns. below 1%; it increases with increase in concn. to > 6:1 at 50–70% nicotine and then decreases at higher concns. An excess of acid drives the nicotine completely into the H_2O phase while smaller amts. hold equiv. amts. of nicotine in the H_2O. Alkalies in concns. above 0.1 *N* drive the nicotine into the oil phase and soln. in the oil is complete with 5 *N* NaOH. Only the nicotine in the free state is shared with the oil. Nicotine in spray mixts. is distributed in approx. equal concns. in the oil and H_2O regardless of the concn. of the nicotine and of the presence of fungicides or emulsifiers. Transfer of some of the nicotine from H_2O to oil occurs as the spray dries on foliage. John O. Hardesty

α-Naphthylacetylamino acids. Otto Isler (to Hoffmann-La Roche Inc.). U. S. 2,179,979, Nov. 14. α-Naphthylacetylglycine, m. 153–4°, is formed by treating α-naphthylacetyl chloride with glycocoll. It forms water-sol. alkali salts. Production of α-naphthylacetyl-*l*-leucine, m. 146–7°, and of α-naphthylacetylsarcosine, m. 147–8°, also is described. These compds. may be used for *promoting the growth of plants* and as dissolving agents. 4

Insecticide. Alexander Wacker, Ges. für elektrochem. Ind. G. m. b. H. Fr. 840,969, May 8, 1939. An insecticide contg. finely divided Cu oxychloride 10–20 parts, S 10–30 parts and other substances capable of increasing the suspension capacity of the insecticide, such as bentonite, 50–60 parts. 5

Insecticide and fungicide. Russell W. Millar and Russell L. Maycock (to Shell Development Co.). Can. 386,197, Jan. 9, 1940. A soln. contg. NH_3 and H_2S is prepd. in a molar ratio between 2.6:1 and 2.7:1, and then satd. with S.

16—THE FERMENTATION INDUSTRIES

C. N. FREY

Hydrogen-ion control in brewing. Benno Lowy. *Pacific Chem. Met. Inds.* **4**, No. 1, 7–9(1940).—A review. E. H.

Some researches on Saccharomyces cerevisiae. G. Luchetti and E. Bartolini. *Ann. facoltà agrar. univ. Pisa* [N.S. 3rd.] **2**, 608–18(1939).—The optimum conditions 7
for fermentation of glucose are: acidity (calcd. as H_2SO_4) 0.5%, peptone 0.35%, concn. of the sugar 2–3.5%, P_2O_5 0.03%, temp. about 32°. G. A. Bravo

Bulgaria's typical milk product—joghurt. Janks Antonoff. *Deut. Molkerei-Ztg.* **60**, 1035–6(1939).—Directions are given for the prepn. of joghurt. The pure cultures and the properties of joghurt are discussed. A. L.

Calculation of the initial density of must which has 8
undergone partial alcoholic fermentation to produce a natural sweet wine. Henri Laganne. *Ann. fals.* **32**, 330–4(1939).—Mathematical. A. Papineau-Couture

Composition of the outer coats of barley. Etienne Ivanyi. *Brasseur franç.* **3**, 470–1(1939).—The 3 outer coats of barley can be detd. by treating the grain for 30 min. at 50° with 45% (exactly) H_2SO_4, removing the softened outer coats by means of a hand-operated mech. stirrer, and sepg. them by levigation. The percent- 9
age of the outer coats decreases as the size of the grain increases. In order to evaluate correctly the influence of the outer coats, they should be calcd. to a basis of the same external surface of the grain. A. Papineau-Couture

Distinction between the nitrogenous constituents of barley. Urion and Raux. *Brasseur franç.* **3**, 393–403 (1939).—A crit. study was made of some aspects of **Bishop's method (*C. A.* 22, 3729). The fineness of the** flour considerably influences the degree of extn. of the various nitrogenous fractions; when the degree of extn. reaches a max., microscopic examn. shows that grinding has destroyed all cellular organization, but has left the starch grains intact. For the barley variety that was studied, the limiting values obtained confirmed the principle of the regularity of the nitrogenous compn. and the exptl. results of Bishop. Tests using tannin are not satisfactory owing to the nonspecificity of the reagent. In the analysis of the saline dispersion, it is advisable to use only reagents and operations which, in buffered medium, give reproducible pptns.; this led to elimination of a no. of reagents, and to the retaining of heat, $MgSO_4$ and uranyl acetate. A. Papineau-Couture

Relation between the chemical composition of barley and that of the malt obtained from it. L. R. Bishop. *Brasseur franç.* **3**, 374–7(1939).—Certain regularities have been noted in the chem. compn. of barley. The percentage of each type of protein is related to the total N content, and that of each type of carbohydrates depends on the total carbohydrate content. The proportions of each of the constituents taken individually are varietal characteristics. These regularities persist in the malt and in the wort, so that the compn. of the malt and the wort can be predicted from that of the barley, which permits an easy control of malting conditions and of barley selection. A. Papineau-Couture

Nitrogenous composition of barley and malt and its relation to disintegration. Hermann Fink. *Brasseur franç.* **3**, 377–81(1939).—**The nitrogenous compn. of barley depends on the percentage total N and the variety.**

Increase in total N is accompanied by a decrease in salt-sol. and increase in alc.-sol. N (expressed as percentage of total N); the glutelin content remains substantially const. for a given variety and shows little if any variation between varieties. Lab.-scale malting tests showed that a barley with high salt-sol. N content, when malted by a definite method, always gives a malt with high salt-sol. N content; and a malt with high salt-sol. N content gives a wort high in N (calcd. on the N content of the malt). It follows that the solubilization value of malt depends directly on the nitrogenous compn. of the barley, and hence on the total N content and variety. A. P.-C. 1 2

Mutual relation of albumin and starch contents in malting barleys. C. Krügel, C. Dreyspring and F. Heinrich. *Superphosphate* **12**, 177–83(1939); cf. *C. A.* **25**, 5493; **27**, 1439.—The proportion of albumin and starch changes not only with the different varieties in the same exptl. yr., but also with the same variety in different yrs.; a decrease in the albumin content is invariably accompanied by an increase in the starch content and vice versa. Both albumin and starch are in mutual relationship in the barley grain, but the proportion is not rigid. These results are not contradictory to those obtained by Wimmer and Lüdecke (*Landw. Vers.-Sta.* **125**, 129–60(1936)). K. D. Jacob 3

Yield differences and viscosity as criteria of malt disintegration. Paul Kolbach. *Brasseur franç.* **3**, 355–8 (1939).—A general discussion. A. Papineau-Couture 4

Can the malting process be recognized by analysis of the malt? Eugène Ketelbant. *Brasseur franç.* **3**, 359–63(1939).—From a general discussion of the problem, it is concluded that there are too many factors involved to give certainty on the basis of the analytical results. A. Papineau-Couture

Relations between malting conditions and malt quality. B. D. Hartong. *Brasseur franç.* **3**, 341–4(1939).—A general discussion. A. Papineau-Couture 5

Malt analysis and the information it can give regarding the quality of malt. Curt Enders. *Brasseur franç.* **3**, 352–5(1939); *Brewers Digest* **15**, No. 2, 21–4T(1940).—A general discussion. A. Papineau-Couture

Malt analysis. A. Popp. *Brasseur franç.* **3**, 467–8 (1939).—A brief discussion of the ordinary so-called "com." analysis of malt, outlining the significance and interpretation of the chief detns. A. Papineau-Couture 6

Relation between the qualities of malt and of beer. F. Tombeur and J. de Clerk. *Brasseur franç.* **3**, 444–8 (1939).—From a discussion of published work and from tests carried out on 22 brews of Pilsen beer, it is concluded that, as a rule, well-disintegrated malts obtained from the best barleys give the best beers, but there are numerous exceptions. A. Papineau-Couture 7

Correction of water for the brewery. Robert van Dacle. *Fermentatio* **1939**, 337–51.—An address briefly reviewing the properties of the constituents of natural water from the standpoint of the brewing industry, the chief processes of water treatment and their relative suitability for brewery waters. A. Papineau-Couture

Influence of malt quality on the technology of beer making. H. Lüers. *Brasseur franç.* **3**, 423–7(1939).—A discussion and review with 71 references. A. P.-C. 8

Air and beer. R. de Smedt. *Fermentatio* **1939**, 355–61, 371–86.—A review of the action of air on the following factors: turbidity due to yeasts and to oxidation, foam, bitterness, color, "sunlight" taste, "pasteurized" taste. A. Papineau-Couture

The factors which govern the characteristics of beers. J. Raux. *Brasseur franç.* **3**, 320–4(1939).—An address. A. Papineau-Couture 9

The "volutin" of yeast. P. Biebuyck. *Fermentatio* **1940**, 3–13.—"Volutin" consists of granular formations in the yeast, which serve as reserve material and which can be colored by various dyes, particularly methylene blue. There is no direct relationship between the volutin content of yeast, on the one hand, and its fermenting power or protein content, on the other. Volutin disappears during the storing of yeast; most rapidly if it is kept under water, less rapidly if kept dry, and least rapidly when kept under a nutritive medium (suitably beer). Volutin increases considerably during fermentation, provided the fermenting medium contains the necessary nutritive elements, especially P; the denser the wort, the higher the volutin content. Dil. H_2SO_4 and alk. earth bicarbonates exert an adverse influence on the formation of volutin. A. Papineau-Couture

Chemistry and bromatology of mangarito and mandioquinha (Fonseca Monteiro, Abrantes Bueno) **11D.**

Transformation of lactose of whey into ethyl alcohol. Willm Kauffmann. Fr. 840,863, May 5, 1939. A pure culture of a lactic enzyme is added to whey, and in 3 days 70% of the lactose is transformed into ethanol. The pure culture is taken from substances contg. lactic enzymes such as cheese.

Denatured alcohol. Louis J. Figg, Jr. (to Eastman Kodak Co.). U. S. 2,179,997, Nov. 14. Ethylenediamine about 0.5–5% is used as a denaturant. U. S. 2,179,998 relates to the use of quinoline and U. S. 2,179,999 to the use of tetrahydrofurfuryl alc. for denaturing alc. Cf. *C. A.* **33**, 7956[2]. U. S. 2,180,000 (Louis J. Figg, Jr., and James W. Rhea, joint inventors; to same assignee) relates to denaturing alc. with use of acetal, dimethylacetal, etc. Cf. *C. A.* **34**, 1126[5].

Artificial maturing of alcoholic liquors. Lucius F. Little. U. S. 2,180,685, Nov. 21. A liquor such as new whiskey, in contact with charred wood, is subjected to the action of infrared rays (suitably for 48–170 hrs. and at a temp. of about 45–65°). App. is described.

Purifying neutral oils derived from distillation of hard wood. Louis J. Figg, Jr. (to Eastman Kodak Co.). U. S. 2,180,001, Nov. 14. A purified product suitable for use in *denaturing alc.* is obtained from "neutral" oils by extg. impurities from them with ethylenediamine, distg. the oil through steel wool and washing out the residual ethylene diamine, as by use of a 1% soln. of H_2SO_4 and of water.

Liquid-treating apparatus suitable for cooling wort and treating it with conditioned air, etc. Harry G. Mojonnier (to Mojonnier Bros. Co.). U. S. 2,179,949, Nov. 14. Various structural and operative details.

Beer substitute. Georg Roeder. Fr. 841,151, May 10, 1939. A feebly alc. beverage, rich in nutritive elements, is obtained by mixing whey with malt and subjecting the mash to the usual treatments of brewing. Prior to the operation, the whey is freed from albumin by heating and adjusted to a degree of acidity favorable to diastatic action.

17—PHARMACEUTICALS, COSMETICS AND PERFUMES

W. O. EMERY

Odoriferous principle of green tea. XI. Primary alcohols from the oil of black tea. Sankiti Takei, Yzaïro Sakato and Minoru Ono. *Bull. Inst. Phys. Chem. Research* (Tokyo) **17**, 871–9(1938); cf. *C. A.* **32**, 7663[4].—

The oil of black tea contains 10% of alcs., sepd. by fractionation, or conversion into urethans or esters, into BuOH and *iso*-BuOH, *iso*-AmOH, 3-methylbutanol, hexyl alc., 2-hexen-1-ol, octyl alc., benzyl alc., phenethyl alc. and geraniol. B. C. P. A.

Influence of the pH on the stability of solutions of calcium gluconate used in therapy. Emilio Durio. *Ann. chim. applicata* **29**, 463–6(1939).—The stability over a period of 2 yrs. of Ca gluconate in solns. of pH 6.8–7.8 was investigated, a total of 1000 vials being held for examn. Of the samples with pH 7.6 and 7.8, only 0.8 and 0.1% of the vials, resp., showed any pptn. of Ca gluconate. The pH was adjusted by addns. of pure NaOH. A. W. Contieri

An x-ray study of acetylsalicylic acid when incorporated in certain sugars. Ronald L. McFarlan and J. Wallace Reddie. *J. Applied Phys.* **11**, 80–2(1940); cf. U. S. pat. 2,086,386 (*C. A.* **31**, 5949[4]); *C. A.* **32**, 7665[3].— Aspirin (I) was mixed with a sucrose and glucose sirup at 121° and held at this temp. until all visible traces of I disappeared. Debye-Scherrer powder patterns were made of all samples, which were also analyzed for recoverable I by the official A. O. A. C. method. Below a concn. of 0.7% of I the x-ray method cannot detect the presence of cryst. I. Neither does it show whether or not small fractions of I at any of the concns. studied are in any other than the cryst. state. In the samples where I was added at 121° there is no x-ray evidence of cryst. I in excess of 0.7%. The change in the diffuse pattern of the sugar bases on addn. of I also indicates a change from the cryst. to the amorphous state for at least some of the I incorporated at 121°. S. L. Gerhard

Some synthetic pyridine derivatives of therapeutic value, and the preparation of an iodized derivative. Gualtiero Seppi. *Ann. chim. farm.* (Suppl. to *Farm. ital.*) Dec., 1939, 7–14.—Diiodoisopropanol, $(CH_2I)_2CHOH$, heated with pyridine at 120° gave the pyridinium deriv. $[C_5H_5N(I)CH_2]_2CHOH$, needle crystals from alc. m. 216–217°, very sol. in water, insol. in Et_2O, Me_2CO and $CHCl_3$. Other pyridine derivs. of possible pharmaceutical interest are discussed. L. E. Gilson

Arsenic derivatives of thymol and carvacrol and the antihelmintic action of arsenic derivatives of thymol. Mario Filomeni. *Ann. chim. farm.* (Suppl. to *Farm. ital.*) Dec., 1939, 21–31.—Substitution of Cl, Br or I in the *p*-position with respect to the OH slightly increased the vermicidal power of thymol. Substitution of the arsonic acid group, $—AsO_3H_2$, in the same position completely abolished the vermidical activity, and the subsequent further substitution of Br or I in the position between the OH and Me groups did not restore any of the activity. The prepn. of the above bromothymolarsonic acid and also 5-carvacrolarsonic acid and the reduction of the latter to 5-carvacrolarsenoxide are described. L. E. Gilson

Cosmetics for the eyes. H. Janistyn. *Seifensieder-Ztg.* **66**, 678–9, 728–9, 783–4, 823, 853(1939); **67**, 5, 35 (1940).—Recipes are given for prepns. for use around the eye, on lids, brows, pupils, lashes, and eyebrow pencils and lotions. A. Guillaudeu

New violet perfumes. H. Janistyn. *Seifensieder-Ztg.* **67**, 16, 25–6(1940).—Synthetic violet perfumes based on the ionones were improved by adding violet-leaf oil. Nonadien-2,6-al-1 has been recognized in this oil. Leaf alcohol (hexen-3-ol-1) is the carrier of the "green odor" of grasses, leaves, etc. The trans form carries the odor. The cis form does not have this odor. Leaf aldehyde obtainable by oxidation of the alc. with chromic acid, has been recognized in the following green plants: tea, ivy, "Fallnetz," clover, oak, beech, wheat, robinia, mulberry, black radish, violet leaves, cucumbers. Ethereal oil of cucumber consists largely of nonadienol with some nonadienal. Esters of hexenol occur in peppermint oil. Nonadienol and nonadienal are now produced synthetically in Germany. The alc. in amts. of 0.05–5.00% is a valuable addn. to many perfumes. The aldehyde has a very strong odor resembling fresh cucumbers. It may be used in very small proportions. A. Guillaudeu

Alginic acid and its use in pharmacy. A. P. Tatarov. *Farmatsiya* **1938**, No. 4, 11–13; *Khim. Referat. Zhur.* **2**, No. 4, 122(1939).—Alginic acid was obtained from *Laminaria saccharina* (33% of dry wt.). The plant was treated with water, 0.5% HCl soln., 0.5% Na_2CO_3 soln. at 70° and again with HCl. The pure alginic acid (which was in the form of a gelatinous mass) was washed and dried. W. R. Henn

Chemical composition of essential oil of the hybrid of peppermint No. 272. N. I. Libizov. *Farmatsiya* **1938**, No. 6, 28–31; *Khim. Referat. Zhur.* **2**, No. 4, 122(1939); cf. *C. A.* **34**, 1129[6].—The morphological hybrid differs little from the ordinary peppermint. It is little affected by rust (Uredinales); the yield of essential oil is 22.1 kg. per hectare. The essential oil contains menthol 58.83, menthone 6.17, menthyl propionate 7.07, dihydrocarvone 8, *l*-limonene 3 and α-pinene 0.4%. W. R. Henn

The new pharmaceutical agents of 1938. Kurt Handke. *Chem. Ztg.* **63**, 729–32, 740–1(1939); cf. *C. A.* **33**, 9543[3]. E. H.

Cosmetics—a fertile field for chemical research. Florence E. Wall. *J. Chem. Education* **17**, 77 81(1940). E. H.

Fermentation experiments in various tobaccos. I. Mihailovici and I. Trafiuc. *Bul. cultivarii fermentarii Tutunului* **28**, 298 326(in French, 327 9)(1939).—The optimum fermentation conditions (size of fermentation lots, initial humidity) of 4 Rumanian tobacco varieties and various grades were detd. in a series of parallel expts. A. H. Krappe

Extract of the spiny fern. J. Maizite. *Acta Univ. Latviensis, Kim. Fakultat. Ser.* **4**, No. 14(in Lettish, 503–26; in German, 527–8)(1939); cf. *C. A.* **32**, 7213[3].—The rhizomes of 45 samples of *Aspidium dilatatum* collected from different regions of Latvia, contained an av. of 10.15% ext., the av. content of crude filicinic acid in the ext. was 35.12%; the biol. evaluation (quantity to kill small fish in 30 min.) indicates 0.0186 g. In garden plots the ext. reached 12.9% in June, 14% in July and fluctuated from 10.7 to 8.9% during the remaining months, reaching a min. in Oct. Because the rhizomes in southern Germany contained small quantities of filicinic acid, it is apparent that the *Aspidium dilatatum* grown in northern regions is more active than plants grown further to the south. The quantity of ext. produced by *Aspidium dilatatum* fluctuated more than the quantity produced by *Aspidium euspinulosum*. The crude filicinic acid contained quantities of aspidin, albaspidin and aspidinin, traces of flavaspidic acid, and traces of a white substance, "nephrodin," m. at 188–9° and turning red. F. M.

Investigations of medicinal plants. Ilse Esdorn. *Ber. deut. botan. Ges.* **57**, 166–75(1939).—A review of recent German work. Ten references. Lawrence P. Miller

The use of hemolytic complement as a means of measuring the toxicity of antiseptics. Henry Welch, C. M. Brewer and A. C. Hunter. *J. Bact.* **39**, 7–8(1940).—Complement acts as a biocatalyst or activator. By adding appropriate dilns. of germicides to a mixt. of whole blood and artificially opsonized staphylococci, "toxic end points" were obtained at dilns. completely inhibiting phagocytosis. Hemolytic complement resisted greater concns. of germicides than did phagocytic complement; hence the 2 were evidently different. John T. Myers

Evaluation of a number of medicinal dyes by the tissue culture technique. I. L. Schechmeister and A. J. Salle. *J. Bact.* **39**, 8–9(1940).—The medicinal dyes including crystal violet, methyl violet, methyl violet B, methyl violet 6B, brilliant green, methylene blue, proflavine, acriflavine, parafuchsin and neutral fuchsin had pronounced bacteriostatic but poor germicidal power. They were more toxic to embryonic tissue than were the better nondye germicides. John T. Myers

Erythrina alkaloids. V. Comparative curare-like potencies of species of the genus Erythrina. Karl Folkers and Klaus Unna. *J. Am. Pharm. Assoc.* **28**, 1019–28 (1939); cf. *C. A.* **33**, 5404[6].—Data are presented which show the presence of alkaloids with a curare-like action in 28 addnl. species of *Erythrina*. Altogether, 50 species were tested out of the 105 species known to date. The

pharmacol. activity is expressed by "paralysis potency values." No species has been found so far which is devoid of alkaloids of paralyzing activity, although there is a wide variation in the potencies of the seeds of the different species. There is, however, a considerable uniformity of the paralysis potency values of seeds of the closely related species. This uniformity often extends even to certain taxonomical divisions of the genus. The paralysis potency values for seeds of *Erythrina* parallel closely the inherent botanical characters of the plants, and it is possible in some cases when proper herbarium material is absent to distinguish between certain seeds on the basis of this assay. Species of the genera *Rhynchosia*, *Canavalia*, *Clitoria* and *Mucuna* were tested similarly for paralysis potency. All were found to be devoid of alkaloids with the exception of the seeds of *R. pyramidalis* and *Clitoria arborescens*. These were found to possess some curare-like activity which, compared to that of *Erythrina* seeds, was extremely weak and probably represented only traces of active alkaloids. The curare-like action of the exts. of all species of *Erythrina* tested in frogs was of short duration when compared to the duration of paralysis of exts. of curare or curare plants.

A. Papineau-Couture

Chemical investigation of some Florida volatile oils. P. A. Foote and A. W. Matthews. *J. Am. Pharm. Assoc.* 28, 1030–2(1939).—Greenish yellow, mint-flavored oil of *Pycnothymus rigidus* Bart. fam. Lamiaceae had the following characteristics: d_{15}^{20} 0.9323, α_D −4.14°, n_D^{20} 1.4681, acid value 1.75, ester value 135.51, ester value after acetylation 272.17, boiling range 160–220° (greater portion distg. 214–15°). The oil seems to contain pulegone and about 47% of thujyl alc. (nearly all in the free state). Tests for N, S, phenols and aldehydes were neg. Oil of *Solidago rigida* Linné, fam. Compositae had the following characteristics: d_{15}^{20} 0.8500, α_D 38.15°, n_D^{20} 1.4798, acid value 0.39, ester value 8.68, ester value after acetylation 160.15. The main bulk of the oil distd. over at 165°. Tests for N, S, phenols and ketones were neg. The oil probably contains some borneol and also some other alc. or alcs. Presence of α-pinene in the terpene fraction was indicated but not definitely established. Oil of *Erigeron canadensis* Linné, fam. Compositae (showing distinct evidence of resinification) had the following characteristics: d_{15}^{20} 0.8642, α_D 71.70°, n_D^{20} 1.4809, acid value 1.94, ester value 17.12, ester value after acetylation (Boulez's method, *C. A.* 1, 1412) 7505. Less than 20% distd. over at about 145°, about 60% passed over in the region of 170°, leaving a dark brown residue of higher boiling material. Tests for N, S and phenols were neg. A pos. aldehyde reaction was obtained, but the amt. present seems to be very small. The ester value after acetylation by Boulez's method corresponds to 16.82% terpineol. The fraction b. 170.5° probably contains α-limonene. Oil of *Heterotheca subaxilliaris* Lam., fam. Carduaceae had the following characteristics: d_{15}^{20} 0.8877, n_D^{20} 1.4931, acid value 0.48, ester value 26.13, ester value after acetylation 160.91, boiling point (micro method) about 200°. Tests for N and S were neg. The ester values correspond to 9.15% combined and 42.28% free $C_{10}H_{18}O$.

A. Papineau-Couture

Chemotherapeutic studies in the azobenzenesulfonchloroamide series. II. *m*- and *p*-Derivatives. Seymour Stern and Abraham Taub. *J. Am. Pharm. Assoc.* 28, 1032–6(1939).—*Azobenzene-m-sulfonamide*, *m*-$C_6H_5N{:}NC_6H_4SO_2NH_2$, a new intermediate, was synthesized by heating a mixt. of 11 g. *m*-aminobenzenesulfonamide in 46 cc. glacial AcOH and 6.8 g. nitrosobenzene in 40 cc. glacial AcOH at 80–90° for 2 hrs., cooling, pouring on 1 kg. of chipped ice, washing the ppt. with water, refluxing the ppt. 1 hr. in 640 cc. 0.1 *N* NaOH in presence of activated charcoal, filtering, acidifying the hot filtrate with 0.5 *N* HCl, washing the ppt. till free from chlorides, drying (yield 12 g.), recrystg. from 110 cc. of hot 80% MeOH and air-drying, giving a yield of 8.1 g. of black crystals, m. 168–9°, sol. in EtOH, MeOH, Me_2CO, C_5H_5N, hot alkali; insol. in H_2O, C_6H_6, Et_2O, EtOAc or HCl. *Na azobenzene-m-sulfonchloroamide* (I), $C_6H_5N{:}NC_6H_4SO_2N$-$NaCl.2H_2O$, was prepd. by adding 82.8 cc. NaOCl (contg. 0.2899 g. NaOCl per cc. and 2% NaOH) with const. stirring to a mixt. of 5.2 g. azobenzene-*m*-sulfonamide and 50 cc. H_2O over a period of 45 min., heating to 75–80°, cooling rapidly with continuous stirring for 1 hr., washing the ppt. with water, drying (yield 5.3 g.), and purifying by dissolving in 240 cc. of water at 90° contg. 3.24 g. NaOH, 4.3 g. NaCl and 24 cc. NaOCl soln., filtering, cooling, washing the ppt. with water and drying, giving a yellowish orange, amorphous powder, insol. in C_6H_6, CCl_4 and anhyd. Et_2O, sol. in hot H_2O, hot abs. alc., C_5H_5N and Me_2CO. *Azobenzene-p-sulfonyl chloride* was prepd and converted into the corresponding sulfonamide (m. 228–9°) by the method of Gray, *et al.* (*C. A.* 31, 6347[5]), and transformed to *Na azobenzene-p-sulfonchloroamide* (II) by the method of Chrzaszczweska and Dobrowolski (*C. A.* 32, 1674[8]). An attempt to produce *K azobenzene-3,3′-disulfonate* by the method of reduction of Mahrenholtz and Gilbert (*Ann.* 202, 331–40(1880)) yielded K azoxybenzene-3,3′-disulfonate. To prep. the corresponding azobenzene deriv. and avoid the azoxy stage, it is necessary to carry the reduction far enough to produce a colorless reaction mixt. and convert the probable hydrazo compd. so produced to the azo stage by spontaneous air oxidation, which method (technique described in detail) has the advantage of being rapid. *Disodium azobenzene-3,3′-di(sulfonchloroamide)* (III) was prepd. by adding to a well-stirred mixt. of 6.8 g. of azobenzene-3,3′-disulfonamide and 50 cc. of water, 100.5 cc. NaOCl soln. (contg. 0.04443 g. NaOCl per cc. and 5% free NaOH) over a period of 45 min., stirring for 1 hr., washing the insol. material with water, drying (yield 9.1 g.) and purifying by dissolving in a hot soln. contg. 4.8 g. NaOH, 4.8 g. NaCl, 310 cc. H_2O and 50 cc. of NaOCl soln., filtering, adding 150 cc. satd. NaCl soln., cooling, washing the sepd. amorphous material with H_2O, and drying; this yields a product insol. in abs. alc., CCl_4, C_6H_6, dry Et_2O and Me_2CO, sol. in hot water, slightly sol. in hot C_5H_5N. *Disodium azobenzene-4,4′-di(sulfonchloroamide)* (IV) was prepared by adding to 6.8 g. of azobenzene-4,4′-disulfonamide in 50 cc. of water 82.8 cc. NaOCl soln. (contg. 0.05398 g. NaOCl per cc. and 4% free NaOH) with stirring over a period of 45 min., heating to 65°, filtering out the impurities, chilling, stirring 1 hr., satg. with 53.8 g. NaCl, filtering and washing with water, and drying (yield 9.0 g. of orange-red material). It was purified by dissolving in 102 cc. of water at 80° contg. 3.6 g. NaOH and 48 cc. of the NaOCl soln., filtering, adding 450 cc. satd. NaCl soln., heating to 80°, adding 30 g. NaCl, chilling to 25°, washing the ppt. with water, and air-drying, yielding an orange powder, insol. in CCl_4, C_6H_6, Et_2O and Me_2CO, slightly sol. in hot abs. alc. or C_5H_5N, and very sol. in H_2O. Preliminary bacteriol. tests carried out at room temp. against *Staphylococcus aureus* for 5 min. and 2 hr., resp., indicated the following order of activity: chloramine-T 1.0, I 0.15, 10; II 10.0, 100; III 0.1, 10; IV 0.1, 10. Results by the agar cup-plate method indicated that I and II are slightly less penetrating than chloramine-T and II and IV are equal to chloramine-T. A. P.-C.

Salts of isopropanolamine. I. Triisopropanolamine. Geo. W. Fiero. *J. Am. Pharm. Assoc.* 28, 1036–8 (1939).—A study of the salts of triisopropanolamine indicated that their properties made them similar and slightly superior to triethanolamine as emulsifying agents for liquids and creams. Creams prepd. with these salts did not discolor with age to the extent found with triethanolamine creams. **II. Mixed isopropanolamines.** *Ibid.* 1038–40.—A mixt. of 43% di-, 43% tri- and 14% mono-isopropanolamines possessed greater emulsifying power either for pharmaceutical emulsions or cosmetics than triisopropanolamine or triethanolamine. Unlike the latter, it appears that the myristates of isopropanolamines are superior to the laurates as emulsifying agents and possess lower surface tension. Salts of mixed isopropanolamines were softer than either those of triisopropanolamine or triethanolamine and were lighter colored than the latter. Creams contg. mixed isopropanolamines did not become colored on aging to the extent found in triethanolamine creams. A. Papineau-Couture

Water-in-oil emulsifying agents. I. Some constituents of lanolin and similar compounds. J. L. Powers, H. B. Leask and R. S. Warner. *J. Am. Pharm. Assoc.* **29**, 14–17(1940).—The unsaponifiable fraction of lanolin was sepd. into 4 fractions: (1) mixed aliphatic alcs., (2) isocholesterol, (3) cholesterol, (4) an amorphous gummy residue. The relative efficiencies of certain components of lanolin and some analogous compds. as water-in-oil emulsifying agents with petrolatum were detd. The emulsifying efficiency of cholesterol is much less than that of mixts. of cholesterol and cholesterol esters when used with petrolatum for emulsifying water. No one combination of petrolatum and water-in-oil emulsifying agent as a suitable ointment base can be recommended until after further study. A. Papineau-Couture

Hydrogenated oil as an ointment base. II. Geo. W. Fiero. *J. Am. Pharm. Assoc.* **29**, 18–23(1940); cf. *C. A.* **25**, 5737; **34**, 221[6].—Stability to rancidity, consistency and water retention of com. hydrogenated vegetable oils were studied to det. their suitability for ointments; none of the hydrogenated vegetable oils developed more than a trace of rancidity when kept at body temp. in the dark in unstoppered glass tubes, but lard and partially hydrogenated lard became distinctly rancid under the same conditions. In sunlight all the partially hydrogenated oils (I value over 50) developed rancidity to some degree, but less rapidly than lard; hard hydrogenated oils (I value less than 10) did not develop rancidity as rapidly as partially hydrogenated oils. Hydrogenated oils of different manufacturers did not deteriorate exactly in proportion with the I value, but hydrogenated cottonseed oils of various I values prepd. from the same batch of oil deteriorated in relationship to the I value. Of all the com. partially hydrogenated oils, sesame oil was superior from the stand point of rancidity; samples of the same batch of oil hydrogenated to various degrees indicated that it was much more stable than hydrogenated cottonseed oil of the same I value. Two pieces of *app. for dctg. the relative consistency of fats* are described. In the main, the consistency varied with the softening point. The softening point of the same kind of oil from different manufacturers did not vary with the I values, probably owing to the differences in hydrogenating temps., differences in original oils, etc. The data on water retention showed lack of uniformity with samples of different manufacturers; none retained as much water as hard hydrogenated castor oil with the exception of coconut oil contg. lecithin, which retained about 5 times as much as other coconut oils without lecithin. With the exception of partially hydrogenated lard, none of the partially hydrogenated oils retained as much water as partially hydrogenated castor oil. A. Papineau-Couture

Liquor antisepticus N. F. VI. C. O. Beebe, L. W. Busse and A. H. Uhl. *J. Am. Pharm. Assoc.* **29**, 24–6 (1940).—N. F. antisepticus solution (I), before purified talc is used to clarify the product, is a cloudy, milky appearing soln.; the deletion of any one ingredient has little beneficial effect. Boric acid exhibits no effect on the antiseptic value (PhOH coeff.) of I. A higher PhOH coeff. will result upon the reduction of the amts. of volatile oils used in the prepn. of I. If a soln. is to be prepd. which will remain clear at ordinary temps. without clarification, only certain amts. of the ingredients in I can be used. When decreased amts. of the ingredients in I are used, provided the chlorothymol is not less than 0.5 g. per l., the antiseptic value is equal to that of the present official soln. The following formula is offered for criticism: H_3BO_3 25 g., chlorothymol 0.7 g., menthol 0.15 g., methyl salicylate 0.15 g., eucalyptol 0.15 g., oil of thyme 0.05 cc., alc. 300 cc., distd. water to 1000 cc. A. P.-C.

Assay of sarsaparilla preparations. Preliminary report. B. Fantus and H. A. Dyniewicz. *J. Am. Pharm. Assoc.* **29**, 26–8(1940).—If saponin increases the absorption of drugs, sarsaparilla may be more than a mere flavoring vehicle and should be assayed for its saponin content. The hemolysis method seems to give satisfactory results; but if accepted as assay method for the official prepns., further experimentation will be required to standardize it. Results are reported giving the relative values of a no. of [illegible] and also fluidexts. and syrups of sarsaparilla. The "hemolytic index" showed that the variability of the [illegible] products on the market is so great that if the medici[illegible] and effect of the prepns. depended upon it, physicians might easily lose confidence in them. A. Papineau-Couture

A monograph for Ringer's solution as a solvent. Norman Pinschmidt and John C. Krantz, Jr. *J. Am. Pharm. Assoc.* **29**, 28–30(1940).—A formula and monograph for a physiol. salt soln. as a solvent for parenteral use are proposed for the National Formulary. A. P.-C.

Review of tentative changes in the ampoule monographs of the National Formulary. R. K. Snyder and E. N. Gathercoal. *J. Am. Pharm. Assoc.* **29**, 30-3(1940). A. Papineau-Couture

Decomposition rate of ethyl nitrite in brown mixture, U. S. P. Edward Greenfield and H. Walter Kuhl. *J. Am. Pharm. Assoc.* **29**, 35(1940).—The decompn. rate of $EtNO_2$ in brown mixt., U. S. P., is so rapid and extensive as to render it valueless in the latter prepn. A. P.-C.

Dry Moroccan roses. G. Igolen. *Parf. France rev. marques* **17**, 175–6(1939).—Steam distn. of dry Moroccan roses gave a 0.03% yield of a green essential oil, solid at ordinary temp. and having the following consts.: d_{15} 0.8628, α_D 0°, n_D^{45} 1.4627, f. p. 27°, m. p. 28.7°, acid value 19.6, ester value 35.07, ester value after formylation 68.74, rhodinol 19.80%. On being treated with petr. ether (b. 62–70°) the oil yielded a very dark green, semisolid concrete with acid value 18.2, ester value 64.4, m. p. (Pohl) 46–7°. Treatment of the concrete by the usual method gave a viscous, very green absolute with acid value 28, ester value 70. Steam distn. at atm. pressure of 3 kg. of the solid oil, with cohobation for 4 days, yielded 31.5 g. (1.05%) of green essential oil, having the following characteristics: d_{15} 0.8666, α_D^{20} −0°20′, n_D^{20} 1.4637, f. p. 11°, acid value 16.8, ester value 39.2, ester value after acetylation 129.06, ester value after formylation 105.21, rhodinol 30.90%, reduces ammoniacal $AgNO_3$; on oxination, 1 cc. of the oil requires 1.3 cc. 0.5 *N* KOH. The oil contains 26.8% stearoptenes (Gildemeister's method). The following were found in the oil: eugenol, pelargonic and phenylacetic acids, (probably) nonanal, benzaldehyde, geraniol and rhodinol. A. Papineau-Couture

The chemistry of sulfanilamide and sulfapyridine. C. C. Lucas. *Bull. Acad. Med. Toronto* **13**, 103–107 (1940). J. Pinchack

Crystalline zinc insulin with protamine. A preliminary note on a newer insulin modification. Barnett Greenhouse. *Conn. State Med. J.* **4**, 78–82(1940). A newer insulin modification is presented in which the protamine is combined with a soln. of Zn insulin crystals as a base instead of the amorphous insulin with Zn, as in the com. protamine Zn insulin. One cc. of the suitably buffered protamine soln. contg. 2.5 mg. protamine per cc. added to 4 cc. U-50 cryst. Zn insulin yields a U-40 diln. There is 5–10 times less Zn in this prepn. than in com. protamine Zn insulin. The new prepn. is clinically identical with the com. product both in appearance and effect, but is superior to the latter in that it is nonallergic. J. Pinchack

Vitamin cosmetics. M. G. de Navarre. *Progressive Perfumery & Cosmetics* **1937**, 10–11.—A discussion of skin absorption of vitamins, natural *vs.* synthetic vitamins, the skin vitamin (possibly vitamin A or D or a mixt. of both), vitamin-cream formulation, and the use of vitamin F in cosmetics. Leopold Scheflan

The newest stage in liquid shampoos. J. W. Orelup. *Progressive Perfumery & Cosmetics* **1937**, 12–14.—A discussion of the properties important in shampoos and of the new types of shampoo that have been developed by the use of new types of wetting, foaming, detergent and emulsifying agents. Leopold Scheflan

Protection against sunburn. Ernst Ohlsson. *Progressive Perfumery & Cosmetics* **1938**, 18–20.—The wave lengths of sunlight that are destructive to the skin lie in the region 2920–3200 A. A protective agent should absorb not less than 75% of the rays in this region, should not absorb longer waves, should be stable in sunlight in a thickness of 0.02 mm., and should be nontoxic and physiologically inactive. Various chem. mixts. were tested

with the Orelup radiometer. A mixt. of 0.4% diphenylbutadiene, 0.6% stilbene and 0.45% cinnamic acid gave about 90% absorption for the wave lengths 3500–3400 A. However, it is unstable in sunlight, entirely losing its absorptive power after about 5 min. The skin test must be made in the sun, under the same conditions under which the prepns. are to be used. Leopold Scheflan

Improving the soap shampoo. J. W. Orelup. *Progressive Perfumery & Cosmetics* **1938**, 21–2, 28–9.—Ordinary liquid soap shampoos contain 20–30% soap. The shampoo can be improved greatly by reducing the soap concn. and adding about 5% of the new detergents. While 5% is insufficient to inhibit the formation of Ca and Mg soaps when the shampoo is used with hard water, it will keep them in a colloidal state so that they can be washed out readily. The addn. of the new detergents keeps the stearates and palmitates in soln. The chemistry and production of sulfonated-oil shampoos is discussed briefly. Leopold Scheflan

Establishing the value of sunburn preventive material. Ernst Ohlsson. *Progressive Perfumery & Cosmetics* **1938**, 26–8.—Detailed description of the use of the Orelup radiometer. Leopold Scheflan

The modern bath oil. J. W. Orelup. *Progressive Perfumery & Cosmetics* **1938**, 34–5.—The use of the newer colloidal detergents, e. g., Intramine C, with sulfonated oil improves the properties and stabilizes the sulfonated oil. Intramine C, which is a good dispersing agent, should be used in the proportion of 2 parts to 3 parts of the sulfonated castor oil. Leopold Scheflan

Formulating sunburn preventive preparations. Ernst Ohlsson. *Progressive Perfumery & Cosmetics* **1938**, 35–7. Preventives for sunburn usually contain fluorescent substances that convert ultraviolet to visible rays in the violet or blue region. Among suitable fluorescent compds. are esculin, esculetin, umbelliferone, and esters and other substitution products of anthranilic acid. Screening materials that depend mainly on absorption or invisible fluorescence for their protective action include the salicylates, cinnamates and certain fatty oils. Coconut oil absorbs 23% of the ultraviolet spectrum, peanut oil 24, olive oil 23, poppyseed oil 23, cottonseed oil 26, and sesame oil 39%. The inclusion of preservatives and antioxidants prevents oxidation and rancidity. The addn. of a small amt. of cholesterol tends to increase pigmentation and facilitate the tanning of the skin in the sun. Methods of prepn. of such products are described briefly. L. S.

The relationship of the chemistry of perfumes to other branches of the organic chemical industry. S. Isermann. *Progressive Perfumery & Cosmetics* **1938**, 37–8.—A brief survey with particular consideration of benzaldehyde, coumarin, artificial geranium, vanillin and naphthalene. Leopold Scheflan

Factors in sunburn. Ernst Ohlsson. *Progressive Perfumery & Cosmetics* **1938**, 45–6.—The photodynamic or photosensitizing agents increase the sensitivity of the skin to the action of ultraviolet rays. Examples are hematoporphyrin, certain essential oils (citrus oil, oil of bergamot) and dyes (eosine); these should not be present in prepns. for prevention of sunburn. Emulsifiers contg. soaps made from fixed alkalies tend to increase the erythemal action of the sun, probably owing to hydrolysis in the sunlight with liberation of the alkali. Hence, ordinary vanishing creams contg. K stearate should not be employed; an org. base such as triethanolamine is to be preferred to a fixed alkali for such creams. Leopold Scheflan

The gist of protection against sunburn. Ernst Ohlsson. *Progressive Perfumery & Cosmetics* **1938**, 51–2.—Violuric acid in very dil. solns. gives only partial protection at 2900 A. By adding dil. solns. of similar compds. having absorption peaks at 3100 and 3200 A., a mixt. is obtained that absorbs the entire hazardous range with the exception of a narrow band at 2900 A., which can be screened out by the addn. of either uric or cinnamic acid. Such screening materials can be incorporated in oils, creams, liquid emulsions, water lotions and alc. lotions. L. S.

The efficacy of vitamin F. Maison G. de Navarre and Richard J. Maicki. *Progressive Perfumery & Cosmetics* **1938**, 58–9.—A discussion of use in cosmetics, unit potency and the 1:1:3 cholesterol-lecithin-vitamin F ratio. Leopold Scheflan

Skin food. Ernst Ohlsson. *Progressive Perfumery & Cosmetics* **1938**, 59–60, 66–7, 77–8, 84–5, 91–3, 101–2, 108–11.—A discussion of the skin and its constituents, the use of cholesterol, oxycholesterol, ergosterol and other sterols, vitamin D and various bases, the nature and functions of substances that may directly or indirectly affect the skin, the chem. nature of lecithin and water-sol. vitamins B and C and their functions in the body and cosmetic possibilities, the nature and characteristics of proteins, hormones and lipides and their effects on life processes, applications of lipide derivs. including higher alcs. to cosmetics, the transmission of "skin food" into the skin, the process of tissue culture and the significance of the amino acids in cell life. Leopold Scheflan

The fixing of perfumes. S. Isermann. *Progressive Perfumery & Cosmetics* **1938**, 50–1; cf. following abstr.—The fixing of a perfume is mainly a phys. process although chem. reactions are contributing factors. Fixatives are enumerated which (1) are odorless or practically so, (2) have an odor and accentuate the other odors in the mixt. without changing the characteristic of the principal ingredient, (3) have a tendency to develop the bouquet, (4) make it difficult to imitate the mixt. Leopold Scheflan

Fixatives. S. Isermann. *Progressive Perfumery & Cosmetics* **1938**, 68–70, 83–4, 94–5, 103; **1939**, 118, 123–4.—Sp. suggestions are offered as to the fixatives to be used for fixing rose, jasmin, heliotrope, lilac and lily of the valley, carnation, gardenia, narcissus, violet, bouquet-type odors, oriental types, amber types and spicy odors and for the use of fixatives generally, particularly of gums and gum resins; flexibility in fixations, the faculty possessed by some odors of acting as their own fixatives is discussed. Theories of the action of fixatives in cosmetic prepns. are discussed. Leopold Scheflan

The background for the development of American perfume bases and cosmetics. S. Isermann. *Progressive Perfumery & Cosmetics* **1938**, 75–6, 86–7.—A discussion of production and of the status of the U. S. as a source of perfumery raw materials. Leopold Scheflan

Adaptations of the new surface-active materials to cosmetics. J. W. Orelup. *Progressive Perfumery & Cosmetics* **1938**, 78–9.—A review. Leopold Scheflan

The effect of hard water on cosmetics. Benjamin Kapp. *Progressive Perfumery & Cosmetics* **1938**, 107–8.—Water softened by ordinary methods cannot be employed in the prepn. of cosmetics because sol. electrolytes remain which interfere with emulsions. A wetting agent of the Intramine type minimizes the detrimental effect of water hardness as it forms water-sol. Ca and Mg salts, removes deposits of insol. metallic soaps and increases the detergent action, penetration and emulsification properties of the finished product. It is beneficial in various types of cosmetic prepns. Leopold Scheflan

The development of cosmetic creams. I. R. Hollenberg. *Progressive Perfumery & Cosmetics* **1939**, 115–16, 125–6, 139–40.—A survey of the evolution of the manuf. of cosmetic creams from about 150 A. D. to the present. Some theories on emulsions are described as well as methods of identifying the type of emulsion present in a cosmetic prepn. Leopold Scheflan

Molds and bacteria in cosmetics. Benjamin Kapp. *Progressive Perfumery & Cosmetics* **1939**, 116–18.—Deterioration of cosmetic prepns. by bacteria or molds can be prevented by the use of antioxidants, antiseptics, germicides and preservatives. Antioxidants should be sol. in the oil phase and insol. in the water phase. Preservatives should be sol. in either phase or both. Both antioxidants and preservatives should be compatible with all other ingredients in the formula, should not impair the potency of the other ingredients, must not change the characteristics of the finished product, must be nontoxic and non-irritating, should be practically odorless and colorless, should be effective in low percentages and their cost should be low in proportion to their effectiveness. Examples of antioxidants and preservatives are Peru balsam, Tolu

balsam, benzoic acid, Na benzoate, salicylic acid, gum benzoin, *p*-hydroxybenzoic acid and its Na salt and esters, Antranox M and Preservatol. Leopold Scheflan

The chemical constitution of oil of rose and its history from a chemical standpoint. S. Isermann. *Progressive Perfumery & Cosmetics* **1939**, 130–3, 140–3, 149–51.—A historical description of studies on stearoptene, geraniol and citronellol and a discussion of the structure, function and characteristics of other constituents of rose oil, namely nerol, linaloöl, phenylethyl alc., farnesol, EtOH, octyl aldehyde, nonyl aldehyde, citral and eugenol. Leopold Scheflan

Therapeutic asymmetric arseno compounds. Karl Streitwolf, Alfred Fehrle and Walter Herrmann (to Winthrop Chemical Co.). U. S. 2,180,778, Nov. 21. Compds. which are well tolerated when intravenously, subcutaneously or intramuscularly injected are made by reducing to asymmetric arsenobenzenes arsonophenoxyacetic acids or arylarsonic acids which have an imidazole ring contg. glycolic acid as substituent, together with other therapeutically active arylarsonic acids, or by producing the asymmetric arsenobenzenes according to known methods from the derivs. of the corresponding arsonic acids contg. trivalent arsenic and in cases in which the product to be obtained contains a primary amino group or groups, acylating such group or groups or causing the arsenobenzene to react with compds. capable of condensing with a primary amino group such as formaldehydebisulfite or glycide. Several examples with details are given. Cf. *C. A.* **33**, 7494[4].

Therapeutic extract of duodenal mucosa. Archibald B. Macallum and Nelles B. Laughton. U. S. 2,180,905, Nov. 21. An ext. which is suitable for the treatment of diabetes mellitus is obtained by extg. duodenal mucosa with an acidified alc. solvent, removing the solvent, extg. the residue with aq. acid, adding Ca acid phosphate to the soln., and pptg. the Ca acid phosphate, as by use of Na_2CO_3.

Therapeutic derivatives of pyrazinecarboxylic acid. Otto Dalmer, Claus Diehl and Eugen Walter (to Merck & Co.). U. S. 2,176,063, Oct. 17. Therapeutic compds. of relatively high stability and low toxicity are prepd. by the condensation of pyrazinecarboxylic acid hydrazide with aldehydes and ketones such as acetaldehyde, acetone, Me Et ketone, methylheptenone, trichloroacetaldehyde, biacetyl, Ph Me diketone, benzaldehyde and salicylaldehyde for the production of hydrazides of pyrazinecarboxylic acid: ethylidenehydrazide, m. 170–1°; isopropylidenehydrazide, m. 143–5°; isobutylidenehydrazide, m. 131–2°; isoöctylidenehydrazide, m. 70–1°; trichloroethylidenehydrazide, m. 180–1°; α-benzoylethylidenehydrazide, m. 145–6°; benzylidenehydrazide, m. 236–7°; and 2-hydroxybenzylidenehydrazide, m. 207–8°. Dipyrazinecarboxylic acid hydrazide, m. 223–5°.

Injectable preparations for lowering the blood pressure. Jenő Rakonitz. Hung. 122,712, Jan. 2, 1940. Aromatic nitro compds. contg. carboxyl, hydroxyl or other negative groups are emulsified in an oily medium. The COOH or OH groups may be esterified to increase the soly. Desensitizing substances contg. more than 7 C atoms are used as solvents or diluents.

Glucoside from Strophanthus kombe. Chemische Fabrik vorm. Sandoz. Fr. 840,965, May 8, 1939. A new cryst. glucoside, which contains one mol. of glucose more than *k*-strophanthin-β, is prepd. from the seeds of *Strophanthus kombe* (1) by dissolving an ext. of the seeds in an appropriate solvent, such as MeOH, EtOH or PrOH, pptg. the glucosides with a solvent immiscible with water, sepg. the ppts. and repeating the operation till the new glucoside is obtained; (2) by extg. (from the crude glucosidic prepn.) cymarin with $CHCl_3$, *k*-strophanthin-β with a mixt. of alc. and chloroform and crystg. the new glucoside, which remained in the mother liquor; (3) by acylating the ext. of the seeds or the seeds themselves, in presence of org. solvents such as pyridine, extg. the acylated glucoside and sapong. with an alkali or alk. earth alcoholate. The new glucoside is very sol. in water and lower alcs., insol. in ether and other solvents of fats, and crystallizes in a mixt. of MeOH-$CHCl_3$. It is used in therapy. Many examples are given.

Tertiary *N,N*-dicycloalkylalkylamines. Frederick F. Blicke. U. S. 2,180,344, Nov. 21. Compds., various of which are effective antispasmodics, of the general formula XXYN in which Y represents an alkenyl, alkyl, cycloalkyl, cycloalkylalkyl, aryl, or aralkyl radical and X represents a cycloalkylalkyl group in which the alkyl residue is attached to the N atom are substantially water-white, relatively viscous liquids of high b. p., which generally have a faint, characteristic, amine-compd. odor and form salts which are generally white cryst. solids, and may be prepd., e. g., by reacting a hydrocarbon-substituted primary amine such as methylamine with a cycloalkylalkyl halide in a liquid nonreactive org. solvent either at room temp. or by use of heat and pressure and reaction promoters such as NaOH, Na_2CO_3, K_2CO_3, $CaCO_3$, etc. Details are given of the production of: methylbis(cyclohexylmethyl)amine, b_{11} 144–7°; methylbis(β-cyclohexylethyl)amine, b_{23} 188–93°; methylbis(γ-cyclohexylpropyl)amine, b_{20} 202–4°; methylbis(δ-cyclohexylbutyl)amine, $b_{26.5}$ 225 7°; methylbis(β-cyclopentylethyl)amine, ethylbis(cyclohexylmethyl)amine, b_{12} 149–53°; ethylbis(β-cyclohexylethyl)amine, b_{21} 194–7°; ethylbis(δ-cyclohexylbutyl)amine, b_{19} 230–6°; ethyl(cyclohexylmethyl)(β-cyclohexylethyl)amine, b_6 146–9°; propylbis(β-cyclohexylethyl)amine, b_7 160–5°; isopropylbis(β-cyclohexylethyl)amine, b_7 171–4°; butylbis(β-cyclohexylethyl)amine, b_7 176–8°; amylbis(β-cyclohexylethyl)amine, b_7 178–181°; heptylbis(β-cyclohexylethyl)amine, b_6 197–202°; cyclohexylbis(β-cyclohexylethyl)amine, b_5 190–3°; phenylbis(β-cyclohexylethyl)amine, b_6 213–218°; benzylbis(β-cyclohexyl-

ethyl)amine, b_8 207–210°; and allylbis(β-cyclohexylethyl)amine, b_4 170–2°, and their hydrochlorides, etc. 1

Oxidation products of sterols containing two ketonic groups. Chinoin Gyogyszer és Vegyészeti Termékek Gyára R. T. (Kereszty és Wolf). Fr. 840,962, May 8, 1939. Sterols and their derivs. which contain free OH groups and whose carbon skeleton, contg. carbon atoms 1–22, is identical with those of cholesterol, allocholesterol or epicholesterol, are, after temporary protection of the double bond, oxidized by appropriate agents, such as permanganates or chromic acid to products contg. two keto groups. After restoration of the double bond, the reaction mixt. is freed by fractional crystn. or by extn. with two solvents, one miscible with water and one immiscible, from by-products, such as the sterol deriv. oxidized at carbon atom 3, and then subjected to chromatographic purification, with benzene as a solvent and Al oxide as adsorbant. The benzene filtrate, which contains all of the product contg. two ketonic groups not absorbed by Al_2O_3, is evapd., the residue dissolved in petr. ether and subjected, after addn. of an indicator such as Sudan III, to a chromatographic sepn. with Al_2O_3 as adsorbent. The product contg. two ketonic groups is completely adsorbed by the Al_2O_3 column, androstenedione in the upper zone and corpus luteum in the middle zone. They are extd. by ether or alc. The purification can be carried further by repeating the chromatographic sepn., using a mixt. of petr. ether and C_6H_6 as solvent (androstenedione is adsorbed, while corpus-luteum hormone passes into the filtrate), or by conversion to semicarbazones and fractional crystn. Many examples are given. 2 3 4

Ketones of the cyclopentanopolyhydrophenanthrene series. N. V. Organon. Fr. 840,994, May 8, 1939. In presence of alkali or alk. earth metals, the satd. or the unsatd. derivs. of allocholanic or etiocholanic acids, which may carry oxygen in their cyclic system, are condensed with compds. of the general formula $R'R''CHCO_2R$, where R′ and R″ are hydrogen, alkyl, alkoxyl or an esterified carboxyl, and R is alkyl. The condensed products are sepd. from the reaction mixt., sapond. and decarboxylated. 5

Cyclic ketones of the cyclopentanopolyhydrophenanthrene series. Soc. pour l'ind. chim. à Bâle. Fr. 840,854, May 3, 1939. The ketones, satd. or not, are obtained by transforming the free secondary carbinol groups of the ring into ketone groups, in compds. of cyclopentanopolyphenanthrene series, which contain side chains with multiple bonds in position α, β or β, γ with respect to the ring. After reducing, if necessary, the triple bonds to double, the compds. are treated with oxidation agents, such as permanganate or chromic acid in glacial acetic acid, or with dehydration agents, such as compds. with a carbonyl group in presence of metallic alcoholates (acetone or cyclohexanone in presence of butylate or propylate of Al, Cu or Pb). With unsatd. cyclic compds., it is often necessary to add a halogen or a halogen acid, in order to protect temporarily the double bonds in the ring. Among examples, 0.5 part of 17-ethinyl-$\Delta^{5,6}$-androstene-3,17-diol in 10 parts of acetone is added to a soln. of 1 part of Al butylate in 40 parts of toluene, the whole is refluxed for 2 hours and heated to the b. p., then dild. with 100 parts of ether and washed with an aqueous soln. of a mineral acid. The evaporation of the solvents leaves a ethinyl-$\Delta^{4,5}$-androstene-17-ol-3-one, melting at the temp. of 270–272°. 6 7 8

Nutrient amino acids. Kenneth S. Kemmerer (to Mead Johnson & Co.). U. S. 2,180,636, Nov. 21. A process of prepg. a nutrient material suitable for oral, rectal and intravenous administration, contg. all of the amino acids resulting from the hydrolysis of a highly purified protein material such as casein, involves washing acid-pptd. protein with acidified water until free from inorg. salts, refluxing the washed protein with an inorg. acid such as H_2SO_4, HCl or H_3PO_4, heating the hydrolyzed material to 82–105°, dilg. with water, adding $Ba(OH)_2$ sufficient to neutralize the hydrolytic agent, adding activated carbon, filtering, concg. in a vacuum, carefully adding addnl. $Ba(OH)_2$ for complete removal of the hydrolytic agent and inorg. acid, adding H_2S to ppt. heavy metals, filtering, concg. and drying. U. S. 2,180,637 relates to a process for prepg. a product of generally similar utility which may involve prepg. a mixt. of water 5 qts., highly purified casein 1 lb., Na_2CO_3 20 g., and pancreas 3 lbs., adding a mixt. of toluene 2 gals. and $CHCl_3$ 1 gal. for each 200 gals. of the initial mixt. (the Na_2CO_3 being sufficient to maintain a pH of 6 to 9) digesting the material at a temp. of about 38° to effect practically complete hydrolysis of the protein, adding another portion of pancreas and continuing the digestion until there is no increase, from day to day, in the amino N content and protein tests are negative, adding an amt. of acid chem. equiv. to the Na_2CO_3 used, adding decolorizing carbon, boiling for a short time, filtering and drying the filtrate. 9

Phenylmercuric citrate. Ralph P. Perkins (to Dow Chemical Co.). U. S. 2,181,098, Nov. 21. This compd. is made by heating phenylmercuric hydroxide with citric acid and is a white powder decompg. 200–204°, highly *germicidal*.

3,7-Diamino-9,10-dialkylphenanthridinium halides (antiseptics). Walter G. Christiansen and Wm. Braker (to E. R. Squibb & Sons). U. S. 2,176,889, Oct. 24. Details are given of the production of 3,7-diamino-9,10-dimethylphenanthridinium chloride (reddish brown crystals), 3-amino-9-((p-dimethylaminophenyl)iminomethyl)-10-methylphenanthridinium chloride (m. 119–21°), and of the intermediates: 3,7-dinitro-9-methylphenanthridine, 3,7-diamino-9-methylphenanthridine, 3,7-diacetamino-9-methylphenanthridine, 3,7-diacetamino-9,10-dimethylphenanthridinium sulfate.

Allantoin ointment. Frederick R. Greenbaum (to National Drug Co.). Can. 386,238, Jan. 9, 1940. Stearic acid is melted at water-bath temp. and held at 70°, 40 g. of allantoin crystals is separately dissolved in 500 cc. distd. water heated to slightly below the b. p., glycerol 400 and triethanolamine 20 g. are added, the temp. is raised to 70° and the mixt. poured slowly with stirring into the stearic acid until a white uniform ointment is obtained to provide triethanolamine stearate 60 and excess $C_{18}H_{36}O_2$ 590 g.

Tetracyclic condensation products. I. G. Farbenind. A.-G. Fr. 841,080, May 10, 1939. The products are obtained by treating γ-(1-naphthyl)-butyric acid halide with CH_2N_2 to form corresponding diazoketones, transforming the group $—CH_2-N_2$ of the diazoketones, by the action of HBr, into $—CH_2$-halogen, and condensing the latter with metallic derivs. of α-malonic acid ester or of an acetoacetic ester to form esters of the corresponding keto acids. The esters after sapon. and eventually re-esterification, are subjected to a ring closure operation by means of condensing agents, such as H_2SO_4 or $SnCl_4$, in the latter case, after transforming the acid group into acid halide. The naphthalenic ring and the acid radical of γ-(1-naphthyl)butyric acid may be partly substituted by alkoxy groups. Among examples, γ-(6-alkoxy-1-naphthyl)-α-methylbutyric acid, treated according to the method, yields, as a final product, a hydroxy ketone with great estrogenic activity.

Water-soluble gold complexes of keratin degradation products. Shering-Kahlbaum A.-G. Fr. 840,958, May 8, 1939. See Ger. 663,854 (*C. A.* **33**, 3204).

Degradation products of sterols. Lothar Strassberger and Helmut Jacobi (to Schering Corp.). U. S. 2,180,095, Nov. 14. Compds. such as cholesterol acetate dibromide, sitosterol acetate dibromide or stigmasterol acetate dibromide are oxidized with chromic acid and the resulting mixt. is poured into water, extd. with ether and the ethereal soln. shaken with 2 *N* aq. NaOH soln. The ppt. formed is filtered off and suspended in ether and the ethereal suspension is acidified with dil. H_2SO_4, sepd. from aq. acid and evapd. to dryness. The residue is dissolved in glacial HOAc, debrominated with Zn dust and heated on a water bath; the soln. is evapd. to dryness and the residue is triturated with MeOH, and, on crystn., products are obtained such as 3-hydroxycholenic acid, m. about 232°, 3-hydroxynorcholenic acid, m. about 240–2°, or 3-hydroxybisnorcholenic acid, m. 295–302°. Other products obtained are: 3-acetoxycholenic acid methyl ester, m. 154–

5°; 3-acetoxynorcholenic acid methyl ester, m. 240–2°; 3-acetoxycholenic acid, m. 183–4°; and 3-acetoxynorcholenic acid. Various of these products may be used as intermediates in producing male sex hormones, dehydroandrosterone, the corpus luteum hormone, pregnendione, bile acids, etc.

Perspiration accelerators for application to the skin. Edward E. Henderson and David O. Meeker (to Cutasy Laboratories, Inc.). U. S. 2,180,280, Nov. 14. A mineral oil 45–70, petrolatum 13–25, and waxes such as paraffin, spermaceti, ozocerite or beeswax 20 35% are used together.

Removing gases from organic liquids such as oils, as in preparing them for molecular distillation. Kenneth C. D. Hickman (to Distillation Products, Inc.). U. S. 2,180,051, Nov. 14. In prepg. a vitamin concentrate by high-vacuum distn. of a fish oil contg. vitamin and also absorbed gases which would cause at least partial oxidation and thermal destruction of the vitamin during distn., the absorbed gases and oxidizing substances are removed from the oil previous to distn. by subjecting the oil in a thin film to extreme agitation and to a pressure of less than about 0.005 mm., until the internal pressure of the gas in the oil is below about 0.015 mm. An app. with rotating plates may be used.

***l*-Ascorbic acid.** Franz Elger (to Hoffmann-La Roche Inc.). U. S. 2,179,977, Nov. 14. 2-Keto-*l*-gulonic acid or a deriv. such as the methyl ester is heated in a soln. of acid reaction (suitably in a mixt. of EtOH and $CHCl_3$ with HCl). U. S. 2,179,978 relates to a process in which 2-keto-*l*-gulonic acid or a deriv. such as the methyl ester is heated with an alkali salt of a weak acid such as $NaHCO_3$ or NaOAc in substantially anhyd. alc. soln. such as MeOH.

Vitamin D concentration. Sidney E. Miller (to General Mills, Inc.). U. S. 2,179,560, Nov. 14. Material contg. either natural or synthetic vitamin D is dissolved in an org. solvent such as C_6H_6 or ether and the soln. is passed through a mass of activated tri-Ca phosphate which adsorbs a major portion of the vitamin D; the phosphate is washed with an org. solvent and the vitamin D is sepd. by distg. off the solvent.

Vacuum distillation of fish oils containing vitamins. Kenneth C. D. Hickman (to Distillation Products, Inc.). U. S. 2,180,356, Nov. 21. A process of mol. distn. of fish oils to obtain concd. fat-sol. vitamins involves segregating components distg. up to 170°, sepg. a fraction at about 170 195° and returning it to the fresh incoming oil to be distd., and sepg. a fraction high in vitamin content at about 195–230°.

Condensation products of 1-methyl-1-cyclopenten-5-one with 1-vinyl-3,4-dihydronaphthalene, etc. Wilhelm Bockemüller (to Winthrop Chemical Co.). U. S. 2,179,809, Nov. 14. Condensation is effected by heating 1-methyl-1-cyclopenten-5-one (suitably used in excess in an inert atm. and at a temp. of about 200°) with compds. such as 2,3-dimethylbutadiene (forming trimethyltetrahydroindanone, b_{12} 129–30°) with 1-vinyl-1-cyclohexene (forming an oily product $b_{0.1}$ 104–5°), with 1-vinyl-3,4-dihydronaphthalene (forming a product $b_{0.05}$ 160–80°); and various details are given of the production of 1-vinyl-3,4-dihydronaphthalene, etc. Condensation products obtained may be used as *intermediates in the synthesis of hormone-like substances*, e. g., by the condensation of 1-methyl-1-cyclopenten-5-one with 1-vinyl-6-methoxy-3,4-dihydronaphthalene and sapon. of the methoxy group in the condensation product formed, estrone-like products are obtained.

Hexamethylenetetramine salts of aromatic acids. Monroe D. Edelman and Edmond T. Tisza (to Pyridium Corp.). U. S. 2,179,618, Nov. 14. Compds. suitable for use as *antiseptics* for the treatment of infections of the urinary tract are produced, such as methenamine phenylacetate, softening 80–90°, methenamine β-phenylpropionate, m. 124–5°, methenamine γ-phenylbutyrate, beginning to char at 205° but not m. up to 250°, methenamine cinnamate, m. 133–4°, and methenamine β-hydroxy-β-phenylpropionate, m. 141–3°, which are sol. in water, alc., $CHCl_3$ and benzene and insol. in ligroin. Various details of manuf. are given.

Stabilized bactericides. Walter G. Christiansen (to E. R. Squibb & Sons). U. S. 2,176,890, Oct. 24. A compn. of good stability comprises a slightly alk. soln. of a Hg deriv. of a substituted phenol such as (acetoxymercuri)nitro-*p*-*tert*-butylphenol together with gelatin, egg albumin, pectin, casein, lysalbinic acid or protalbinic acid.

Stable germicidal heteroatomic mercurimercapto compounds. Russel J. Fosbinder and Lewis A. Walter (to Maltbie Chemical Co.). U. S. 2,176,457, Oct. 17. By refluxing a mercaptopyridinecarboxylic acid in a solvent such as EtOH with an ethyl-, propyl-, butyl- or like mercuric chloride, products are obtained such as 2-(ethylmercurithio)-5-pyridinecarboxylic acid, 2-(propylmercurithio-5-pyridinecarboxylic acid, and 2-(butylmercurithio)-5-pyridinecarboxylic acid (details of the production of which are given and which all decompose when strongly heated). They may be used as antiseptics in aq. soln. and have the general formula $N.CH.C(CO_2M)\cdot CH\cdot CH\cdot CSHgR$, where R is an alkyl radical and M is H, alkali metal, alk. earth metal, NH_4, alkylammonium or alkanolammonium, being stable toward free oxygen even at elevated temps. and in the presence of metal ion catalysts.

Disinfectant. Richárd Müller. Hung. 122,466, Dec. 15, 1939. Gases satd. with Ag or with a Ag compd. are led through finely porous substances (diatomaceous earth, carbon, cotton, etc.). For use, the product is heated and pure air is led through it. This air contains disinfectant Ag particles.

Water-absorbing therapeutic and cosmetic creams. Neovasol Vegyipari Kft. (István Lajos Waldmann and Miksa Dénes, inventors). Hung. 122,444, Dec. 15, 1939. One or more hydrogenated animal or vegetable oils are mixed with disinfectants (e. g., salicylic acid, tricresol) and emulsifiers (e. g., cholesterol, alc. sulfonates), finally with aliphatic acids and water.

18—ACIDS, ALKALIES, SALTS AND OTHER HEAVY CHEMICALS

E. M. SYMMES

Optimum conditions for slaking of lime under steam pressure. V. I. Endovitskiĭ and A. B. Kvitnitskiĭ. *Trudy Khar'kov. Khim.-Tekhnol. Inst. S. M. Kirova* **1**, 51–61 (in English, 61–2) (1939).— On lab. scale the slaking of lime was complete in 25 min. under a pressure of 4.5 atm. The slaking of lime-sand mixts. in an autoclave under a pressure of 4.5 atm. was also complete in 25 min.
B. Z. Kamich

Conditions for the deposition of soda from the brines of the Mikhallov soda lakes. O. D. Kashkarov. *Byull. Inst. Halurgii* **1938**, No. 4, 22–47; *Khim. Referat. Zhur.* **2**, No. 4, 101–2 (1939).—The object of the expts. was to det. the optimum conditions for the deposition of soda and of the proper methods for its extn. Three methods were investigated: (*a*) crystn. with cooling, (*b*) solar evapn. and (*c*) flame evapn. Crystn. with cooling gives optimum results (90–3%). Up to 80% was obtained by this method when a purer product was desired. Considerable contamination of the product and low yields make flame evapn. the least successful. Solar evapn. gives low yields. Crystn. with cooling is less sensitive to the concn. change of the brine.
W. R. Henn

The industrial utilization of Sivash brine. A. S. Eliseev. *Byull. Inst. Halurgii* **1938**, No. 7, 32–9; No. 8, 32–47; *Khim. Referat. Zhur.* **2**, No. 4, 101 (1939).—Sivash brine is an important raw material for production of Br

and of Mg salts. The concn. varies from 2–4° to 12–14°Bé. $Mg(OH)_2$ can be pptd. from weak solns. The solns. may be preliminarily concd. in evaporators to a definite concn., or the natural solns. may be utilized. In natural evapn. of sea water in the sun, sepn. of $CaSO_4$ takes place at 26°Bé. and of NaCl at 32°Bé. Further concn. of the mother liquor yields the mixed salt NaCl and $MgSO_4$, KCl, $MgCl_2$ and, finally, $MgCl_2$ (bischoffite). The following scheme is proposed: Gypsum is sepd. from a 26°Bé. soln. in evaporators by an addn. of basic $CaCl_2$. After the pptn. of NaCl, the soln. (34°Bé.) contg. 13.9% of $MgCl_2$ and about 2.8 kg. of Br/cu. m. is first sent to the Br producing plant and later into the $Mg(OH)_2$ plant. The $Mg(OH)_2$ is obtained by adding CaO and a coagulant in the form of a pulp contg. 83% of water. A $Mg(OH)_2$ of high dispersity is obtained after roasting. The weak solns. are decarbonized with milk of lime, the Br is sepd., the soln. dild. to a weak concn., and $Mg(OH)_2$ sepd. by addn. of a weak milk of lime soln. W. R. Henn

Cinderella of the phosphates. R. E. Hall. *Rept. New Engl. Assoc. Chem. Teachers* **41**, 18–21(1939).—$NaPO_3$ in acid or alk. soln. and particularly at elevated temps. reverts to orthophosphate, suppresses the ionization of many metallic salts in soln., coagulates albumin (ortho- and pyrophosphate do not), has a high dispersive action and is very effective in causing stabilization of supersatn. of Ca salts, particularly $CaCO_3$. One to two p. p. m. of $NaPO_3$ added to a hard bicarbonate water will prevent pptn. of $CaCO_3$, while a water contg. 300 p. p. m. of hardness as $CaCO_3$ will not yield a ppt., even when treated with Na_2CO_3. In city water works, after-pptn. following the reduction of the hardness of water by treatment with lime can be avoided by the addn. of 1–2 p. p. m. $NaPO_3$. This "threshold treatment" also largely eliminates the deposition of scale in water heaters. Leopold Scheflan

Prepn. of strong and "superstrong" cooking acid (Eliashberg) **23**. Potassium metaphosphate (Madorsky, Clark) **15**. Apatites (Fiveg, Shubin) **8**.

Bernard, L. M.: Le mirage de l'iode. Paris: Soc. d'Editions géographiques, maritimes et coloniales. 169 pp. Fr. 36. Reviewed in *Chimie & industrie* **42**, 665 (1939); *Chem. Trade J.* **106**, 22(1940).—Iodine resources and industry are discussed.

Concentration of nitric acid. Frederick C. Zeisberg (to E. I. du Pont de Nemours & Co.). Can. 386,477, Jan. 23, 1940. Dil. HNO_3 is treated with H_2SO_4 in a dehydration zone, the residual acid elevated to the upper portion of a denitrating zone by direct contact of steam, the residual acid denitrated, and the weak HNO_3 vapors returned from the upper to the lower portion of the dehydration zone. An app. is described.

Sulfuric acid. Bernard M. Carter (to General Chemical Co.). U. S. 2,180,727, Nov. 21. An arrangement of app. is described, and a method for catalytically making SO_3 in a plurality of stages, which involves forming a gas mixt. contg. SO_2 and O in amt. by vol. less than that needed in practice for complete conversion of the SO_2, bringing the gas mixt. at a reactive temp. into contact with a first body of catalytic material of given cross-sectional area and of vol. substantially less than that normally employed when all the gases involved in the conversion reaction are passed through the first body of catalytic material, whereby part of the SO_2 is oxidized to SO_3, the temp. of the gas mixt. increased and the O content diminished, introducing further quantities of oxidizing gas at relatively low temp. into the partially oxidized gas mixt. to cool it to approx. initial conversion temp. and to supply O needed for oxidation of further amts. of SO_2, whereby the gas volume is substantially increased, and then passing the resulting gas mixt. in contact with a second body of catalytic material having a cross-sectional area greater than the area of the body of catalytic material of the preceding stage in direct proportion to the increase in gas volume between the stages.

Sulfuric anhydride. James B. Castner (to Canadian Industries Ltd.). Can. 386,314, Jan. 16, 1940. The air required for producing SO_2 for SO_3 manuf. is predried by activated alumina or SiO_2 gel or a mixt. of the two. An app. is described.

Recovery of sulfur dioxide from gases. Raymond F. Bacon. U. S. 2,180,495, Nov. 21. App. for absorption treatment of a gas contg. SO_2 with a liquid medium such as an aq. soln. of borax and boric acid comprises an absorption chamber, a stripping chamber at a lower elevation, means for introducing a liquid absorption medium into the absorption chamber, a conduit connecting the absorption chamber with the stripping chamber, means for liberating absorbed SO_2 within the stripping chamber, means for collecting SO_2, and means for returning absorption medium after stripping to the absorption chamber. All parts of the app. are so designed that stoppage will not be caused by finely divided solid that is pptd. during the process. Cf. *C. A.* **33**, 3082[8].

Preparation of pure alkali salts of acids of a high degree of oxidation. I. G. Farbenind. A.-G. Fr. 849,849, May 3, 1939. An acid-forming element, or a compd. of the element in a lower state of oxidation, is heated in the presence of O with an alkali oxide, or in the presence or absence of O with an alkali peroxide. In examples (1) 1 mol. Fe_2O_3 is heated, in an atm. of O or air free from CO_2, with 6 mols. Na_2O to form Na_6FeO_6; (2) 1 mol. NaI heated to 300–600° with 2 mols. Na_2O_2 in an atm. of O or air forms Na_5IO_6; (3) 1 mol. of Bi_2O_3 with 3 mols. of Na_2O in an atm. of O or air free from CO_2 and H_2O, at 500° forms Na_3BiO_4; (4) 1 mol. PbO in O free from CO, with 2 mols. Na_2O forms Na_4PbO_4; and (5) 1 mol. Pr_2O_3 in O with 2 mols. Na_2O at 400° forms Na_2PrO_3.

Alkaline earth metals. Frank R. Kemmer. U. S. 2,179,823, Nov. 14. A mixt. of Al and a finely divided material contg. an alk. earth metal oxide such as MgO is heated to a temp. above the m. p. of Al and below the b. p. of the alk. earth metal, the heated mixt. is evacuated, and an inert gas such as H, He or CH_4 is admitted to the evacuated mixt. so as to force molten Al into intimate assocn. with the material; the mixt. is then heated to the temp. of volatilization of the alk. earth metal and the latter is distd.

Water-soluble titanium compounds. Edward N. Kramer (to E. I. du Pont de Nemours & Co.). U. S. 2,180,961, Nov. 21. For producing solubilized Ti values, a residual Ti-contg. product from the clarification stage of a Ti-oxide-producing operation is treated with H_2SO_4 of such strength (suitably about 85% or higher) as substantially completely to convert the Ti content of the residue to the sulfated condition, and the resultant acid-Ti sulfate mixt. is utilized in effecting solubilization of a Ti ore.

Aluminum chloride. Wm. H. Shiffler and Ward P. Anderson (to Standard Oil Co. of Calif.). U. S. reissue 21,265, Nov. 14. A reissue of original patent No. 1,887,566 (*C. A.* **27**, 1458).

Ammonium thiocyanate. Roger A. Mathes (to B. F. Goodrich Co.). U. S. 2,179,943, Nov. 14. A suspension of NH_4 dithiocarbamate in a neutral, nonionizing, org. solvent such as toluene or benzene, in which the product is practically insol., is heated to a temp. not over about 100° until evolution of H_2S is complete.

Calcium cyanamide. Ernst Winter and Herbert Polack (to Akt.-Ges. für Stickstoffdünger). U. S. 2,180,382, Nov. 21. See Ger. 677,275 (*C. A.* **33**, 6732[4]).

Granular calcium hypochlorite. Homer L. Robson and Harold D. Kaufmann (to Mathieson Alkali Works). Can. 386,058, Jan. 2, 1940. Moist $Ca(ClO)_2$ is formed into curved flakes, 0.01–0.03 in. thick, dried and crushed between yielding-surfaced rolls, 2–4 in. in diam., to produce grains of minus 20 mesh. An app. is described.

Pure iron oxides. János Nagy. Hung. 122,496, Dec. 15, 1939. Substances contg. Fe oxides are treated with sulfuric acid or NH_4 sulfate, the insol. part is sepd. and the soln. is treated with ammonia in 2 or 3 fractions. In the first fraction sufficient ammonia is added to ppt. metal hydroxides that ppt. more readily than Fe hydroxide. After the sepn. of the ppt., a 2nd ammonia treatment ppts. iron as hydroxide. After filtration a 3rd treatment

with NH_3 seps. metal hydroxides pptg. less readily than Fe hydroxide. The remaining soln. can be regenerated by crystn. and used again.

Lead arsenate. James W. Swaine (to General Chemical Co.). Can. 386,481, Jan. 23, 1940. Pb oxide and H_3AsO_4 are fed into a reaction zone contg. catalyst and made to react during an initial phase, in which a pH not above 8 and higher than induced by the catalyst is maintained. In the second phase the major portions of the reactants are fed into the resulting reaction mass in amts. regulated to keep the pH lower than induced by the catalyst and not less than about 1.5.

Ammonia-soda process with production of a pure caustic soda. John C. Garrels and Howard Roderick (to Michigan Alkali Co.). U. S. 2,180,755, Nov. 21. In the operation of the ammonia-soda process in which carbonic acid compds. are formed and lime is treated with NH_4Cl soln. for recovery of NH_3, leaving a $CaCl_2$ soln., the latter is clarified, the carbonic acid compd. of the process is treated with the $CaCl_2$ soln. to form $CaCO_3$, the $CaCO_3$ is calcined and the product is treated with Na_2CO_3 in the presence of water to form NaOH and $CaCO_3$, followed by filtering, drying and returning the last produced $CaCO_3$ to the cycle and sepg. of the NaOH in pure form.

Hydrated sodium tetrasilicate. Walter F. Wegst and John H. Wills (to Philadelphia Quartz Co.). U. S. 2,179,806, Nov. 14. A Na silicate soln., contg. more SiO_2 than is represented by the mol. ratio of $1Na_2O$ to $2SiO_2$ and contg. not substantially more than about 75% of water, is seeded with crystals having a mol. ratio of Na_2O to SiO_2 of 1 to 4 and contg. approx. 7 mols. of water.

Tetrazylazide and its salts. Walter Friederich and Karl Flick (to Dynamit-A.-G. vorm. Alfred Nobel & Co.). U. S. 2,179,783, Nov. 14. For the production of tetrazylazide and its salts, cyanogen halides are treated with a soln. of hydrazoic acid, an alkali metal azide or an alk. earth metal azide.

Titanium gluconate. Titan Company Inc. Fr. 840,907, May 8, 1939. To a soln. of titanyl sulfate (orthotitanic acid dissolved in sulfuric acid $TiO_2:H_2SO_4 = 1.1$) is slowly added powd. alk. earth gluconate. Water is then added to dissolve the titanium gluconate formed by the reaction. Alk. earth sulfate is sepd. by filtration or decantation, and the titanium gluconate is extd. from the soln. by an org. agent, preferably MeOH.

Vanadium oxide catalyst suitable for use in various oxidation processes. Harold B. Foster (to National Aniline & Chemical Co.). U. S. 2,180,353, Nov. 21. A catalyst carrier such as pumice or alundum, is assocd. with a compd. prepd. by reducing an O-contg. pentavalent V compd. such as metavanadic acid, with HCl, HBr or HI and subsequently igniting the resulting mixt.

Working up gas mixtures rich in krypton. Egyesült Izzólámpa és Villamossági R.T. Hung. 122,516, Dec. 15, 1939. The oxygen of the gas mixts. obtained by evapn. of liquefied gases is used to oxidize the combustible components of the gas mixt. The remaining O is removed by oxidation of solid combustibles in suitable app.

Sorptive carbon. Victor C. Hamister (to National Carbon Co.). U. S. 2,180,735, Nov. 21. App. is described, and a process for producing sorptive carbon, which involves forming a composite body contg. carbonaceous material, such as cocoanut charcoal, and a metal carbonate, such as limestone, which is decomposable at temps. of about 700° (the carbonate being nonuniformly distributed in the body, as by suitable placement in clay saggers) and heating a region of the body to above 700° where the proportion of carbonate is relatively low, so as progressively to liberate CO_2 from the carbonate and partially oxidize the carbonaceous material.

19—GLASS, CLAY PRODUCTS, REFRACTORIES AND ENAMELED METALS

G. E. BARTON AND C. H. KERR

Glass as a chemical engineering material. I. Some recent developments. R. Quarendon. *Ind. Chemist* **16**, 9–14(1940); cf. *C. A.* **33**, 4825⁶. G. G.

Manufacturing lime for the glass industry. A. H. Nieman. *Am. Soc. Testing Materials, Symposium on Lime* **1939**, 32-5(1940).—Both burned lime and raw limestone are used in glass manuf.; the former still predominates. Lime should be hard burned and of uniformly high quality, low in Fe and $SrSO_4$; S is an undesirable impurity frequently taken up from the fuel in burning. Various finenesses are required, No. 10 to dust, in both lime and limestone; hydrate finds some use when an extremely fine product is desired. C. J. Schollenberger

Batch materials, old and new. Alexander Silverman. *Am. Glass Rev.* **58**, No. 53, 3 pp. (1939)(reprint).—An outline of batch materials is given in alphabetical order of the chem. elements. G. G.

Quantitative spectrochemical analysis of boric oxide in glass. II. Kenzo Harai. *J. Chem. Soc. Japan* **60**, 1159–60(1939); cf. *C. A.* **34**, 231⁸.—It has been confirmed that the presence of a small quantity of PbO does not affect the result of the analysis. T. Katsurai

New Uviol glass of the binary system CaF_2–SiO_2. Choong Shin-Piaw. *J. Chem. Phys.* **8**, 129(1940).—Glassy beads contg. 70–79% CaF_2 and 21–30% SiO_2 were prepd. The d. is 2.80–2.90. The m. p. is 1460°. The limit of transparency is about 2050 A.; it varies irregularly with the d. G. M. Petty

Sodium fluosilicate for the production of frosted glasses. F. H. Zschacke. *Sprechsaal* **72**, 583–4, 591–2(1939).—Na_2SiF_6 is successfully used for frosted glasses instead of cryolite. Part of the F should be added as CaF_2. Al_2O_3 and too much $CaCO_3$ are detrimental to frosting, Sb_2O_3 and ZnO favor frosting and good colors, while BaO is good instead of CaO, but not good in all cases. J. M. Noy

Rapid determination of the moisture content of clay and ceramic materials. I. E. Dudavskiĭ and L. E. Medvedeva. *Soviet Geol.* **9**, No. 7, 54–61(1939).—The materials are immersed in paraffin, which is then heated to 130–50°, and the loss in wt. is detd. F. H. Rathmann

New Thermofor kiln and clay-regeneration processes for maintaining decolorizing clays at high efficiencies. T. P. Simpson and John W. Payne. *Natl. Petroleum News* **31**, R-486–92; *Refiner Natural Gasoline Mfr.* **18**, 438–43, 455; *Oil Gas J.* **38**, No. 27, 147, 150, 152, 154, 156, 159(1939).—The kiln consists of heat-transfer tubes in a stationary jacket. Angle iron is stacked between the tubes with the apexes upward, to conduct heat to the tubes. Air is supplied to the bottom and spent clay fed at the top. Circulation of molten metal or salt through the tubes controls the temp. The carbonaceous matter of the clay supplies the heat for regeneration. C. H. Brooks

New process for the intensive preparation of heavy ceramic masses. Adolf Möser. *Ziegelwelt* **70**, 179–83 (1939); *Chem. Zentr.* **1939, II**, 2266.—The following are discussed: working with heated moistened masses; direct steam treatment of the mass and deairing; steam "conversion," high-pressure silos; conversion by expansion of enclosed air with simultaneous steam treatment. M. V. Condoide

Technological and physicochemical properties of grog at different degrees of firing. A. I. Kramarenko. *Trudy Kharkov. Khim.-Tekhnol. Inst. S. M. Kirova* **1**, 63–87 (in English, 87–88)(1939).—Al_2O_3 and Fe_2O_3 are easily sepd. from grog fired at 600–900° when heated with 6% HCl; however, addns. of amorphous SiO_2 and Fe_2O_3 retard the sepn. The Al_2O_3 of grog reacts on firing not as a part of the clay complex but chiefly as Al_2O_3, in the firing interval 600–800°. No evidence of the existence of metakaolin was obtained. On the basis of petrographic data it is possible to assume the presence of pseudomorphosis from kaolinite of the dehydrated residue; the Debye

graphs show the absence of a cryst. lattice at 600° and 800°. The formation of a cryst. modification of Al_2O_3 begins at 900–1000°. According to the Debye graph it is the γ-Al_2O_3. The presence of Fe oxides (10%) prevents this formation, but amorphous SiO_2 (10%) has no effect. Mullitization begins at 1200° (formation of sillimanite according to petrographic study); in the presence of 10% Fe_2O_3 mullitization begins at 1000°. Pologi kaolin fired to grog at 600° shows after a 2nd firing an exothermic reaction with the following maxima of positive thermal effects (at 930° + 1.58 cal.). Repeated firing lowers the effect of the exothermal reaction. Kaolin fired at 800° shows a positive thermal effect only at 1170° and 1200° (+0.68 cal.); samples of Pologi kaolin fired to 1000° and 1200° show no positive thermal effect. Kaolin samples fired at 600° and afterward to 1000° and 1030° with 10% Fe_2O_3 show a positive thermal effect. Samples fired to 800°, 1000° and 1200° and then fired with 10% Fe_2O_3 addns. give no positive thermal effect. Kaolin samples fired at 600° and 1200° and then repeatedly fired with 10% SiO_2 addns. give no positive thermal effect; while those fired at 300° show positive thermal effect.
M. V. Condoide

Methods of determining slag resistance of refractories. P. P. Budnikov. *Trudy Kharkov. Khim.-Tekhnol. Inst. S. M. Kirova* **1**, 34–49(in English, 49–50)(1939).— To det. slag resistance of grog, magnesite and chrome-magnesite brick a hole, made in the sample brick, is filled with basic metallurgical slag. Two C electrodes are introduced into the hole. The slag resistance of different refractories was also detd. by measuring the fusing temps. of mixts. of refractory and slag, or with other chem. agents. Results are tabulated. M. V. Condoide

Fused porcelain. W. E. Herbert. *Brit. Dental J.* **66**, 321–37(1939); *Chem. Zentr.* **1939, II**, 925.—A review of the properties of fused porcelain and the technique of manuf. of porcelain fillings, crowns and teeth.

Glass-melting furnace. Paul G. Willetts (to Hartford-Empire Co.). Can. 386,048, Jan. 2, 1940. Structural and operative details are described for forming an insulated glass-furnace bottom by placing a layer of glass-resistant nonshrinking refractory blocks, having a glassy matrix phase separable by heat, upon a layer of granular material over a layer of insulating material, filling the spaces between the blacks by casting a slip contg. refractory grains capable of reacting with the glassy matrix phase, and heating the bottom to free a portion of the glassy matrix phase for reaction with the slip to form a monolithic structure. 1

Electric glass-melting furnace and operation. John H. Thomas (to Owens-Ill. Glass Co.). U. S. 2,181,030, Nov. 21. App. is described, and a method of melting glass which involves establishing a body of glass materials, passing an a. c. in a predetd. convoluted path embedded in the body and which borders on the periphery of an interior zone of the body of glass materials and thereby preheating the glass adjacent the path by means of heat generated by the ohmic resistance to the current within the path, and passing the preheated glass materials into the interior zone through the interstices of the path and causing the glass to be finally heated by the induced flow of elec. current from the a. c. in the path. 2 3

Furnace operation for glass production. Samuel A. Forter (to Forter-Teichmann Co.). U. S. 2,179,848, Nov. 14. In a reversing regenerator furnace that has a plurality of ports on each of the two sides of the furnace and a corresponding plurality of regenerator units, continuity of furnace operation is maintained by establishing flow from the auxiliary conveying means through one of the ports while the associate regenerator unit is withdrawn from service. App. is described. 4

Glass-skimming and -conditioning apparatus. Thomas F. Pearson (to Crown Cork & Seal Co.). U. S. 2,180,767, Nov. 21. App. for conditioning glass in a forehearth comprises a refractory bridge supported by the forehearth side walls and spaced rearwardly from the front wall of the forehearth and extending transversely thereof with its bottom surface above the forehearth floor to form a channel therebetween and with its upper surface below the normal level of glass within the forehearth, a skimmer and means for moving the skimmer through the glass from a vertical plane adjacent the bridge to a position rearwardly thereof to draw the upper surface of relatively cold glass from the space between the front wall and the bridge rearwardly over the bridge and to circulate hot glass forwardly under the bridge to the space. 5

Container for molten glass. Paul G. Willetts (to Hartford-Empire Co.). Can. 386,049, Jan. 2, 1940. Electrocast grains (about 85 parts) in graded sizes and contg. mullite crystals and siliceous glass capable of sepg. from the grains under heat are intimately mixed with about 15 parts of 100-mesh Al_2O_3, the mixt. is firmly compacted in the bottom of the container to expose it to contact with molten glass over at least a part of the area of the bottom, and the container is heated to cause the siliceous glass to react with the finely divided Al_2O_3 and produce addnl. mullite crystals and decrease the amt. of glass in the material. 6

Apparatus for manufacture of glassware such as bottles. Thomas F. Pearson (to Crown Cork & Seal Co.). U. S. 2,180,766, Nov. 21. Various structural, mech. and operative details. 7

Blowing and heat-treatment of glass articles such as bottles. Henry W. Hess. U. S. 2,180,737, Nov. 21. App. is described, and a method which involves blowing a hollow article from plastic glass, allowing the escape of blowing gas from the interior of the article during the shaping operation, controlling the speed and temp. of the blowing gas so as to cool the interior surface of the article approx. equally with the cooling of the exterior surface by its contact with the mold, thereafter removing the article from the mold as soon as it will retain its shape when suspended, suspending the removed article and cooling its entire surface substantially uniformly to below annealing temp. by applying blasts of moving gases to its entire surface. 8

Mirrors. The British Thomson-Houston Co. Ltd. Brit. 506,116, May 23, 1939. A backing for glass mirrors comprises a metallic reflecting layer of Ag with a reinforcing layer of Ag and a protective coating of Na silicate contg. a reducing agent that will absorb the O occluded in the backing. The reflecting layer may be chemically de- 9

posited, and the reinforcing layer electrolytically deposited, and the reducing agent may comprise comminuted graphite. The protective layer may be applied in 2 layers, the 1st comprising an aq. Na silicate soln. contg. Na_2O 13–14 and SiO_2 31–32% and the 2nd comprising Na silicate contg. comminuted graphite.

Deterioration-resistant reflector of silver, etc. John R. Cain. U. S. 2,179,491, Nov. 14. Over a foundation layer of pure Ag of a thickness of about 0.03 in. or more, having a reflecting surface, there is placed a thin transparent vitreous enamel coating fused on the reflecting surface and contg. oxides of Si and Pb as major constituents and oxides of Na and B as minor constituents and having a working range well under the m. p. of pure Ag.

Laminated glass. Frederic L. Bishop (to American Window Glass Co.). U. S. 2,180,625, Nov. 21. A method of manuf. involves heating a soln. comprising a strengthening material such as an acrylic acid ester and a solvent therefor, and heating a glass sheet, forming a layer of the heated strengthening material on the heated glass sheet, the materials being heated to a temp. sufficient to drive off a portion of the solvent or other liquid present, drying the layer of strengthening material, and then uniting the coated glass sheet with another similarly coated sheet with the layer of strengthening material between the glass sheets.

Safety glass [nonshattering and bulletproof]. Krétatermékgyár Kft. Hung. 122,726, Jan. 2, 1940. Glass sheets are cemented together at 100–200° with resinous material previously treated with rubber, oil, glycerol, benzene, gasoline, AcOEt or formic acid.

Apparatus for making clay products such as flat disks. Charles E. Doll and Claude F. Copeland. U. S. 2,180,895, Nov. 21. Various structural, mech. and operative details.

Green ceramic coloring material. Gustav Jaeger and Heinrich Diehl (to Deutsche Gold- und Silber-Scheideanstalt vorm. Roessler). U. S. 2,180,056, Nov. 14. A green coloring material, resistant to heating, is obtained by heating together, to about 1100–1500°, Be oxide or a Be compd. yielding the oxide on heating, and Cr oxide or a Cr compd. yielding the oxide on heating.

Lightweight fluid-pervious ceramic bodies suitable for heat insulation. Earnest T. Hermann. U. S. 2,180,757, Nov. 21. A method of mfg. a ceramic pervious body comprises shaving of agglomerate particles from a mass of plastic argillaceous material in such condition that the particles have no tendency to interbond plasticly on contact with each other, subjecting the particles to a heat-treatment at a temp. sufficient to cause each particle to develop an internal bond and produce significant firing shrinkage in the particles but insufficient to cause a bond between the particles, coating the fired particles with an aq. medium contg. an argillaceous bonding material so as to obtain plastic interbonding of the particles, forming the coated particles into a body having a high percentage of mutually intercommunicating voids and a multiplicity of internal surfaces defining the voids, and then causing the particles to interbond to form an integral body by heat-treatment thereof at a temp. in excess of the first-named temp.

Horizontal tunnel kiln for ceramic ware. Jules J. Durieux. U. S. 2,180,041, Nov. 14. Various structural and operative details.

Refractory units for lining furnaces such as rotary kilns. Gilbert E. Seil (to E. J. Lavino and Co.). U. S. 2,180,969, Nov. 21. Shaped blocks of material such as refractory bricks are provided with a cementatory adhering coating of material such as a refractory cement on a portion only of their faces.

Zirconia zircon-silicon refractory suitable for furnace linings, etc. John D. Morgan (to Power Patents Co.). U. S. 2,179,982, Nov. 14. A method of making a bonded refractory involves mixing about 16–66 parts of finely crushed (220-mesh) ZrO_2 with 2–8 parts of milled grain zircon, wetting the mixt. with water and about 6 parts of H_3PO_4 to a creamy consistency, reducing the mixt. to the consistency of a thick paste by digestion for several hrs. at about 93–175°, adding water to increase the fluidity of the mixt. and thoroughly mixing with it about 76–20 parts of coarsely ground ferrosilicon (10–60-mesh), digesting the mixt. while agitating it and while heat-drying it to a suitable consistency for casting, and shaping, drying and hardening the product.

Abrasive article. Samuel S. Kistler (to Norton Co.). Can. 386,354, Jan. 16, 1940. To a phenol-formaldehyde condensation product is added an agent capable of absorbing water liberated when the material is heated to polymerize it, abrasive grains are added, and the mixt. is molded into desired shape and heated. The dehydrating agent prevents swelling.

Abrasive-coated articles such as paper. Raymond C. Benner and Norman P. Robie (to Carborundum Co.). U. S. 2,179,487, Nov. 14. Abrasive grains are secured to a backing such as paper by a heat-hardened bond consisting mainly of the reaction product of lignin, a phenol, and an aldehyde and suitably contg. not more than 40% lignin.

20—CEMENT AND OTHER BUILDING MATERIALS

J. C. WITT

How many specifications for cement? Report of special subcommittee of American Society Testing Materials Committee C-1 on cement. F. H. Jackson, *et al.* *ASTM Bull.* No. **102**, 39–42(1940).—Specifications are proposed. G. G.

The quaternary system CaO–Al_2O_3–$CaSO_4$–H_2O at 25°. F. E. Jones. *Trans. Faraday Soc.* **35**, 1484–510(1939). —That portion of the system of particular interest in cement chemistry has been worked out, i. e., the Ca sulfoaluminates arising during the setting of portland cement and by the action of sulfate waters on concrete. A space model was constructed including cryst. $Ca(OH)_2$ and the gel form of hydrated Al_2O_3 as solid phases. Only the high-sulfate form of Ca sulfoaluminate occurs [$(CaO)_3$.-Al_2O_3.$3CaSO_4$.$32H_2O$] which turns out to be sol. in H_2O and in dil. solns. of both lime and $CaSO_4$. Above a certain concn. of $CaSO_4$ it is stable but in lime solns. it is sol. only within a limited range of concns. Victor R. Deitz

The hydration of magnesian lime and the autoclave test. F. C. Welch. *Am. Soc. Testing Materials, Symposium on Lime* **1939**, 20–31(1940).—Bricks were bonded with mortars made in various ways, including some with lime autoclaved at 8 atm. to ensure full hydration of MgO, and the specimens were kept under different conditions and examd. at intervals. Pats of plaster for base and finish coats were prepd. with limes varying in MgO content, some previously autoclaved, and after different periods of aging in the lab. were autoclaved with the same procedure as used in testing limes. No relation between behavior on autoclaving of mortar and plaster contg. unhydrated MgO and under conditions of practical service was noted. It is concluded that continued hydration of MgO in mortar joints or plaster coats has no harmful effects. In small-scale tests, lime putties were prepd. from dolomitic lime; the results indicated that under conditions favorable to retention of the heat of hydration, MgO is almost completely hydrated overnight.
C. J. Schollenberger

The effect of the addition of finely ground inert materials to concrete. Robert Chapman and P. E. Olsen. *J. Inst. Engrs. Australia* **11**, 383–8(1939); cf. *C. A.* **34**, 6053.—A discussion. George Ayers

Variations in properties of dolomitic-lime putties with method of hydration. John E. Conley. *Am. Soc. Testing Materials, Symposium on Lime* **1939**, 7–19(1940). —Dolomitic limestones were calcined and hydrated under

controlled conditions in lab. expts. and vol., plasticity and settling rate of the putties studied. Putty properties depend upon type and characteristics of the original limestone, modified by treatment in calcination and hydration. Plasticity of putties from both dry and moist hydrates increased with temp. of hydration to an optimum at approx. 90°. Hydration with H_2O in excess of theory increased plasticity and vol. Electrolytes including Na_2SiO_3, NaCl, Na_2SO_4, NaOH, Na_2CO_3 and $NaHCO_3$ generally decreased plasticity with these dolomitic hydrates; effects upon putty vol. and rate of hydration varied. $CaCl_2$ and $MgCl_2$ affected plasticity little, but increased rate of hydration and decreased vol. AcOH improved the plasticity and increased rate of hydration and vol. Control of calcination to produce an active MgO and temp. control to ensure complete hydration of MgO are desirable in making hydrate for finishing plaster. Settling rates varied with conditions in calcination and hydration and are not abs. measures of plasticity; with hydration in the range 35–107°, settling rates varied inversely with temp. With highly plastic hydrate putties the settling rate is usually slow, but the properties are not necessarily assocd.; hydrates that yield high putty vols. are generally slow settling. Sixteen references.
C. J. Schollenberger

γ-Ray analysis of concrete containing iron. P. A. Shaikevich. *J. Tech. Phys.* (U. S. S. R.) **9**, 1478–83 (1939).—The analysis enables the observer to detect deformation of metal parts included in concrete, of holes in it, etc. J. J. Bikerman

Lime characteristics and their effect on construction. Walter C. Voss. *Am. Soc. Testing Materials, Symposium on Lime* **1939**, 103–16(1940).—Some connections between chem. compn. considered in ASTM specifications for builder's lime and such practical factors as putty yields, vol. changes and workability of mortars and the use of lime in concrete are discussed. The wt. of lime solids in 1 cu. ft. of putty, at any given time after slaking, equals 1.7 times the difference between the wt. of 1 cu. ft. of the putty at that time and 62 lb. Forty-five lb. lime solids is a rational av. value for 1 cu. ft. putty. Apparent yields of putties are misleading and tend to oversanding; they should be on the lime solids basis. Waterproofed limes produce light-wt. putty in fictitious yield. Cement mortars stabilize slowly and expand more, but at a lower rate, than high-lime mortars. Mortars made with dolomitic hydrate shrink more than those with high Ca hydrate; the latter show lower expansion after many cycles and stabilize rapidly, but have the most rapid initial expansion on wetting; they increase in wt. but decrease in vol. on seasoning from carbonation and increased density. The initial permeability of concrete can be reduced 50% by replacing 10% of the cement by lime solids, and this is structurally safe practice. C. J. Schollenberger

The preservation of wood. G. Batta. *Ind. chim. belge* **10**, 395–403(1939).—A review. E. H.

Bakelited wood and its physical and chemical properties. E. N. Rassadina. *Lesokhim. Prom.* **1938**, No. 3–4, 24–8; *Khim. Referat. Zhur.* **2**, No. 4, 130(1939); cf. *C. A.* **34**, 1095⁴.—The even distribution of bakelite in wood and its presence not only in the large pores of wood but also in cells and walls of the phloem are the main requirements for the production of nonswelling wood. Five to 10% solns. of bakelite penetrate the phloem, leaving bakelite distributed unevenly between bubbles of air and liquid. Swelling of birch wood compressed 25% after satn. was a min. when 5–10% solns. of bakelite were used. Water absorption decreased with an increase of the bakelite content. The introduction of not less than 20% of resin for the reduction of swelling is necessary if the wood is not compressed after satn. Optimum results are obtained from the satn. with resinite instead of with alc. solns. of bakelite. The following mech. properties were detd.: vol. wt. 0.87, compression strength 1460 kg./sq. cm., static bending strength 2060 kg./sq. cm., absorption of water after 12 days 10% (30% with a chopped sample) and swelling in tangential direction 3% (against 7.5% for natural wood). W. R. Henn

Fire resistance. The comparative resistance to fire of various species of timber. J. Bryan and L. S. Doman. *Wood* **5**, 19–23(1940).—Lab. tests on many types of wood were made to det. (1) the resistance to ignition from relatively small heat sources, (2) resistance to the penetration from a large heat source as would obtain in an established fire, and (3) rate of spread of burning or rate of heat evolution. In the app. for testing the rate of burning the specimen ($50^1/_2$-in. cubes) is burnt in the combustion tube, which being suspended from a balance arm, enables the loss of wt. to be measured. In the inflammability test the flame from the burner ignites the face of the lower specimen ($^1/_2$ in. thick, 5 in. square) and the time taken for this in turn to ignite the specimen (5 in. square, $^1/_2$ in. thick, $^1/_8$ in. away) opposite is recorded. In the flame penetration test the specimen (5 in. square, $^1/_2$ in. thick) rotates above the blow pipe, so that the flame describes a circle one in. in diam. The app. used are described and shown. More than eighty kinds of wood are classified according to fire resistance. L. S.

Stucco cement composition. Vito Morgero. U. S. 2,179,754, Nov. 14. A coating for the exterior of buildings is formed of sand, plaster such as rock wall or gypsum plaster, portland cement and milk, the sand being at least twice the wt. of the portland cement and the plaster being of no greater wt. than the portland cement.

Bituminous nonskid pavement. Joseph H. Conzelman (to Alabama Asphaltic Limestone Co.). U. S. 2,180,339, Nov. 21. A pavement is formed comprising a compacted layer of bituminous mixt. having a lower portion contg. a well balanced dense aggregate, the particles of which are coated and bonded together with bitumen to form a stable water-sealing strata and an upper portion contg. an unbalanced relatively open aggregate the particles of which are coated and bonded together with bitumen to provide a nonskid tractive surface, the upper portion forming a substantial part of the layer and merging into and being integral with the lower portion.

Improvement of bituminous road materials. Pétrole et Matieres Premieres. Fr. 840,925, May 8, 1939. In the bituminous matter is incorporated 0.5–20% of an insol. metallic soap dissolved in a carboxylic acid of a high mol. wt., with or without such a metallic salt as chloride, sulfate or nitrate. The insol. soap is preferably an Al soap; the oleate is the most recommended. As a solvent, oleic acid is preferred. The metallic salt is preferably a sulfate of Al, Fe, Cr or Mn.

Composite polychlorophenol product suitable for preserving wood, etc. Kent R. Fox, Edmund C. Hyry and Ira Hatfield (to Monsanto Chemical Co.). U. S. 2,180,142, Nov. 14. A solid homogeneous fused mass having a conchoidal or vitreous fracture, that is sol. in petroleum solvents of the fuel oil boiling range, consists essentially of a polychlorophenol such as tetra- or penta-

chlorophenol, which normally tends to bloom when applied as a soln. to wood, and a resin such as rosin or ester gum compatible with the polychlorophenol and sol. in such petroleum solvents in a proportion sufficient to prevent substantial blooming when the compn. is applied as a soln. to protect wood from decay organisms and fungi.

21—FUELS, GAS, TAR AND COKE

A. C. FIELDNER AND A. GEORGE STERN

Fuel specifications for injection engines. J. J. Broeze. *IIme Congr. mondiale pétrole* **3**, Sect. 4, 672–84(1937)(in French).—In a crit. study of Diesel fuel specifications it is stated that only those specifications are of value which give a direct indication of engine performance, e. g., viscosity, C residue, and ignition quality. The importance of viscosity in relation to proper starting and atomization has declined with advance in engine design. The relationship between ignition quality and C deposition is demonstrated by means of diagrams of the combustion chamber showing the typical C deposit with different ignition delay times. The Conradson C test is claimed to be a sufficient indication of the carbonizing tendency of the fuel until a better test can be devised. An attempt has been made to correlate the different Diesel fuel indexes with the cetane no. by means of charts. Closest agreement was found with the Diesel index proposed by Becker and Fischer (*C. A.* **29**, 316[9]). Results of Sunbury and Delft starting tests with 18 straight and doped fuels in various engines under different conditions are tabulated. E. J. Mahler

Use of heavy fuels in injection motors. J. J. Broeze. *IIme Congr. mondiale pétrole* **3**, Sect. 4, 685–95(1937)(in French).—Heavy low-grade oils can be burned cheaply in Diesels provided the engine is adjusted for their use. Problems presented by the high viscosity and low ignition quality of the fuel can be overcome by special injection design and by preheating. Carbon formation which is a real problem can be removed by the use of high wall temps. and by utilizing the scrubbing action of the hot flame gases which points the way for the adoption of two stroke or four-stroke engine of the turbulent chamber type; this necessitates the use of heat-resistant materials. Fuel injection temps. should be around 50–60°. Fuel consumption curves are given together with lubricating-oil contamination figures. A 0.2–0.4 mm. lining of chromium on the cylinder wall prevents excessive wear. E. J. Mahler

Causes of corrosive deposits in motors using "heavy fuel" (gasoline-alcohol mixtures). L. Boisselet and J. Fric. *IIme Congr. mondiale pétrole* **3**, Sect. 4, 708–11 (1937)(in French).—Corrosive deposits were observed in carburetors, gasoline lines and vessels contg. the French "heavy gasoline" composed of 65–75% heavy gasoline and 25–35% of abs. alc. denatured with various substances. Tests were carried out to det. the effect of each component of the mixt. on various metals. The deposits were traceable to the dye used in the fuel, viz., rhodamine B, and to the denaturant employed in the alc. E. J. Mahler

Diesel-fuel specifications: present and future. W. H. Hubner, Gustav Egloff and G. B. Murphy. *IIme Congr. mondiale pétrole* **3**, Sect. 4, 646–71(1937)(in English).—A survey was made of Diesel-fuel specifications supplementing a previous similar survey made 2 yrs. before (cf. *C. A.* **29**, 7609[9]). The following requirements are discussed: ignition quality, viscosity, cleanliness, distn. characteristics, Conradson carbon, ash, S and corrosive acids, flash point, pour point, gravity, gum, etc. Incorporated in the survey are the proposed A. S. T. M. fuel specifications for high, medium and low-speed Diesels, U. S. Army and Navy specifications for aircraft and submarine Diesel fuels, the recommended fuel specifications for eight railroads operating Diesel trains, and lastly the fuel specifications advanced by 53 Diesel-engine manufacturers throughout the world. Graphs are given showing the relationship between cetane no. and the various calcd. ignition quality expressions, e. g., Diesel index, viscosity-gravity const. b. p.-gravity const., U. O. P. number, and octane blending value. The effect of solvent extn. and of Diesel dopes on ignition quality is indicated. Particular attention is given to the effectiveness of ethyl nitrate in various fuels under various conditions. Its low b. p., 193°, is claimed to be a disadvantage. Other Diesel dopes are listed. Fuller cooperation between engine manufacturers and fuel producers is urged. E. J. Mahler

The development and present position of carbonization in a gas current. A. Thau. *Z. Ver. deut. Ing.* **83**, 1277–82(1939). E. H.

The coal resources of McCone County, Montana. A. J. Collier and M. M. Knechtel. *U. S. Geol. Survey, Bull.* 905, 80 pp.(1939). E. H.

Investigation of water in coal. Hatiro Kodama. *J. Chem. Soc. Japan* **60**, 861–74(1939).—It is suggested that water exists in coal in a dissolved state, and varies directly with the relative humidity. The satn. values are given for Manchurian coals. Since chem. reaction takes place in the coals above 50°, coal should not be heated at 105–10° in the detn. of water content. T. Katsurai

Determination of the quantitative relationships between the volatile and the humic constituents of coal by the salt-flotation method, and the adoption of a new classification of coals. P. D. Lysenko. *Coke and Chem.* (U. S. S. R.) **1938**, No. 11, 4–14; *Khim. Referat. Zhur.* **2**, No. 4, 111(1939); cf. *C. A.* **33**, 3997[2].—About 60–70% of gas coals can be used in the coking mixt A mixt. contg. moisture 3.8, ash 7.31, S 1.96 and volatile substances 30.6% yielded gas 347 cu. m. per ton, anhyd. tar 4.35% (sp. gr. 1.13), metallurgical coke 94.5%, shaft coke 74.1%, NH_3 0.364% and C_6H_6 1.56%. The coke contained moisture 1.22, ash 9.87, volatile substances 0.98 and S 1.64%. Cast iron made with this coke was of better quality and required 14% less coke. W. R. H.

Atmospheric oxidation of coal at moderate temperatures. Rates of the oxidation reaction for representative coking coals. L. D. Schmidt and J. L. Elder. *Ind. Eng. Chem.* **32**, 249–56(1940).—Rates of oxidation of samples representative of 8 coal beds were measured at temps. below 100°. The characteristic rates of oxidation of the coals increased with increasing volatile matter content. A coal of 38% volatile matter oxidized 3 times faster than a coal of 18% volatile matter (dry basis). The rate of oxidation of each fresh coal decreased rapidly as the coal consumed O, the rate being inversely proportional to the $1/4$ root of the amt. of O consumed. For all coals tested, the rate of oxidation was proportional to the 0.61 power of the O concn. in the gas phase. The rate of oxidation of coal from the Pittsburgh bed increased by a factor of about 1.7 for each 10° rise in temp. In general, the relative storing qualities of coals depend upon their friabilities as well as their characteristic rates of oxidation. For the coals tested, higher rates of oxidation tended to be compensated by lower friabilities. Joseph H. Wells

Ignition of coal and high-speed gasification. D. A. Frank-Kamenetskiĭ. *J. Tech. Phys.* (U. S. S. R.) **9**, 1457–64(1939).—Theoretical. Reactions between gas and solid are considered and the conditions stated for the rate of reaction detd. by the reaction const. and for it detd. by the rate of the gas flow. When the reaction is exothermic and the gas flow rapid the transition from one state to the other takes place suddenly at a definite temp. This explains the results of Grodzovskiĭ and Chukhanov (cf. *C. A.* **30**, 6163[7]). J. J. Bikerman

A new formula for the calculation of the fuel value of coals from analytical data. László Sümegi. *Magyar Mérnök Építészegylet Közlönye* **74**, 15(1940).—The formula of the former paper (*C. A.* **34**, 1459[8]) contains no values corresponding to the amount of heat produced by the oxidation of CO groups. Practical expts. proved that

the formula gives good results; hence this factor may be neglected. S. S. de Finály

Modern problems in internal-combustion engineering. W. J. Walker. *Trans. S. African Inst. Elec. Engrs.* 30, 116(1939).—A new theory for the detonation of fuels proposes that nuclear points of combustion act in the same manner as elec. emission devices which energize the air and form ozonides of explosive properties. The latter lead to secondary combustion. Colloidal Lead stabilized with 0.25% rubber gave pronounced anti-knocking properties. Detonation problems in gas, oil, Diesel engines and turbines are covered. George Papps

Purification of wood generator gas from tar by mechanical methods. V. Gundobin and B. Ladyshkin. *Lesokhim. Prom.* **1938**, No. 5, 5-8; *Khim. Referat. Zhur.* 2, No. 4, 131(1939).—In scrubbers best results were obtained in the 4-plate scrubbers with a const. circulation of tar at 50°. The coeff. of absorption in percentage of the initial content of tar in the gas was 82.4% for tar and 76% for AcOH. A sepn. of 96.3% of tar was obtained in Thiessen's app. W. R. Henn

Calorimetric determination of heat losses from small amounts of unburned flue gas. Wilhelm Bühne. *Brennstoff- u. Wärmewirt.* 21, 202-5(1939).—See *C. A.* 33, 8381[3]. J. E. D.

Burning low-volatile solid fuels. Lawrence W. Corbett (33% to Ralph N. Doble and 34% to Wm. H. Doble). U. S. 2,180,196, Nov. 14. App. is described, and a method of burning low-volatile solid fuel in domestic heaters substantially completely without the use of a secondary air supply, involves feeding the fuel by gravity to the apex of a conical fuel bed in such a manner as to establish and maintain a thin fuel bed, producing a gentle undulating motion in the fuel bed sufficient to prevent agglomeration without effecting substantial interchanges of green and hot fuel lumps, supplying air under pressure to the under side of the fuel bed through a resistance whereby the distribution of air supply is rendered substantially independent of the character of the bed, and removing the ash from the edges of the conical fuel bed.

Thermostatic and electric system for controlling the combustion of fuels such as oil. Willis H. Gille (to Minneapolis-Honeywell Regulator Co.). U. S. 2,180,675, Nov. 21. Various details.

Combustion apparatus of the vaporizing pot type. Ben Valjean (to Motor Wheel Corp.). U. S. 2,180,443-4, Nov. 21. Various details of app. suitable for the combustion of fuel oil.

Apparatus for analyzing gases such as exhaust gases from internal-combustion engines. Philip T. Sprague and Charles A. Sprague. U. S. 2,180,322, Nov. 14. Various structural and operative details of an app. suitable for use with absorbing agents for various constituents of the gas.

Treating natural gas. Bernard M. Laulhere (to Fluor Corp., Ltd.). U. S. 2,180,596, Nov. 21. Natural gas contg. hydrate-forming compds. is passed, under high pressure and at a temp. above that of hydrate formation at such pressure, through a cooling zone in which the gas is cooled to a temp. below the temp. of hydrate formation in the presence of water introduced to the gas stream in sufficient quantity to prevent clogging accumulations of pptd. hydrates in the cooling zone at their temp. of formation. App. is described.

Evaporative apparatus for odorizing natural gas with materials such as "calodorant." Wm. A. Green and Edward Rolle (to Standard Oil Co. of Calif.). U. S. 2,180,584, Nov. 21. Various structural and operative details for treating natural gas with an odorizing material as it flows through a tube or pipe line.

Retort closure and spraying device suitable for use in producing and carbureting gas. Paul W. Thayer. U. S. 2,180,565, Nov. 21. Various structural, mech. and operative details.

Gas producer. Heinrich Koppers (to Koppers Co.). U. S. 2,179,638, Nov. 14. Various structural and operative details.

Gas producer with a revolving grate. Heinrich Koppers (to Koppers Co.). U. S. 2,179,637, Nov. 14. Various structural and operative details.

Intermittently operated water-gas generator. Paul van Ackeren (to Koppers Co.). U. S. 2,179,650, Nov. 14. Various structural and operative details.

Controlling apparatus for the displaceable elements of water-gas manufacturing plants and other plants involving cyclical changes. Davison & Partner Ltd. and Marcus William Corss Smythson. Brit. 506,217, May 24, 1939.

Removing liquid tar and sludge from water gas. Charles H. Printz (to Gas Machinery Co.). U. S. 2,180,848-9, Nov. 21. Two communicating containers for wash water are provided, one above the other. Gas is continuously passed into the upper portion of the upper container. Liquid tar and sludge settle through the wash water of the upper container and into the lower container. The communication between two containers is closed periodically and the settled and segregated liquid tar and sludge are drawn off. The wash water in this container is replenished, and the communication between the containers reopened, without interrupting the flow of the gas.

Sulfonate sludge recovery. Frank W. Corkery (to Pennsylvania Industrial Chemical Corp.). U. S. 2,180,728, Nov. 21. A method of recovering sulfonate sludge from still residue resultant from the treatment and distn. of light oil derived from the by-product coking of coal and contg. water-insol. sulfonates formed by acid purification and alk. neutralization in the light oil prior to distn. consists in pptg. sulfonates from the still residue by agitating the still residue with low-boiling aliphatic hydrocarbon, wetting the ppt. by agitating the mixt. with water before the pptd. sulfonates coagulate, effecting stratification of the mixt. and settling of the ppt. expedited by injection of live steam into the mixt. to form a water layer contg. the sulfonates and a hydrocarbon layer contg. the other still-residue ingredients in soln., sepg. the layer of still-residue soln. and the sulfonate-contg. water layer, and by drying recovering the sulfonates as a residual sludge.

Coke-oven battery. Singleton H. Kimmel (to Koppers Co.). U. S. 2,179,635, Nov. 14. Various structural and operative details.

Regenerative coke oven. Joseph Becker (to Koppers Co.). U. S. 2,180,857, Nov. 21. Various structural details.

Operating mechanism for coke-oven doors. Ragnar Berg and Robert W. Crist (to Koppers Co.). U. S. 2,179,608, Nov. 14. Various structural, mech. and operative details.

22—PETROLEUM, LUBRICANTS, ASPHALT AND WOOD PRODUCTS

W. F. FARAGHER AND STEWART S. KURTZ, JR.

Properties of crude petroleums from Peru. Alfonso Montero Muelle. *Informaciones mem. soc. ing. Perú* **40**, No. 1, 56–66; No. 2, 88–107; No. 3, 88–98(1939).—Data on Peruvian crude oils obtained by methods of the U. S. Bureau of Mines are compiled in such a way as to be comparable with data on foreign crude oils. K. R. 2

Determination of molecular weights (of petroleum fractions). Application of the Reid bomb. Hector A. Gonzalez and Gabriel Castañeda. *Bol. informaciones petroleras* (Buenos Aires) **16**, No. 180, 29–33(1939).—The mol. wts. of gasoline, illuminating oil, absorption oil, gas oil and crude petroleum were detd. from the vapor pressure of dil. solns. of the fractions in Et_2O in the Reid bomb. Katharine Reinau 3

The problem of salts in crude petroleum. Julio V. Canessa and Manuel F. Romero. *Bol. informaciones petroleras* (Buenos Aires) **16**, No. 178, 12–16(1939). Katharine Reinau

Industrial processes of desalting (of petroleum). Bernando Rikles and Jose Stowasser. *Bol. informaciones petroleras* (Buenos Aires) **16**, No. 178, 17–30(1939).—A general review, particularly of U. S. work, which also includes some results on Argentinian crude oils with various processes. Katharine Reinau 4

Selective refining of mineral oils by means of phenols extracted from primary tars. Jeanette Cornea-Mavrodi and Virgil Niculescu. *Bull. sect. sci. acad. roumaine* **20**, No. 1–3, 35–45(1938).—See *C. A.* **33**, 8418. J. E. D.

Refinery gas: A raw material of growing importance. Robert E. Wilson. *Chemistry & Industry* **1939**, 1095–1101; *Ind. Eng. Chem., News Ed.* **17**, 697–8(1939).— 5 Chemical Industry Medal address for 1939. It is predicted that exploitation of veritable chem. mines in oil refiners' backyards will in the next 20 years yield developments of an importance far exceeding the dramatic growth of this industry in its first 2 decades. Cracked gases amounting to 940,000,000 cu. ft. per day are available from oil-refinery operations. Their uses are: (1) direct utilization of compds. sepd. from refinery gas, (2) raw material for the chem. industry and (3) conversion into motor fuel and other products primarily useful within the petroleum industry. Increasing quantities of butane are being incorporated in motor fuel. Propane is an extraordinarily versatile precipitant in solvent extn. processes because its solvent properties change so rapidly over the convenient temp. range between its b. p. (−44°F.) and its crit. temp. (212°F.). One company is making commercially more than 100 synthetic chemicals starting 7 from C_2H_4, C_3H_6 and the butylenes. Approx. 600,000 gals. of polymer gasoline is being synthesized daily from olefin gases. Also there is present plant capacity in excess of 300,000 gals. per day for isolating relatively pure hydrocarbons and treating them with other hydrocarbons to produce aviation gasoline. D. F. Brown

Effect of supercharge on the comparative evaluation of the knock of fuels. M. M. Maslennikov and G. E. Bliznyukov. *Tekhnika Vozdushnogo Flota* **1939**, No. 11, 30–9.—The effect of supercharge on the comparative evaluation of the knock of motor fuels was studied with a Waukesha engine using Grozny aviation gasoline, Baku gasoline, Orsk gasoline, and Dubroval gasoline contg. ethyl fluid or c. p. benzene. The antiknock effect of the ethyl fluid was apparently not affected by supercharging. The greatest stability against knocking was shown by unsatd. compds., the naphthenes and aromatic compds. were about 9 equal but both were next to the unsatd. compds., while the paraffins knocked the worst. The octane number detd. by the C. F. R. method gives an indication of the value of the fuel for work under supercharge only when there is a small difference (up to 10%) in the content of paraffins and unsatd. compds. When the difference is large, fuels with the same antiknock properties under supercharging will have different octane numbers by the C. F. R. method. Such discrepancies may reach up to four octane units. B. Z. Kamich

Southern oil in 1939 worth $800,000,000 at the well. Victor H. Scales. *Mfrs. Record* **109**, No. 1, 37, 66(1940).—A survey of manuf. Leopold Scheflan

Fundamental mechanical aspects of boundary lubrication. H. Blok. *S. A. E. Journal* **46**, 54–68T(1940). H. A. Beatty

Switch oils with low carbon formation. K. A. Andrianov and A. K. Vardenburg. *Vestnik Elektroprom.* **1939**, No. 9, 23–5.—C formation in switch oils as a result of the elec. arcs. was reduced by as much as 50% after the oils were subjected to an addnl. refining with H_2SO_4. The C formation was not influenced by addns. of water or paraffin. C formation increased rapidly when Ni was substituted for Cu as the electrode metal. This is probably due to the catalytic dehydrogenation of the oil in the presence of the Ni at high temp. caused by the elec. arcs. B. Z. Kamich

Influence of paraffin upon the characteristics of bitumen. III. Vasile Th. Cerchez and Virgil Niculescu. *Atti X° congr. intern. chim.* **4**, 211–15(1939).—See *C. A.* **33**, 7543[1]. J. E. D.

Asphalts obtained from Argentinian petroleums. Alberto Zanetta. *Bol. informaciones petroleras* (Buenos Aires) **16**, No. 174, 3–11(1939).—Data on the Argentine product in comparison with asphalts from other countries and fields. Katharine Reinau

Naval store studies. C. F. Speh. *Mfrs. Record* **109**, No. 2, 30–1, 54(1940).—A historical review. L. S.

Destructive distillation of agricultural wastes. P. Burke Jacobs. *Ind. Eng. Chem.* **32**, 214–26(1940).—The history and development of the continuous destructive distn. process as applied to wheat straw, cornstalks, oat hulls, rice hulls, and sawdust is described. Product compn. and yields are given, and uses of the products are discussed. H. G. Bowlus

Recent advances in chem. utilization of wood in United 6 States [wood distn. products] (Benson) **23**. Modern problems in internal-combustion engineering (Walker) **21**. Purification of wood generator gas from tar by mech. methods (Gundobin, Ladyshkin) **21** Isomerization of olefins (Fr. pat. 841,004) **10**.

The Cracking Art in 1938. Edited by **Gustav Egloff.** Chicago: Universal Oil Products Co. Research Labs. 458 pp.

Fractional distillation of petroleum oils and solvents, etc. Merrell R. Fenske (to Pennsylvania Research Corp.). U. S. 2,180,512, Nov. 21. Various details of app. and operation which may be controlled with use of a colorimeter and photoelec. cell, etc. 8

Distillation and cracking of petroleum oil hydrocarbons. Geo. Armistead, Jr. (to Gasoline Products Co.). U. S. 2,179,989, Nov. 14. Crude petroleum is distd. to form a crude residuum, a gas-oil condensate and a naphtha condensate. The naphtha condensate is passed to an elongated cracking zone of restricted cross section. The crude residuum is introduced into the same cracking zone intermediately between the ends thereof into admixture with the cracked naphtha, and the admixed hydrocarbons are passed through the remainder of the cracking zone. The cracked products are sepd. into vapors and residue, the vapors sepd. into a heavy gas oil condensate and a desired distillate, the gas-oil condensate from the crude

distn. is introduced into a second elongated cracking zone of restricted cross section, the aforesaid heavy gas-oil condensate is introduced into the second cracking zone intermediately between the ends thereof and into admixture with the condensate therein. The products from the second cracking zone are fractionated to recover desired products.

Gas lift or natural flow oil well. Howard C. Pyle (to Union Oil Co. of Calif.). U. S. 2,181,099, Nov. 21. Means for reducing the bottom-hole back-pressure required for a given rate of production in a naturally flowing or gas-lift well comprises a well contg. tubing and casing and means supported by the tubing near the bottom of the casing substantially to seal the annular spacing therebetween and means to maintain a reduced gas pressure in the annular space between the tubing and the casing above the sealing means.

Solidifying or sealing off formations traversed by a well. Franklin A. Bent and Albert G. Loomis (to Shell Development Co.). Can. 386,195, Jan. 9, 1940. A nonaq. drilling fluid comprising an org. compd. of Si dispersed in a nonaq. solvent selected from the group consisting of mineral oil, gasoline, naphtha, benzene, alcs., esters and ketones is introduced under pressure, and the insol. ppt. deposited on the walls of the borehole and within the adjacent formations. An app. is described.

Sealing water-bearing strata. Hijman Limburg (to Shell Development Co.). Can. 386,200, Jan. 9, 1940. A soln. of asphalt bitumen in an org. solvent, e. g., pyridine, adapted to ppt. asphalt when dild. with water, is introduced into water-bearing strata.

Separator suitable for treating emulsified water and oil from wells. Henry V. King. U. S. 2,180,811, Nov. 21. Various structural and operative details.

Fractionating hydrocarbon oils such as Venezuelan distillate oils. Gerritt W. Nederbragt (to Shell Development Co.). U. S. 2,180,763, Nov. 21; Can. 386,199, Jan. 9, 1940. A process for producing a normally liquid, essentially nonaromatic hydrocarbon product involves dewaxing a wax-bearing hydrocarbon mixt. in the presence of a selective solvent for aromatic hydrocarbons to produce a soln. of a substantially wax-free hydrocarbon mixt. in the solvent, removing the wax from the soln., cooling the soln. to a temp. between about −35° and −125° sufficiently low to solidify a portion of the hydrocarbons as a solid phase and form simultaneous liquid raffinate and extract phases, the solvent being capable of forming the two liquid phases at the low temp. and having a sufficient solvent power to dissolve all liquid hydrocarbons in a single liquid phase at a higher temp. at which at least a portion of the wax-free hydrocarbons are solidified, sepg. the solid phase from the liquid phases, sepg. the remaining liquid phases one from the other, combining hydrocarbons in the sepd. solid phase with hydrocarbons in the sepd. liquid raffinate phase and reliquefying the hydrocarbons in the solid phase to form a normally liquid, essentially nonaromatic product.

Refining hydrocarbon oils with mixed solvents. James W. Weir (to Edeleanu G. m. b. H.). U. S. 2,179,909, Nov. 14. For sepg. high viscosity index from low viscosity index components, an oil such as a dewaxed Calif. oil distillate is treated with a mixt. of a pyridine type solvent and an auxiliary selective solvent such as $PhNO_2$, aniline or chloraniline which does not react with alkali, in the presence of an alkali metal hydroxide soln. in sufficient amount to form 3 phases, the ext. phase being dispersed in a continuous raffinate phase, and the 3 phases are then sepd.

Removing gum-forming and color-imparting substances from cracked unsaturated hydrocarbon oils. Rudolph C. Osterstrom (to Pure Oil Co.). U. S. 2,180,324, Nov. 14. An arrangement of app. is described, and a process for effecting the removal of gum-forming and color-imparting compds. from cracked low-boiling unsatd. hydrocarbon oils, which involves passing a solely petroleum liquid mixt. of such oils and hydrocarbon polymers contg. the compds. through a heating zone, where the mixt. is heated in the liquid phase to a temp. of the order of 3:5° while maintained under pressures of the order of 1200 lb. per sq. in.

Treatment of a synthetic hydrocarbon oil. Hendrikus Stokman (to Shell Development Co.). Can. 386,196, Jan. 9, 1940. The oil produced by polymerization of olefins with an active halide polymerization catalyst is treated to decrease chemically bound halogen to not more than 0.002% by contact with a bleaching clay in amt. 2–4% by wt. of the oil at 200–300° for above 10 min. and insufficiently long to render the oil unstable.

Sweetening sour hydrocarbon distillates. Virden W. Wilson (to Buffalo Electro-Chemical Co.). U. S. 2,181,036, Nov. 21. A distillate such as a gasoline distillate is treated with an alc. soln. of caustic alkali and an oxidizing agent yielding H_2O_2. U. S. 2,181,037 describes an arrangement of app. and a method of sweetening sour distillates by treatment with a MeOH soln. of a caustic alkali and water and an oxidizing agent capable of liberating H_2O_2.

Separation of paraffins from nonparaffins in a hydrocarbon oil. Virgil Leland Hansley (to E. I. du Pont de Nemours & Co.). Can. 385,898, Dec. 26, 1939. The oil is extd. with a mixt. of *N,N*-dialkylformamide and $(ClCH_2CH_2)_2O$.

Liquid products from normally gaseous hydrocarbons. Mathias Pier (to I. G. Farbenind. A.-G.). U. S. 2,179,829, Nov. 14. App. is described, and a process which involves heating normally gaseous hydrocarbon material such as C_4H_{10} in a tubular space to above 500° to effect at least partial dehydrogenation and then subjecting the dehydrogenated material to polymerization by passing it through a space surrounding the tubular space mentioned and which is maintained at an elevated temp. at least about 20° lower than the tubular space.

Regenerating aluminum chloride catalysts used with hydrocarbon oils. Geo. A. Boyd (to Standard Oil Co. of Ind.). U. S. 2,180,220, Nov. 14. A catalyst complex formed by the reaction of an $AlCl_3$ catalyst with a hydrocarbon oil is broken down by treatment with CO and a promoter such as H, Cl or HCl at a temp. above room temp. but below 260° (suitably about 65–70°).

Absorbent clay suitable for treating oils, etc. Walter S. Baylis and Wm. Kelley (to Fullerite, Inc.). U. S. 2,180,576, Nov. 21. An arrangement of app. is described, and a process of producing a highly active acid-treated fuller's earth or clay which includes: mixing a quantity of unground hydrous Al silicate and a strong mineral acid with sufficient water to make a readily flowable pulp therefrom; heating the mixt. under pressure with substantially no agitation thereof, whereby the natural grain size of the silicate particles is preserved; washing the treated mixt. to remove free acid and sol. salts therefrom; and drying the washed silicate.

Extraction of naphthenic acid. Johannes H. W. R. van Tonningen (to Shell Development Co.). Can. 386,508, Jan. 23, 1940. A hydrocarbon oil, e. g., a kerosene distillate, contg. naphthenic acids boiling within the distn. range of the kerosene is treated with an aq. NH_3 soln. to form a hydrocarbon layer and an aq. layer contg. a larger portion of the carboxylic acids, and the layers sepd. An app. is described.

Stabilizing liquid hydrocarbon materials such as gasolines. Charles H. Fisher (to Pennsylvania Coal Products Co.). U. S. 2,176,883, Oct. 24. For inhibiting discoloration and gum formation during storage, the material is mixed with about 0.01% or less of a tetraalkylhexahydroxyspirobiindan.

Gasoline. Bernard H. Shoemaker (to Standard Oil Co. of Ind.). U. S. 2,180,372, Nov. 21. An arrangement of app. is described, and a process of producing high knock-rating gasoline from heavy hydrocarbon oil, which comprises heating the hydrocarbon oil charging stock to cracking temp. and converting about 25–40% thereof to gasoline, sepg. unvaporized heavy residue from the vapors of gasoline and unconverted heavy oil, cooling the vapors of gasoline and unconverted heavy oil and bringing them into contact with a catalytic mass of argillaceous earth at a temp. of about 370–425°, thereafter conducting the vapors

to a fractionating zone, therein sepg. gasoline from unconverted heavy oil and recycling the unconverted heavy oil, consisting of about 60–75% of the charging stock, to the cracking step.

Gasoline products. Eldon E. Stahly and Erwin M. Hattox (to Standard Oil Development Co.). U. S. 2,180,374, Nov. 21. An arrangement of app. is described, and a process suitable for the treatment of gaseous mixts. from oil cracking, etc., which involves treating a mixt. contg. at least one low-boiling isoparaffin with at least one member of the group consisting of normally gaseous mono-olefins, dimers, trimers, tetramers and higher polymers thereof, co-, inter-, and cross-dimers, trimers, tetramers and higher analogous polymers thereof, in the presence of a catalyst taken from the group consisting of a catalyst of the type QX.ZX wherein Q stands for a metal other than Al, Z stands for Al, the molar ratio of ZX to QX being greater than 1 to 1, and X is a halogen.

Fuel oil. Garland H. B. Davis (to Standard Oil Development Co.). Can. 386,368, Jan. 16, 1940. An improved fuel oil contains both waxy and asphaltic materials and a small amt. of an aliphatic or an aromatic amine and a hydroxylated deriv. of these.

Oil filter suitable for use with internal-combustion engines. Conrad E. Frudden (to Allis-Chalmers Mfg. Co.). U. S. 2,179,784, Nov. 14. Various structural details.

Petroleum lubricating oil mixtures. Arnold C. Vobach (to Sinclair Refining Co.). U. S. 2,180,697, Nov. 21. About 0.5–2.5% of a phenyl stearate of Al, Ba, Cd, Cr, Mg or Ni is mixed with a petroleum lubricating oil such as a Diesel-engine oil to improve stability and lessen sludge deposition. U. S. 2,180,698 relates to a mixt. of oil with about 0.5–2.5% of stannous phenyl stearate; and U. S. 2,180,699 relates to a mixt. of oil with about 0.5–2.5% of Zn phenyl stearate

Lubricating oils. Union Oil Company of California. Fr. 840,962, May 8, 1939. The introduction into lubricating oils of 0.8–3.0% of a metallic soap of a chlorinated acid contg. at least 14 C atoms increases the oiliness and prevents the formation of gummy deposits around the valves and segments of Diesel motors. A Ca soap is preferable. The chlorine content is about 20% of the acid, which corresponds to dichloro acids. Instead of a metallic soap of a chlorinated acid it is possible to use a mixt. of a metallic soap of a nonchlorinated acid together with a small amount of a compd. that will increase the oiliness and the pellicular resistance of the oils, such as the Me, Et and Am esters of halogenated fatty acids, the Me and Et esters of chlorinated synthetic petroleum acids, chlorinated naphthalene or sulfonated lard. Soaps of organic bases, such as triethanolamine, also can be used.

Lubricating oils suitable for use under high pressure and in metal cutting, etc. Bert H. Lincoln, Waldo L. Steiner and Alfred Henriksen (to Lubri-Zol Development Corp.). U. S. 2,180,008, Nov. 14. About 0.1% or more of a halogenated resorcinol such as chlorinated resorcinol is added to an oil such as S. A. E. 30 lubricant, and numerous similar mixts. are described.

Improvement of lubricating oils. Ruhrchemie A.-G. Fr. 840,980, May 8, 1939. See Brit. 490,930 (*C. A.* 33, 1139[1]).

Lubricating composition. George S. Cavanaugh (to Pennzoil Co.). Can. 386,360, Jan. 16, 1940. The sludge-dissolving property of mineral oil is increased by adding diethylene oxide, at least 0.05%, but in insufficient amt. materially to change the fire and flash characteristics of the oil.

Low-pour-test lubricating distillates. Herschel G. Smith (to Gulf Oil Corp.). U. S. 2,180,070, Nov. 14. In the manuf. of a high yield of low-cold-test lubricating distillates from low-grade crudes, a procedure is employed which involves reducing such a crude and recovering an uncracked pressable distillate and a residuum, distg. off from the residuum a heavy pressable distillate and a light overhead cylinder stock, mixing the pressable distillates and filter pressing the same to remove cryst., readily pressable wax; diluting the overhead cylinder stock, centrifuging the same for removal of wax, reducing the same to recover a lubricating distillate, uniting the lubricating distillate with the filter-pressed distillates, adding sufficient amorphous wax to render the wax content of the mixt. centrifugeable, removing the wax content by centrifuging in a liquid separator at low temps. and recovering a low-cold-test neutral oil.

Regeneration of used oils. László Hunyadi and Jenő Koch. Hung. 122,424, Dec. 15, 1939. Used oils are treated with clarifying substances, filtered and distd. A special app. effects automatic change of the direction of the oil in the filters.

Lubricants. Standard Oil Development Co. Brit. 508,335, June 29, 1939. A lubricant for extreme pressures or for cutting tools is made by causing a high-boiling org. compd. contg. an aliphatic chain to react with a sulfide, hydrosulfide or polysulfide of H, NH_3, alkali metal or alk.-earth metal. Preferably, an aliphatic hydrocarbon is caused to react with a polysulfide to give an org. polysulfide. Also, a chlorinated petroleum fraction may have all or part of its Cl replaced by S by treatment with 1 of the sulfides, hydrosulfides or polysulfides. A solid aliphatic hydrocarbon may be used in place of the petroleum fraction. An unsatd. hydrocarbon obtained by dehydrogenation or cracking of an aliphatic hydrocarbon, or a higher aliphatic alc., ketone or ester (preferably of 10 or more C atoms), may be caused to react with an inorg. polysulfide to produce an org. polysulfide.

Lubricant. Lawrence M. Henderson, William A. Whittier, Norman D. Williams and Harry L. Moir (to Pure Oil Co.). Can. 386,187, Jan. 9, 1940. A small amt. of S is made to react with a fatty substance, e. g., lard oil, a small amt. of P or a P compd. added, the mixt. heated to about 230°F. until the reaction is complete, and the product cooled.

Grease. Vernon L. Ricketts (to Shell Development Co.). Can. 386,507, Jan. 23, 1940. A grease contains a viscous mineral oil, a soda soap, and a minor proportion of Na salicylate.

Asphalt from petroleum residuum. Charles H. Whitacre (to Standard Oil Co. of Ohio). U. S. 2,179,988, Nov. 14. A mixt. of asphaltic residuum and cylinder stock is oxidized, and after discontinuing the oxidation the material is subjected to the action of about 0.1–1.0% of $AlCl_3$ at an elevated temp. not substantially higher than that of the oxidizing operation (suitably about 180°). Cf. *C. A.* 34, 1478[5].

'23—CELLULOSE AND PAPER

CARLETON E. CURRAN

Simplified method for the volumetric determination of α-cellulose. S. V. Goncharov and F. G. Burvasser. *Bumashnaya Prom.* 17, No. 10, 27–9(1939).—In a modification of the previous method (*C. A.* 31, 7639[9]) α-cellulose (I) is oxidized directly without preliminary soln. in 80% H_2SO_4 + AcOH. After the trituration of 0.3 g. of disintegrated sulfite pulp with 8 ml. of 17.5% KOH for 15 min., filter on a Büchner funnel, wash I with 10 ml. of *N* H_2SO_4, transfer it into a flask contg. 50 ml. H_2O, 50 g. of concd. H_2SO_4 and 2.5 g. $K_2Cr_2O_7$, boil 5 min. (exactly), cool, make up to 500 ml., withdraw 25 ml. of the soln. and titrate excess of $K_2Cr_2O_7$ with $Na_2S_2O_3$. Make a blank test. Chas. Blanc

The preparation of cellulose ethers. Thomas P. Clémens. *Rusta-Rayonne* 14, 431–5(1939).—A review of the chief Lilienfeld pats. (Brit. and Fr.). A. P.-C.

(Cellulose) plastics in ribbon form. Paul A. Koch. *Melliand-Textilber.* 20, 479–83(1940).—A review of vari-

ous products made from viscose or cellulose acetate by spinning through slits, by applying viscose to textile fabrics or by enclosing sheet material between 2 cellulose films, etc. Emphasis is placed on the possibilities of obtaining artistic effects, e. g., by printing, embossing or coloring such products, by plaiting strip material, etc. J. W. Perry

Lowering the viscosity of nitrocelluloses. Jules Michel. *Rev. gén. mat. plastiques* **15**, 282–5(1939).—A review and discussion of pats. on the lowering of the viscosity of nitrocellulose in acid and in alk. medium, and of the application of this lowering of viscosity to the prepn. of alc.-sol. nitrocelluloses. A. Papineau-Couture

Saccharification of wood. H. Schöller. *Chem.-Ztg.* **63**, 737–40, 752–4(1939); cf. *C. A.* **33**, 7543⁴.—A review. E. H.

The industrial hydrogenation of lignin. A. J. Bailey. *Pacific Chem. Met. Inds.* **4**, No. 1, 13–14, 16(1940).—A review with 34 references. E. H.

"Milky" viscose rayon. S. Poznanski. *Atti X° congr. intern. chim.* **4**, 804–11(1939).—See *C. A.* **33**, 5180². J. E. D.

Direct spinning of artificial fiber through the acetate method. I. Materials and the stability of the spinning solution. Risaburo Yosimura and Yosihiro Kisibata. *Repts. Osaka Imp. Ind. Research Lab.* **20**, No. 2, 100 pp. (1939).—This report describes in detail the materials, methods, and the factors affecting the stability of the spinning soln. F. I. Nakamura

Detection of toxic vapors in the rayon industry. Raoul Relaitre. *Rusta-Rayonne* **14**, 465, 467(1939).—A brief outline of tests for detecting H_2S ($Pb(OAc)_2$ paper), SO_2 (paper impregnated with starch, KI, KIO_3 and glycerol) and CS_2 (paper impregnated with Et_2NH and Cu acetate). A. Papineau-Couture

Recent advances in the chemical utilization of wood in the United States. H. K. Benson. *Atti X° congr. intern. chim.* **4**, 105–16(1939). —A discussion of wood as a source of paper pulp, cellulose derivs., staple fiber, naval stores, wood-distn. products, synthetic lumber and wood plastics. E. H.

Chemical composition of wood. II. V. I. Sharkov and F. A. Sartaniya. *Lesokhim. Prom.* **1938**, No. 3–4, 17–21; *Khim. Referat. Zhur.* **2**, No. 4, 130(1939); cf. *C. A.* **33**, 3584⁷.—On the basis of a generalization of previous data, conclusions are drawn as to the genesis of wood. W. R. Henn

Dispersion of wood material in a solution of zinc chloride. D. N. Lektorskiĭ. *Lesokhim. Prom.* **1938**, No. 5, 21; *Khim. Referat. Zhur.* **2**, No. 4, 129(1939).—The soly. of wood in solns. of KI, LiCl and $ZnCl_2$ of different concns. was investigated. Only solns. of $ZnCl_2$ dissolved the wood material. To prep. the soln. dissolve 150 g. of $ZnCl_2$ in 100 cc. of water contg. 0.15 g. of HCl, and treat 0.1–0.2 g. of the wood material with 100 cc. of the soln. for 5–15 min. at 135°. The product was shown to be a colloidal soln. by means of the Tindall app. and the ultramicroscope. The character of the process of soln. of the wood material depends on the acid used for dissolving $ZnCl_2$. On diln. with water the solns. decomp. with a sepn. of the wood material in the form of flakes. The color and the stability of the solns. point to a high degree of dispersion of the wood material in soln. W. R. Henn

Manchurian woods for manufacture of pulp. III. I. Miura. *Cellulose Ind.* (Tokyo) **15**, 4–6(1939); cf. *C. A.* **32**, 8134¹.—Pulps from Manchurian woods, the cooking properties of which had previously been studied (*loc. cit.*), were subjected to a two-stage bleaching process and the yield and properties of the resultant pulps detd. Of the woods examd., *Picea obovata*, Ledeb. (I), and *Abies nepherolepis*, Max. (II), are considered to be suitable raw materials for paper and rayon. They yield 41.4 and 37.5% (or 153 and 139 kg. per cu. m. of wood) of bleached pulp, having 89.5 and 91.8% of α-cellulose, resp. *Pinus koraiensis*, S. and Z. (III), and the hardwoods (two sorts of aspen, lime and birch) give bleached pulps which are inferior to I and II, although except for III their yields per cu. m. of wood are much greater than that of I and II. The aspens are easily digested by the sulfite process and give readily bleachable pulps. Max. yield per cu. m. of wood was obtained with *Betula mandshurica*, Nakai (41.4% or 298 kg. per cu. m. of wood), which has the highest vol.-wt., but the pulp from this wood has only 79.2% of α-cellulose. B. C. P. A.

Chemical composition of wood bark. V. Uronic acids in wood bark. V. I. Sharkov. *Lesokhim. Prom.* **1938**, No. 3–4, 16–17; *Khim. Referat. Zhur.* **2**, No. 4, 130 (1939); cf. *C. A.* **33**, 1050⁹.—Analytical data on the compn. of uronic acids in wood bark obtained by the methods of Nanji, Paton and Ling are: fir—bast 5.98–6.51%, bark 3.95–4.31%; birch—bast 7.35%, bark 2.20%; aspen—bark 3.56%. A part of the uronic acids which are contained in bark is not an integral part of pectins but is a part of the hemicellulose of the cell wall. A method was developed for the analysis of pectins, fruits, berries and fleshy roots. The method has not been verified for the analysis of wood material. W. R. Henn

Hydrolysis of peanut hulls. Frank C. Vilbrandt, C. B. Mather and R. S. Dicks. *Ind. Eng. Chem.* **32**, 169–72 (1940).—The action of water and of dil. sulfuric acid on peanut hulls at 20°, 50°, 80° and 100° with liquid-solid ratios of 10:1 and 8:1 was studied. Hydrolysis by water gave in 48 hrs. 5% of the dry wt. of the hulls as reducing sugars. Hydrolysis with 0.4 *N* H_2SO_4 gave in 48 hrs. 22% of reducing sugar. The amt. of reducing sugar increased with acid concn. up to 4.5 *N*; above 4.5 *N* and 80° the sugar decomposed. The rate of hydrolysis increased with temp., but little action occurred below 80°. The yield of sugar increased with time of treatment and approached a max. in about 48 hrs. H. G. Bowlus

Machines for chopping sawmill wood waste. G. S. Kovalevich. *Bumazhnaya Prom.* **17**, No. 10, 37–43 (1939).—From a comparison of the performance of the Karlstadt (Sweden) and Wieger (Germany) machines at the Solombal'skiĭ paper mill, the preference is given to the former installation. Chas. Blanc

The Swedish sulfate pulp industry. Erland Waldenström. *Wochbl. Papierfabr.* **70**, Tech. Tl. 943–4(1939).—A historical review. Louis E. Wise

Production of pulp by the nitric acid process. VIII. I. Simoda, N. Ebara, and T. Murakoski. *Cellulose Ind.* (Tokyo) **15**, 7–9(1939); cf. *C. A.* **33**, 8403¹.—Attempts were made to produce from straw HNO_3 pulp for rayon. Varying concns. of acid with and without admixture of H_2SO_4 were tried, and in each case digestion was carried out for 2 hrs. at 100° with a 2% aq. NaOH after-treatment at the same temp. for 1 hr. Complete digestion was obtained with 5% HNO_3, the pulp having 93.6% of α-cellulose (I). Max. I (95.6%) was reached with 9% HNO_3, but the ash content was never less than about 0.6% and is thus greater than that of com. sulfite pulps for the same purpose. In many respects, however, the HNO_3 straw pulp was superior to com. sulfite pulps, notably in I and pentosan content (min. 1.85%). With HNO_3–H_2SO_4 mixt. the I contents with 3–4% HNO_3 and 3% H_2SO_4 were similar to those with 7–8% HNO_3 alone, and pentosans were slightly reduced. It was not possible, however, to reduce the ash content of the pulp below the relatively unsatisfactory value of 0.6–0.8%. With 5% HNO_3 alone the pulp yield was about 31%, while with the mixed acids above it was reduced to about 28%. B. C. P. A.

Combined bleaching of pulp. F. P. Komarov. *Bumazhnaya Prom.* **17**, No. 10, 14–19(1939). F. P. Komarov and N. V. Lebedev. *Ibid.* No. 11, 16–20; cf. *C. A.* **34**, 884³.—In these 2 preliminary communications the literature is reviewed and the tentative lab. expts. are discussed. 30 references. Chas. Blanc

Rapid determination of (pulp) concentrations. D. N. Zhokhov. *Bumazhnaya Prom.* **17**, No. 10, 31–7(1939).—A discussion, with math. treatment, of the detn. of pulp in aq. suspension, based on the sepn. of pulp by centrifuging. Illustrations are given. Chas. Blanc

Causes of the contamination of Syask pulp with dirt. D. M. Shilinskiĭ. *Bumazhnaya Prom.* **17**, No. 10, 19–26 (1939).—A discussion with suggestions for improvement. Chas. Blanc

Preparation of strong and "superstrong" cooking acid. M. G. Eliashberg. *Bumazhnaya Prom.* **17**, No. 10, 8–14; No. 11, 6–13(1939). **Strong cooking acid for sulfite pulping.** K. V. Khodakov. *Ibid.* 14–15.—A discussion of the methods and installations for the production and recovery of strong SO_2 solns. and their uses in sulfite pulping, based chiefly on foreign practice. Chas. Blanc

The use of refining waste pulp mass in the purification of waste waters. A. I. Samyshkina. *Bumazhnaya Prom.* **17**, No. 10, 43–4(1939).—A complete decolorization and a reduction of 35% of org. matter in paper-mill waste waters can be effected by the addn. of refining waste mass in the process of filtration. Chas. Blanc

Determination of oxidizable matter in alkaline waste waters. L. Kh. Khristiansen and O. A. Kalendarova. *Bumazhnaya Prom.* **17**, No. 10, 55–7(1939). It is claimed that a greater accuracy can be attained in the detn. of org. matter in waste waters of sulfite and sulfate pulping by oxidation with $KMnO_4$ in alk. medium and avoiding boiling temp. Dil. waste water or strong waste liquor to a content of 0.15–0.25 g. of org. matter in 1000 ml. To 25 ml. of the soln. add 25 ml. of 0.1 *N* $KMnO_4$ and 10 ml. of 5% NaOH, immerse the flask in a boiling water bath and digest 40 min. Introduce 10 ml. of 25% H_2SO_4, let stand 10–15 min. and titrate back the excess of $KMnO_4$ with standard soln. of oxalic acid. Chas. Blanc

Purification of smoke gases and recovery of escaping chemicals in soda-regenerating installations of sulfate-pulp mills. S. M. Vishnevskiĭ. *Bumazhnaya Prom.* **17**, No. 11, 20–8(1939).—A review of Soviet and foreign practices, with literature references and illustrations. Chas. Blanc

Mangrove woods from Tanganyika for papermaking. Anon. *Bull. Imp. Inst.* **37**, 331–44(1939).—"Makandaa" wood (*Ceriops candolleana* Arn.) had the following compn. on the dry basis (H_2O 7.7%): resins (alc.-C_6H_6 ext.) 9.5, alkali soly. (via Schorger) 25.6, cellulose 49.1, ash 1.1%, fiber length 0.7–1.6 mm. (av. 1.4 mm.), fiber diam. 0.011–0.033 mm. (av. 0.021 mm.). Cooking 5 hrs. to a max. temp. of 160° with 4% NaOH soln. (20 parts NaOH per 100 parts oven-dry wood) yielded 38.9% of slightly undercooked, somewhat shivy pulp, which could not be bleached satisfactorily with 40% (on the dry wt. of the pulp) of standard bleaching powder, and which produced a slight shivy, dark-brown, hand-made sheet of very weak, soft paper. Cooking under more drastic conditions gave a considerably lower yield (32.8–33.9%) of pulp which could be bleached to a cream color with 30% of standard bleaching powder. "Mchuu" wood (*Avicennia officinalis*) showing considerable staining had the following compn. on the dry basis (H_2O 8.0%): resins (alc.-C_6H_6 ext.) 1.5, alkali soly. (via Schorger) 16.7, cellulose 54.7, ash 2.3%, fiber length 0.4–1.3 mm. (av. 1.0 mm.), fiber diam. 0.011–0.030 mm. (av. 0.020 mm.). Cooking 5 hrs. to a max. temp. of 160° with 4% NaOH soln. (24 parts NaOH per 100 parts oven-dry wood) yielded 42.1% of well-cooked pulp, free from shives which could not be fully bleached with 40% of standard bleaching powder and which produced a dark-brown, well-formed hand-made sheet of very weak, soft paper, free from shives but contg. numerous small brown specks. Two-stage bleaching with a total of 20% of standard bleaching powder produced a pulp of excellent whiteness, but with a shrinkage of over 10% (yield 32.3% on dry wood). "Makaka" wood (*Rhizophora mucronata*) had the following compn. on the dry basis (H_2O 7.6%): resins 4.4, cellulose 63.4, ash 1.5%, fiber length 0.8–2.1 mm. (av. 1.5 mm.), fiber diam. 0.016–0.043 mm. (av. 0.026 mm.). Cooking under the same conditions as for "mchuu" yielded 47.5% of well-cooked pulp completely free from shives, which could not be bleached with a reasonable quantity of bleaching powder, and which produced a dark-brown, well-formed hand sheet of very weak and soft paper, of loose spongy texture and free from shive. Cooking under more drastic conditions considerably reduced the yield (39.6–44.7%) without a corresponding improvement in the bleachability of the pulp. A. Papineau-Couture

Air requirements in paper manufacture. A. B. Davies. *Wochbl. Papierfabr.* **70**, Tech. Tl. 796–7(1939); cf. *Ind. Heating Engr.* **1**, No. 2, 42(1939).—For every ton of paper made from wood, rag or esparto pulp approx. 410 tons of air is circulated. This figure varies between wide limits. An analysis is made of how this air is utilized (e. g., in ventilation, boiler firing, for conveying purposes, dust removal, drying, humidifying, heating, and conditioning of paper). Louis E. Wise

The use of bitumen in the production of fibrous products. Fritz Ohl. *Wochbl. Papierfabr.* **70**, Tech. Tl. 903–4 (1939).—Description of the incorporation of bitumen in paper, pulp and paperboard. Louis E. Wise

Retention of aluminum ion and hydrogen ion in papers. Herbert F. Launer. *J. Research Natl. Bur. Standards* **23**, 663–74(1939) (Research Paper No. 1262); cf. *C. A.* **33**, 6593⁴.—The lower pH of the soln. obtained by the extn. of paper with hot rather than with cold H_2O is attributed to increased hydrolysis of the Al salts in the paper. It is shown that neutral paper fibers selectively adsorb Al ions; hence the amt. of Al salt in the paper is much larger than would be expected from the concn. in the soln. used in its manuf. The addn. of fibers to an Al soln. raises the pH by an amt. depending on the nature of the fiber and the concn. of the soln. The pH changes observed on heating Al solns. are greater in the presence of paper fibers than in their absence. The addn. of rosin decreases the acidity of paper and also the difference in pH resulting from hot and cold extn. This is attributed to the formation of insol. Al resinate. S. Glasstone

Combating resin difficulties in paper mills. M. N. Beletskaya. *Bumazhnaya Prom.* **17**, No. 11, 28–36 (1939).—The literature on the nature and the methods of combating the injurious resins is discussed (cf. Konopatzkiĭ, *C. A.* **30**, 3230⁶). Storing unbleached pulp at 40° for 10 days eliminates the contamination of beaters, paper machine and the paper, because of the oxidation of injurious resins (volatile cymene hydrocarbons and unsatd. aliphatic acids). The best effect is obtained by adding 0.2% of NaOH on the wt. of fiber in the process of beating. The subsequent addn. of $Al_2(SO_4)_3$ aids in a more complete fixation of the sol. resins on the fiber. Chas. Blanc

The extractor press in the machine used in manufacturing carton. Wilhelm Spahr. *Wochbl. Papierfabr.* **70**, Tech. Tl. 913–14(1939).—The advantages of this press are indicated in practical mill runs. Louis E. Wise

Preservatives used in the paper, carton and board industry. Fritz Ohl. *Wochbl. Papierfabr.* **70**, 839–41 (1939).—There appears to be no one universal preservative. The toxic effects of Hg^{++} salts and fluorides must be considered when edibles are stored in paper containers. HCHO may cause discoloration of packed rayon materials. Relatively large amts. of H_3BO_3 and 2-$HOC_6H_4CO_2H$ are required for effective preservation. Preservative manufacturers should know what specific materials and chemicals are used in subsequent paper manufg. conditions of operation, temps., pH, etc. Special attention is drawn to *chlorothymol* with its very high phenol coeff.; *chlorocarvacrol*, various salts of chlorophenol and the chlorocresols, *chloramine T*, *chloroxylenols*, *hexylresorcinol*, 2-HOC_6H_4Ph (which is relatively harmless to man, but has a phenol coeff. of 20, and which actually improves sizing). Combinations of preservatives are often essential in special cases. Substituted phenols with long side chains, while excellent preservatives, are impractical because of their insoly. in H_2O. Louis E. Wise

Casein, its production and uses [in paper industry] (Wickman) **13**. Comparison of imperviousness of commonly used paper milk containers when in contact with contained liquids (Stoltz, Armstrong) **12**. Photomicrographic measurement of units of vegetable fibers (Vikhrov) **25**. Compns. for softening paper (U. S. pat. 2,180,133) **29**.

Deutsches Papiermacher-Jahrbuch, 1939. Kalender der Papier-Industrie. Handbuch für den Papiermacher. Schotten: W. Engel. 390 pp. M. 3.

Regenerated-cellulose pellicle. Thomas F. Banigan (to E. I. du Pont de Nemours & Co.). U. S. 2,179,571, Nov. 14. A softened, wet, regenerated-cellulose pellicle is formed which is subject to shrinking by loss of water and is subject to staining when shrunk in contact with iron, and which contains sufficient triethanolamine, tripropanolamine or tributanolamine to prevent rusting of iron when the pellicle is dried in contact with iron.

Wood cellulose for the manufacture of cellulose derivatives such as cellulose acetate. Lionel E. Goff (to Cellulose Research Corp.). U. S. 2,180,517, Nov. 21. A process of converting unbleached sulfite wood fibers into a permeable network of activated cellulose comprises removing the ligneous material by treatment of the fibers with an amt. of Cl that is exhausted in the order of 20–30 min., removing the reaction products with dil. alkali, removing oxidizable material by a hypochlorite bleach, terminating the bleach having a pH greater than 7.4 before the cellulose is substantially degraded, and rendering the residual membranous material permeable by boiling in NaOH soln. of about 7% concn. Cf. *C. A.* **34**, 1172[9].

Precipitating cellulose triacetate. Carl J. Malm (to Eastman Kodak Co.). U. S. 2,180,009, Nov. 14. For pptg. substantially fully acetylated cellulose from a reaction mixt. in which it is dissolved, the reaction mixt. is introduced into a pptg. bath of HOAc of 40–60% strength and the strength of the pptg. bath is maintained throughout such introduction; the ester is removed from the pptg. bath and is treated with hot water until a product is obtained which upon drying is soft and nonborny.

Forming products such as filaments and threads from solutions of cellulose derivatives such as cellulose acetate. Wm. A. Dickie and Percy F. C. Sowter (to Celanese Corp. of America). U. S. 2,179,544, Nov. 14. A liquid coagulating medium is used, and the product, after coagulation, is subjected to the action of a liquid such as an acetone mixt. contg. at least 50% of nonsolvent plasticizing agents for the cellulose deriv. material, such as tritolyl phosphate or diethyl phthalate.

Apparatus for the manufacture of artificial filaments from materials such as viscose or cellulose esters. Louis S. Fryer (to Industrial Rayon Corp.). U. S. 2,181,052, Nov. 21. Various structural and operative details.

Cellulose ester compositions suitable for films, threads, coatings, molded products, etc. Lucas P. Kyrides (to Monsanto Chemical Co.). U. S. 2,180,281, Nov. 14. A mono-*N*-cyclohexyl aromatic sulfonamide of the benzene series such as *N*-cyclohexyl paratoluenesulfonamide is used as a plasticizer with cellulose esters such as cellulose acetate or nitrate.

Animalization of textile fibers. I. G. Farbenind. A.-G. Fr. 841,158, May 12, 1939. The coloring properties of wool are conferred upon artificial fibers by incorporating into the latter polymerization products, contg. N and resistant to acids and alkalies, obtained by the reaction of ethylenimine, its polymers or homologs with isocyanates or isothiocyanates. The polymerization products suspended in higher alcs. or in aromatic amines are added to the spinning solns. of cellulose, acetylcellulose or other artificial substances and emulsified. Among examples, 200 g. of the polymerized product dissolved in 500 g. cyclohexanol is emulsified with 10 l. viscose and subjected to known spinning treatments. The fiber differs from normal fiber only with respect to the coloring properties.

Circulation of groundwood stock. V. Calvin Harvey. Can. 386,113, Jan. 9, 1940. Operative and structural details are described of an app. for continuously conveying the groundwood stock output of several grinders mixed with water to a storage tank by jets spaced within the tank to mix the output intimately prior to delivery to a papermaking machine.

Circulation system for wood-pulp digesters. Einar Morterud. U. S. 2,179,796, Nov. 14. Various structural and operative details.

Apparatus for refining paper stock. Edwin Cowles (to The Cowles Co.). U. S. 2,180,080, Nov. 14. Various structural and operative details.

Shaking-mechanism for Fourdrinier papermaking machines. Bernard A. Malkin. Brit. 506,625, June 1, 1939.

Two-layer drier felt for papermaking apparatus. Thomas Hindle and Sam Lord. U. S. 2,180,054, Nov. 14. Various structural details.

Refining clay such as that for use in coating paper. Sanford C. Lyons (to Bird Machine Co.). U. S. 2,180,742, Nov. 21. A process of refining an aq. clay suspension contg. Fe_2O_3 as a coloring impurity, in which the Fe_2O_3 is reduced to a substantially colorless, water-sol. ferrous salt, involves treating the suspension contg. the dissolved ferrous salt formed with sufficient alkali metal polymetaphosphate to inhibit reversion of such salt to Fe_2O_3 and sepg. the clay from the suspension. Cf. *C. A.* **33**, 4036[3].

Ornamental coloring of paper. Ethan F. Bassford (to George La Monte & Son). U. S. 2,180,387, Nov. 21. App. is described, and a method of making ornamentally colored paper which comprises making paper having portions of a surface thereof of substantially differing absorptiveness for a liquid colored material, portions of lesser absorptiveness being of predetd. form, and producing a shaded effect in local areas adjoining the portions of lesser absorptiveness by successive applications of the coloring material, one application of the coloring material being an all-over application thereof to the surface of the paper, and another application of the colored material being made by spreading free coloring material from portions overlying the portions of lesser absorptiveness onto the adjoining local areas of the surface having greater absorptiveness.

Removal of printing ink from paper. Berthold Rassow and Edgar Herferth. Fr. 841,053, May 10, 1939. The fibrous material is treated with an aq. soln. of a pyrophosphate of an alkali metal or of NH_4.

Cigaret paper. Earle C. Pitman (to E. I. du Pont de Nemours & Co.). U. S. 2,179,953, Nov. 14. A discontinuous coating of a wax m. about 60°, such as a petroleum wax, and a mineral oil is used for prepg. a water-resistant cigaret paper.

24—EXPLOSIVES AND EXPLOSIONS

C. G. STORM

Calorimetry of explosives. E. Burlot, M. Thomas and M. Badoche. *Mém. poudres* **29**, 226–82(1939).—Sources of error in calorimetric tests have been investigated. With a solid explosive (dinitrophenol) the C. S. E. bomb gave the max. value for heat of combustion, but with a liquid explosive (nitroglycerin) divergencies were greater. Max. and mean divergencies in the value of *Q* for tetryl, trinitro-*m*-cresol, dinitrophenol, tri- and di-nitrophenetole, $C_6H_2Me(NO_2)_2$ and $NHPh_2$ were 0.05, 0.03; 0.07, 0.04; 0.0[2], 0.01; 0.07, 0.03; 0.05, 0.03; 0.08, 0.03 and 0.09, 0.03. Heats of combustion and formation of 25 nitrated products and 2 amines are tabulated. Corrections to be applied and precautions in connection with complete combustion, deposition of C, destruction of the pan, and attack on the Ni electrodes, are discussed. A. J. Phillips

Influence of moisture on the Abel heat test for nitroglycerin at 80°. R. Vandoni. *Mém. poudres* **29**, 204–5 (1939).—Nitroglycerin after distn. at 50°/0 003 mm.,

when dry, contg. 0.8% moisture and satd. with H_2O gave heat tests of 21, 30 and 45 min. Its resistance is therefore related to its moisture content. A. J. Phillips

Verification of the law of combustion of colloidal powders. H. Muraour and G. Aunis. *Mém. poudres* 29, 197–203, 211–15(1939).—Satisfactory agreement between exptl. and theoretical calcns. was obtained with cylindrical, semicylindrical and tubular powders contg. nitroglycerin and centralite, and Et centralite with Et phthalate when fired in a 150-cm. bomb. A. J. Phillips

Decomposition of nitrocellulose as a result of varied treatments. J. Desmaroux, R. Vandoni, L. Brissaud and Mlle. T. Petipas. *Mém. poudres* 29, 134–96(1939).—Nitrocellulose decomps. in 3 ways which may take place simultaneously but at different rates of speed, namely (1) by hydrolysis of the glucose linkages, (2) sapon. of the NO_3 groups and (3) oxidation of the glucose framework. (1) can be detd. by measurements of osmotic pressure or viscosity, (2) by decrease in percentage of N and (3) from CO_2, CO and CH_4 measurements. Details are given for the purification of ramie fiber and samples of nitroramie contg. 14, 13.75, 12.78, 12.10, 11.88 and 11.33% N were prepd. and heated for various periods (*a*) in 25% HNO_3 at 50°, (*b*) in distd. H_2O in sealed tubes at 120° and (*c*) at 108.5° in absence of O_2, to study their methods of decompn. In (*a*) the gaseous products were measured and the loss in weight owing to loss of N, soln. and oxidation of nitroramie calcd. Curves are given for loss in wt. by soln., rate of hydrolysis as a function of N content, combustion and sapon. Similar curves are given for (*b*). For (*c*) the vol. of evolved gas is given as a function of time, the heating being carried out in a vertical tube with connections at the base to limit contact of nitrocellulose with decompn. products. The nitrocellulose was converted into a residual mass which gave no further amts. of gas owing to exclusion of O of the air. X-ray examn. of samples from (*a*) and (*b*) showed the structure of trinitrocellulose is still present even when denitration has lowered the N content to 11%. In no case was a diagram for cellulose found. A. J. P.

Loss in weight at 75° of nitrocellulose and other substances impregnated with nitroglycerin. J. Chédin. *Mém. poudres* 29, 95–110(1939).—The materials tested were ballistite paste, 2 samples of SD paste, and bleached cotton linters impregnated with nitroglycerin and dynamite. Results were calcd. from actual loss in weight and from the results of extn. with $CHCl_3$, the figures by the 2 methods agreeing within 1–2%. The dynamite lost all of its nitroglycerin and differences in the rates of evapn. from the different substances are attributed to differences in total surface exposed from which evapn. takes place. Further tests were made with 2 SD pastes, mercerized cotton, nitrated mercerized cotton (11.84% N), nitrated hydrocellulose (12.16% N), CP_2 film (11.74% N), and CP_1 (13.46% N). For bleached cotton linters, mercerized cotton and kieselguhr (in dynamite) the losses were in accord with the equation $dy = Kydt$, there being no indication of chem. affinity but only adsorption. With ballistite and SD pastes and the other nitrated products evapn. occurs according to $\log y/y_0 = Kt$. Some residual nitroglycerin equiv. to 5–6% of the nitrocotton is fixed and not evapd. according to this formula. It is considered that either the structure of the nitrocellulose or the NO_2 groups is responsible for this fixation and that gelatinization which begins during the heating period is not responsible. No significant differences were found in the amt. of fixation in samples whose N content varied from 11.7 to 13.46%. The gelatinized CP_2 film lost the smallest amt. of nitroglycerin owing to its small amt. of evapg. surface. Nitroglycerin above 5–6% is held by adsorption as indicated by x-ray examn., there being no visible trace of nitroglycerin present. A. J. Phillips

Hazard of static electricity during surgical anesthesia with oxygen-ether mixture. M. H. Remund and S. Wehrli. *Schweiz. med. Wochschr.* 69, 660–2(1939).—Static charge of the insulated table and patient apparently caused 2 explosions when ether and O mixts. were used during surgical anesthesia. Grounding of all app. is advisable. Maurice M. Rath

The induction period in thermal explosions. D. A. Frank-Kamenetskii. *J. Chem. Phys.* 8, 125–6(1940); cf. *C. A.* 33, 6049⁹.—The calcn. of the induction period, as done by Rice and Campbell (*C. A.* 33, 8015⁶), "cannot be regarded as an appropriate method for comparing the theory of thermal explosions with expt. and, in particular, for computing the thermal effect of explosive reactions." The reasons are based on the geometry of the app. and the technique of the expt. G. M. Petty

Serious explosion in a wood-flour factory. Reutlinger. *Feuerschutz* 19, 157–8(1939).—The wood-flour explosion and subsequent fire in a German factory was caused by heating due to friction during the grinding of the wood flour; the grinding stones were too close together. Recommendations are made for the construction of such hazardous industrial plants. Leopold Scheflan

Fire in a leather factory. Brunswig. *Feuerschutz* 19, 154–6(1939).—The use of modern combustible lacquers and dye solvents in leather factories is a serious fire hazard. A typical fire in a German leather factory is described and methods of avoiding similar happenings are suggested. Leopold Scheflan

Al paint as fire hazard (National Safety First Assocn.) 26.

Davis, Harold Joe: Industrial Hazards of Static Electricity. Tulsa, Okla.: The Author. 10 pp. 25 cents.

Table of Common Hazardous Chemicals. Prepd. by Comm. on Hazardous Chemicals and Explosives of National Fire Protection Assoc. and Am. Chem. Soc. under direction of G. W. **Jones and A. H. Nuckolls.** 4th ed. Boston: National Fire Protection Assoc. 24 pp. 20 cents.

Picryl fluoride and explosives containing it. Laurence G. Wesson (to Veader Leonard). U. S. 2,179,605, Nov. 14. Picryl fluoride, a brownish yellow compd. m. about 150–160°, is made by treating picryl chloride with F (using NaF and HOAc) and is used in explosives such as those for bombs or shells.

Electric fuseheads as used in blasting detonators. Wilfrid Taylor and Cecil R. L. Hall (to Imperial Chemical Industries Ltd.). U. S. 2,180,129, Nov. 14. At least one face of a sheet of rolled brass foil is subjected to an etching treatment, as by the use of an NH_3 soln., and the etched face is secured to an insulating material such as pressboard by a thermoplastic cement such as a polyvinyl acetate compn.

Miners' and other lamps. Oldham and Son Ltd. and Harry Holt, Jr. Brit. 506,019, May 22, 1939. Addn. to 478,068 (*C. A.* 32, 4788⁴).

25—DYES AND TEXTILE CHEMISTRY

L. A. OLNEY

Recent progress in the field of ice colors. P. Predelli. *Atti X° congr. intern. chim.* 4, 250–6(1939). E. H.

The relationship of coal tar and pure vegetable dyes. J. W. Orelup. *Progressive Perfumery & Cosmetics* 1938, 99–100.—A discussion of the connection between the structure and chemistry of dyes. Leopold Scheflan

The absorption of substantive dyes by cellulose from solutions of very high dye and salt concentrations. S. M. Neale and W. A. Stringfellow. *J. Soc. Dyers Colourists* 56, 19–21(1940).—An attempt is made to find some upper limiting value to the absorption of dyes by making use of the highest concns. of dye and salt attainable without causing pptn. of the dye. The absorption under conditions approaching satn. is influenced by swelling or by oxidation

of the cellulose in the same way as it is for normal dyeings. W. H. Boynton

Note upon the absorption of the substantive dye Sky Blue FF by cotton cloth dyed with the vat dye Cibanone Orange R. S. M. Neale and W. A. Stringfield. *J. Soc. Dyers Colourists* **56**, 21–3(1940).—A comparison of the absorptive capacity of a sample of oxycellulose having both acidic and reducing properties due to "accelerated" oxidation and an ordinary oxycellulose having the same —COOH value. The unoxidized specimen contg. approx. 1% of vat dye had a decidedly higher absorption value for Sky Blue FF than the original untreated yarn, whereas the effect of accelerated oxidation had brought about a much smaller decrease in substantive dye absorption than that shown by cotton oxidized to the same—CO-OH value by the direct action of alk. hypobromite. Results are tabulated. W. H. Boynton

Adsorption of naphthols in the presence of different electrolytes and peptizing agents and at different temperatures. J. A. Nabar, P. M. Barve, A. M. Patel and B. N. Desai. *Proc. Indian Acad. Sci.* **10A**, 344–58(1939).—Cotton cloth was dyed with Naphthol AS-G, Naphthol AS, Naphthol AS-TR, Naphthol AS-BO and Naphthol AS-SW. Concns. of dye in solns. before and after immersion of cloth were detd. by titration with Trivasol Red TR. Addn. of alc., gum tragacanth, and agar-agar lowered the amt. of dye adsorbed. For low concns. of NaOH, NaCl, Na sulfate, Na phosphate, and soap the amt. of dye adsorbed was increased; as the concn. was increased, the adsorption passed through a max. and then decreased. At higher temp. the rate of adsorption was greater and at equil. the amt. of adsorbed dye was greater than at low temp. The effect of temp. appeared to be more marked for dyes of higher substantivity. Donald C. Bond

The dyeing properties of new fibers. H. M. Bunbury. *J. Textile Inst.* **30**, P172–80(1939).—See *C. A.* **33**, 6601[3]. R. K. Worner

Dyeing of yarn in the Brandwood apparatus. N. A. Bazarov, N. A. Yushkov and N. A. Shubina. *Byull. Ivanovo Nauch. Tekh. Issledovatel. Inst.* **1938**, No. 4–5, 90–6; *Khim. Referat. Zhur.* **2**, No. 4, 124–5(1939).—To correct unevenness in dyeing, the following changes in the process were introduced. (1) For dyeing, a condensate or preliminarily softened water was used instead of the hard water which formed a ppt. on the surface of the bobbin. (2) The mother liquors of the dyes were allowed to stand for 24 hrs. to sep. the mech. admixts. (3) The method of wetting was simplified. (4) A method was developed for the prepn. of the mother liquor in the dyeing bath. To reduce the concn. of the dyeing bath an electrolyte (NaCl, from 200 to 400%) was added which gave a 25–50% saving of the dye. (5) The max. temp. for each color was detd. W. R. Henn

New methods for diazotype printing. T. W. A. Borgesius and H. I. Waterman. *J. Soc. Dyers Colourists* **56**, 236(1940).—A description of an investigation of the possibility of prepg. paper for diazotype printing, starting from proteins, particularly casein. Casein changes by treatment with HNO_2 into a yellow compd. which becomes brown with alkalies and gives darker colored coupling products with various aromatic amino and hydroxy compds. Paper was successfully coated with diazo-casein to permit its use for printing purposes. Light sensitivity is great and the fastness to light of the prints is good. Prints of sufficient intensity were not obtained but research is being continued. W. H. Boynton

Acid or gas or atmospheric color fading on dyed acetate rayon goods. Herbert R. Mauersberger. *Rayon Textile Monthly* **21**, 109–11(1940).—Gas fading occurs on solid colored acetate goods, dyed in a single operation. The shades affected are generally in colors in which blue occurs or is a part such as greens, navies, grays, violets, tans, black, blue-reds, etc. Gas fading occurs in fabrics made from acetate yarns irrespective of the source of the yarn and in mixed goods where acetate rayon is used for warp and viscose for filling. All viscose rayon goods do not show gas, acid or atm. fading. The gases involved in the fading seem to be those formed by the combustion of illuminating gases, elec. coils, gas burners, etc. Inhibitors are somewhat effective but not certain in results. W. H. Boynton

The removal of dyes from textiles by rubbing. Olgerts Ripa. *Acta Univ. Latviensis, Kim. Fakultat.* Ser. 4, No. 12(in Lettish, 455–68; in English, 469–71)(1939).—A dyed textile 4 × 25 cm. was fastened about a wooden pulley. Tangent to the pulley was a wooden lever wrapped with a white fabric which accumulated the dye from the rubbing. After 100 revolutions the dye adhering to the white fabric was evaluated with a Pulfrich photometer. Tables give the dye rubbed off in relation to speed of rotation, pressure, no. of revolutions, size of rubbing surfaces, and size of dye particles. Frank Maresh

Wood's light. François Dervaux. *Tiba* **17**, 555, 557, 591, 593(1939); cf. *C. A.* **33**, 9002[9].—An address dealing with the use of ultraviolet light for testing purposes in the textile and dyeing industry. A. Papineau-Couture

Microphotographic measurement of the units of vegetable fibers. V. E. Vikhrov. *Bumazhnaya Prom.* **17**, No. 10, 29–31(1939).—A single procedure is suggested for projecting a magnified microscope image of a stained prepn. on a photographic paper and measuring the fiber units with the aid of a calibrated plate. Chas. Blanc

A chemical method for the preparation of hemp fibers. V. M. Bondarenko. *Len i Konoplya* **5**, No. 10, 41–3 (1938); *Khim. Referat. Zhur.* **2**, No. 4, 126(1939).—Pectin substances were destroyed and the fiber was freed from the accompanying components by treating hemp straw with H_2SO_4 and starch paste. The acid hydrolyzed starch to glucose and formed an acid medium in which pectin produced a gel that was washed away. The acid was neutralized with wood ash. A fiber was obtained which was equal to that obtained by natural retting in color strength and elasticity. Good results were also obtained by treatment with wood ash or with ash obtained from the combustion of malt grains from alc. distilleries. W. R. H.

Apparatus for measurements of lengths of cotton fibers. Burt Johnson. *Ark. Agr. Expt. Sta., Bull.* **381**, 22 pp. (1939).—The construction and operation of a mech. fiber comber for seed cotton is given. A photoelec. cotton fiber sorter for seed cotton is also described. C. R. Fellers

The problem of the measurement of the fineness of wool. H. J. Henning. *Klepzig's Textil-Z.* **43**, 36–45(1940).—A detailed description of phys. methods of measurement. 12 references. Leopold Scheflan

The degumming of natural silk. Joseph Nivière. *Rusta-Rayonne* **14**, 427, 429, 455–9(1939).—A brief discussion of the nature and compn. of sericin, the purpose of degumming, the properties required of soap for degumming and processes (diastases, alkalies) which have been tried (unsuccessfully) to replace washing with soap. A. Papineau-Couture

Lipase for defatting of silk waste products. M. V. Korchagin. *Uchenye Zapiski Fakul'teta Estestvozn. Moskov. Gosudarst. Pedagogicheskogo Inst. (Lab. Org. i Biol. Khim.)* **1938**, No. 3, 113–29; *Khim. Referat. Zhur.* **2**, No. 4, 126 (1939).—Waste products of the silk industry can be defatted by a prepn. from pig pancreas contg. 0.12–0.15% (on the wt. of silk) of enzyme with lipolytic index 1. The dependence of fat removal on the concn. of the enzyme, the time of action and the pH were detd. Max. activity was found at pH = 8.0–9.0. W. R. Henn

Progress in the staple-rayon industry. H. G. Bodenbender. *Chem.-Ztg.* **63**, 669–72, 677–9(1939). E. H.

"Tenasco." L. Rose. *J. Textile Inst.* **30**, P202–9 (1939).—"Tenasco" is the registered name given by Courtaulds Ltd. to high-tenacity yarns made by a modification of the ordinary viscose-spinning process. The conditions of stretch spinning are chosen so as to yield a dry tenacity considerably higher than normal and depending on the requirements of service. The fibers are particularly suitable for use in industrial textiles, such as tire cords. Ruby K. Worner

Factors affecting the service qualities of certain textile fabrics. K. Hess; Esther Nelson and Hazel Fletcher. *Kansas Agr. Expt. Sta., 9th Biennial Rept.* **1938**, 121–2.—Tests on various com. soap powders and bleaching agents

are discussed. A new method was devised for measuring the absorptive properties of fabrics such as Turkish towels. It consists of allowing water to drop from a pipet on a sample of the fabric, of known dimensions and wt. until a drop of water comes through. A factor representing the absorption capacity was calcd. by multiplying the no. of cc. of water and dividing by the wt. of the sample in g. Slightly higher results than are obtained by use of the porous porcelain disk method were obtained. C. R. F.

The action of alkylene oxides on cellulose. L. G. Lawrie, R. J. W. Reynolds and D. Ward. *J. Soc. Dyers Colourists* **56**, 6–17(1940).—The treatment of cotton material, previously activated wth NaOH, with controlled quantities of $(CH_2)_2O$ resulted in a marked change in the properties of the material. Other alkylene oxides act similarly. The stiffness and transparency of the cloth are enhanced and the cloth lends itself remarkably well to a variety of finishing treatments. Chem. considerations relating to the reaction and the mode of application and a wide variety of finishes obtainable are indicated. In practice the fabric is impregnated or printed with aq. NaOH soln. and in the case of impregnation, the excess removed by expressing in a mangle, or by hydro-extn. The impregnated cloth without drying is then treated with $(CH_2)_2O$ in soln. or as a gas. The cloth is acidified, washed and bleached, and finally washed and dried. Subsequent finishing processes are applied. The steps of the above procedure are discussed separately. The strength of the $(CH_2)_2O$-treated cloth, the dyeing properties of $(CH_2)_2O$-treated cotton and the use of other alkylene oxides are noted. The effects so far produced by the reaction of $(CH_2)_2O$ on cotton material treated with NaOH are grouped for description purposes as follows: over-all effects; (*a*) organdie-like, (*b*) linenized and (*c*) parchmentized and printed effects, (*d*) window-pane, (*e*) printed damask, (*f*) figured velveteen, and (*g*) "lace." Basic conditions for the production of the various effects in CCl_4 which have been successfully employed in practice are summarized. Expt̄l. work on $(CH_2)_2O$ treatment of viscose rayon, linen and jute indicates some outstanding advantages on these fibers. W. H. Boynton

Washing wool and rayon fabrics. A. Foulon. *Seifensieder-Ztg.* **67**, 2–3, 12–13(1940).—Review. A. Guillaudeu

The bleaching of cotton linters. Eugène Roux. *Tība* **17**, 573–7(1939).—A brief outline of the principal methods used commercially. A. Papineau-Couture

Catalytic damage to bleach [for textiles]. G. Dierkes. *Klepzig's Textil-Z.* **43**, 46–50(1940).—Ferrous and ferric iron in water cause decompn. of peroxide liquors, the rate of which increases with increasing alky. The catalysis can be repressed and the evolution of O can be regulated by the use of stabilizers. Hard waters low in Fe are suitable without treatment for the peroxide bleaching process. Leopold Scheflan

Boiling of mixed textiles in Van-Flanderen apparatus. S. S. Frolov and V. M. Rybakova. *Byull. Ivanovo Nauch. Issledovatel. Tekh. Inst.* **1938**, No. 4–5, 81–5; *Khim. Referat. Zhur.* **2**, No. 4, 125(1939).—The app. is used for the treatment of crêpes from artificial silk with NaOH or with a caustic soap. The boiled and bleached textiles had high capillarity, slightly decreased strength, high ash content and a high extn. no. The app. preserves the structure of the textiles. W. R. Henn

Boiling of textiles containing mechanical cottonin. N. Kozhin and I. Yumanov. *Byull. Ivanovo Nauch. Issledovatel. Tekh. Inst.* **1938**, No. 4–5, 85–90; *Khim. Referat. Zhur.* **2**, No. 4, 125–6(1939).—The brownish streaks found after boiling textiles made of the lower grades of cotton and mech. cottonin are compds. of Ca or Mg with adsorbed org. substances of the boiling alkali. The ash content of textiles with streaks is considerably higher than that of pure textiles (2.84% against 0.07–0.12%). Oxides of different metals were found in the ash which were evidently introduced by the textiles and mainly by water. Different softeners for water were tried to improve the quality of water. Best results were obtained from boiling with $Na_2Si_4O_9$. A soln. for boiling was developed which contained NaOH 192 kg., Kontakt 30 kg. and silicate of 30°Bé. 40 kg. W. R. Henn

The use of sodium hydroxide in boiling of cotton. N. Kozhin and N. Mokhova. *Byull. Ivanovo Nauch. Issledovatel. Tekh. Inst.* **1938**, No. 4–5, 77–80; *Khim. Referat. Zhur.* **2**, No. 4, 125(1939).—The amt. of NaOH needed for bucking and the loss of wt. of cotton were investigated with 6 samples of cotton and cottonin. The loss of wt. depends mainly on the grade of cotton; a preliminary treatment of the cotton has an insignificant effect. Impurities in cotton have a decided effect on the amt. of NaOH required. Boiling of 1st-grade cotton (freed from mech. impurities) takes 1.52% of NaOH while 5.03% is needed for boiling the impurities taken from the cotton. W. R. Henn

The shrinking of textiles during wet washing and chemical dry cleaning. H. Rath, A. Enz, J. Middelhoff and E. Schäffer. *Klepzig's Textil-Z.* **43**, 29–35(1940); cf. *C. A.* **34**, 1183⁷.—Samples of cotton, a mixt. of staple rayon and cotton, staple rayon, staple rayon muslin, cotton flake, and damask from a mixt. of cotton and staple rayon, resp., were washed by standard procedures with aq. and nonaq. solns. (Asordin) and changes produced in various phys. properties are shown in detail. Chem. washing causes less shrinking than aq. washing. In general most of the shrinking is reached after the fifth washing. L. S.

The resistance of linen and hemp fabrics to weathering and rotting. Werzmirzowsky. *Melliand-Textilber.* **21**, 12 14(1940).—Samples of sand-bag fabric made (*a*) from hemp and (*b*) from linen both unimpregnated and treated with $CuSO_4$ soln. were exposed for 1–6 months (1) to the weather at high altitude in the Riesengebirge, in central Germany and on a North Sea island, (2) stored in a room kept at 18 20° with a relative humidity of 80–90% and (3) buried under a 10-cm. sand layer kept at about 20°. Tabulated data show that loss in strength was less in all cases for the fabric made from hemp. The impregnated fabrics showed less loss in strength for all cases except the samples exposed to the weather. Impregnated samples so exposed showed a loss in strength which increased proportionally with the amt. of light falling on the sample with the result that the loss in strength for some of the impregnated samples was greater than that of corresponding unimpregnated samples. Azo dyes. Gerald Bonhote and Carl Apotheker (to Soc. pour l'ind. chim. à Bâle). U. S. 2,176,521, Oct. 17. By the reaction of diazo compds. such as those of aniline, 2,5-dichloroaniline, 1- or 2-naphthylamines or various other specified components with a nonsulfonated 2'-arylpseudonaphthazimide hydroxylated in the 2-position of the naphthalene nucleus and contg. no hydroxyl group in the 2'-aryl residue, dyes are obtained of the general formula

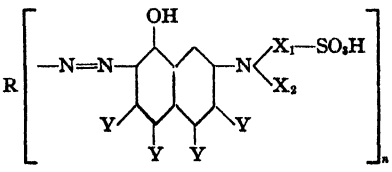
where R stands for an aromatic radical of the benzene or naphthalene series, two *x*'s stand for H atoms and one *x* stands for a hydroxyl group, the two *y*'s which stand in *o*-position to hydrogen atoms standing also for H atoms and the *y* standing in *o*-position to a hydroxyl group standing for a radical —N:NR$_1$, in which R$_1$ stands for an aromatic radical of the benzene or naphthalene series, which are dark powders which when produced on vegetable fiber dye the same reddish yellow to red, violet, blue, brown and black tints of good fastness.

Azo dyes. Friedrich Felix and Rudolf von Capeller (to Soc. pour l'ind. chim. à Bâle). U. S. 2,177,427, Oct. 24. From components such as 2,6-dichloro-4-nitroaniline and the Na salt of 6-ethoxy-3-methyl-2'-sulfodiphenylamine, etc., dyes are produced of the formula Cx:CH.C(N:NR$_1$):Cy.CH·CNHR$_2$, where R$_1$ stands for an aromatic isocyclic 6-membered nucleus, R$_2$ stands for a sulfonated aromatic, isocyclic six-membered nucleus, and *x* and *y* stand for org. substituents of nonionogenic nature, which dyes are light to dark powders which are sol. in water and dye textiles such as wool, silk and acetate rayon yellow, red, violet, brown and blue tints. Numerous examples are given.

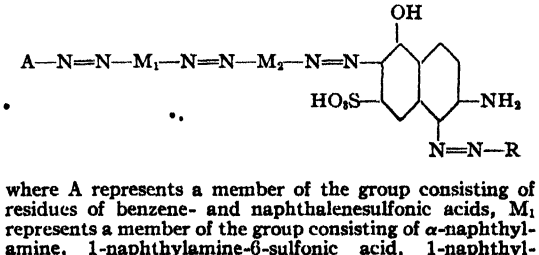
Azo dyes. Hans Krzikalla and Wolfgang Alt (to General Aniline Works). U. S. 2,181,057, Nov. 21. From components such as 2-acetoxynaphthalene-3-carbonyl chloride and Na 4,4'-diaminobiphenyl-3,3'-di-ω-methanesulfonate, etc., dyes are produced which are suitable for dyeing wool, silk, viscose, rayon, etc., and which have the general formula



where R and Ar represent aromatic radicals, and wherein X stands for an arylene radical contg. at least one salt-forming member of the group consisting of sulfonic and carboxylic acid groups, which groups are externally attached to the arylene radical by means of an aliphatic chain.

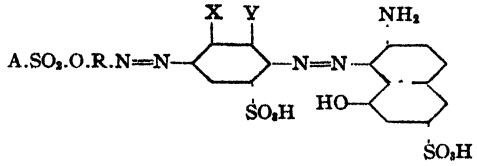
Azo dyes. Leopold Laska, Arthur Zitscher and Rudolf Heil (to General Aniline Works). U. S. 2,180,297, Nov. 14. Dyes are produced of the general formula [1-[3-(—HNCO)-2-(HO)RN:N]-2-X-4-(N:C)-5-XC$_6$H$_2$]$_n$R$_1$ where *n* stands for one of the members 1 and 2, the X's stand for members of the group consisting of halogen, alkyl, alkoxy, phenoxy, trifluoromethyl, alkylsulfonyl and dialkylaminosulfonyl, R means a member of the group consisting of naphthalene, halogen-substituted naphthalene, alkoxy-substituted naphthalene, carbazole, benzocarbazole and anthracene, and R$_1$ a member of the group consisting of radicals of the benzene, naphthalene and biphenyl series, yielding, when produced on the fiber, orange to blue and brown dyeings of good fastness particularly to light. Numerous examples are given.

Azo dyes. Compagnie nationale de matières colorantes et manufactures de produits chimiques du Nord réunies établissements Kuhlmann. Fr. 840,951, May 8, 1939. The dyes, *p*-[2(or 4)-aminonaphthylazo]mono-, di- or trihaloanilines, are prepd. by diazotization of halogenated *p*-C$_6$H$_4$(NH$_2$)$_2$ and coupling with α- or β-naphthylamine, or by diazotization of a halogenated *p*-H$_2$NC$_6$H$_4$NO$_2$, coupling with α- or β-naphthylamine, and reducing the nitro group. The dyes have great affinity for cellulose esters, and dye cellulose acetate in yellow, orange and brown. Diazotized on the fiber and developed with the aid of the usual coupling compds. they give polyazo dyes of black, green-black, violet and brown shades.



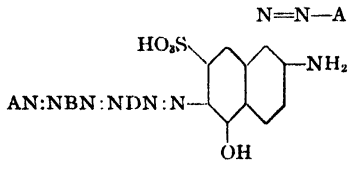
Azo dyes soluble in water. Erich Fischer and Richard Huss (to General Aniline Works). U. S. 2,176,853, Oct. 17. From components such as diazotized sulfanilic acid and 2-(sulfoethylamino)-8-naphthol-6-sulfonic acid dyes are produced of the general formula

where R stands for a member of the group consisting of radicals of the benzene and naphthalene series and biphenyl, *n* means the number 1 when R is a radical of the benzene or naphthalene series and 2 when R is biphenyl, X$_1$ stands for a member of the group consisting of alkyl and hydroxyalkyl and X$_2$ for a member of the group consisting of hydrogen, alkyl and sulfoalkyl, and wherein the naphthalene nucleus contains at least one sulfonic acid group in the positions indicated by Y, which compds. penetrate deeply into *leather* and yield dyeings of various shades. Numerous examples are given.



Monoazo dyes. Richard Fleischhauer (to General Aniline Works). U. S. 2,181,051, Nov. 21. From components such as 2-aminobenzoic acid and 1-acetylamino-3-naphthol-6-sulfonic acid, etc., naphthalene monoazo dyes are obtained of the general formula 1-X-3-HO-4-AN:N-6-NaO$_3$S-8-XC$_{10}$H$_3$, where A stands for the radical of a diazo component of the benzene and naphthalene series contg. in ortho position to the N atom a group capable of being metallized, one X stands for an acylamino group and the other X stands for H, which dye animal fibers various shades of good fastness properties when aftertreated with Cr salts. Numerous examples are given.

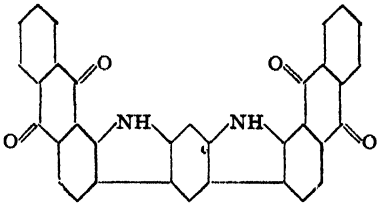
Polyazo dyes. Adolf Krebser (to J. R. Geigy A.-G.). U. S. 2,180,245, Nov. 14. From components such as aniline-*o*-sulfonic acid, 1-naphthylamine-7-sulfonic acid, aminohydroquinone dimethyl ether, metanilic acid and 2,5-aminonaphthol-7-sulfonic acid, dyes are produced which dye cotton greenish blue shades and which have the general formula



where A represents a member of the group consisting of residues of benzene- and naphthalenesulfonic acids, M$_1$ represents a member of the group consisting of α-naphthylamine, 1-naphthylamine-6-sulfonic acid, 1-naphthylamine-7-sulfonic acid, and a mixt. of 1-naphthylamine-6-sulfonic acid and 1-naphthylamine-7-sulfonic acid, M$_2$ represents a member of the group consisting of aminohydroquinone dialkyl and aminohydroquinone diaralkyl ethers, and R represents a member of the group consisting of aminosulfonic acids of the benzene and naphthalene

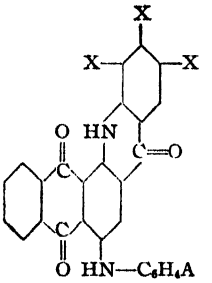
series. U. S. 2,180,246 relates to disazo dyes of the general formula

where X represents a member of the group consisting of H, an alkyl and alkoxy group, Y represents a member of the group consisting of H and an alkoxy group (one, at the most, of X and Y being different from H), R represents the residue of a phenol, coupled in the *p*-position and A represents an aromatic residue of the benzene series, being dark powders, sol. in water with reddish to bluish-violet color, dyeing animal fibers in an acid bath violet shades of good light fastness.



Polyazo dyes. I. G. Farbenind. A.-G. Fr. 841,081, May 10, 1939. The new dyes have the formula

where A is an aromatic radical contg. *o*-hydroxy carboxylic acid groups, and B and D are aminobenzene or aminonaphthalene radicals coupled in position para to the amino group, B and D may also contain sulfonic acid groups. The dyes are obtained by diazotizing disazo compds. of the formula: AN:NBN.NDNH$_2$ (A, B and D having the same significance as in the dyes) and combining them with monoazo dyes, obtained by coupling an aromatic diazo compd. contg. *o*-hydroxy carboxylic acid groups with 2-amino-5-naphthol-7-sulfonic acid. The new dyes dye vegetable fiber in various shades which by a subsequent treatment with a Cu salt are transformed in shades of great fastness to washing and light. Among examples, a disazo compd., obtained by coupling a diazotized *p*-aminosalicylic acid-azoaniline with 3-toluidinemethanesulfonic acid, is combined with the monoazo compd., obtained by coupling, in an acid medium, diazotized *p*-aminosalicylic acid with 2-amino-5-hydroxynaphthalene-7-sulfonic acid. The polyazo compd. dyes cotton in currant shade which by treatment with a Cu compd. becomes black-currant of great fastness to washing and light.



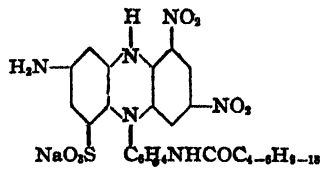
Complex metal compounds of polyazo dyes. Fritz Straub and Walter Hanhart (to Soc. pour l'ind. chim. à Bâle). U. S. 2,180,776, Nov. 21. Numerous examples, with details, are given of the production of complex compds. (suitable *for dyeing and printing cotton*, etc., generally in blue shades) by causing metal compds. such as salts of Cu, Cr or Ni and alk. reducing agents such as alk. solns. contg. glucose to react in the same working operation with azo dyes contg. at least one nitro group in *p*-position to an azo group as well as lake-forming groups, this reaction being carried out in such a manner that in addn. to the metallization of the dye the nitro group is converted into a reduction stage which links two radicals of the azo dye by the azo or azoxy group.

Vat dyes of the anthraquinone series. Georg Kränzlein, Martin Corell and Bernhard Popp (to General Aniline Works). U. S. 2,176,430, Oct. 17. 1,3-Bis(anthraquinonylamino)-4,6-dinitrobenzene compds. of the general formula RHNC:CH.C(NHR):C(NO$_2$).CH:CNO$_2$, where R represents an anthraquinone radical which may contain substituents, may be transformed into very intense and very fast vat dyes by reducing the nitro groups to amino groups and by transforming the 1,3-bis(anthraquinonylamino)-4,6-diaminobenzene compds. thus obtained, by way of the azimino compds. into the dicarbazoles corresponding with the formula

wherein the anthraquinone radicals may contain substituents as, for instance, chlorine, methoxy, phenylamino or benzoylamino. In some cases, it is of advantage to brominate the compd. The dicarbazoles obtained are vat dyes which dye vegetable fiber very intense scarlet, brown and violet tints. They have good fastness, especially to boiling with Na$_2$CO$_3$ and to light. Several examples with details of procedure are given.

Vat dyes of the anthraquinoneacridone series. Erwin Kramer (to General Aniline Works). U. S. 2,180,419, Nov. 21. By reactions such as that of a 4-haloanthraquinoneacridone with a 2-*p*-aminophenylanthraquinone, dyes are formed which dye olive-green shades and which have the general formula

where X stands for H or a halogen, and A stands for a 2-anthraquinonyl group in the *p*-position of the benzene group.



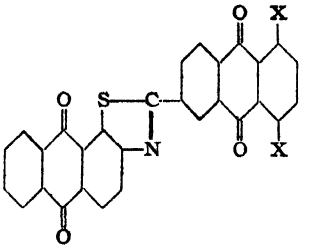
Dyes of the anthraquinone series. Ernst Runne and Ludwig W. Berlin (to General Aniline Works). U. S. 2,176,437, Oct. 17. By various described reactions, there are produced anthraquinones substituted in the 1- and 4-positions by NHX and in the 2-position by CONHY, where Y and one of the X's represents a hydroxyalkyl group and the other X represents H, alkyl or hydroxyalkyl; the compds. being dyes of high soly. which dye closely woven acetate rayon even and intense shades.

Alkyl sulfone dyes of the anthraquinone series. David X. Klein (to E. I. du Pont de Nemours & Co.). U. S. 2,176,630, Oct. 17. Various examples are given of the production of 1-amino-5-alkylsulfonyl-2-anthraquinonesulfonic acids and their alkali salts which carry in the 4-position an alkylamino, arylamino, aralkylamino or cycloamino radical, the alkyl sulfone radical being a methyl sulfone or ethyl sulfone radical, which dye animal fibers bright level blue to blue-green shades.

Wool dyes of the anthraquinone series. I. G. Farbenind. A.-G. Fr. 841,049, May 9, 1939. The dyes are prepd. by combining aminoanthraquinones, anthrapyridones or anthrapyrimidones, which contain residues exchangeable by amino groups, with aminophenylsulfonic aryl-esters or with aminophenylsulfonic arylamides, and sulfonating the products thus obtained. The dyes dye wool even in neutral medium and manifest great fastness to washing. 11 examples are given.

Nitro dyes of the azine series. Richard Fleischhauer (to General Aniline Works). U. S. 2,176,420, Oct. 17. By reactions such as condensation of 1-(*N*-benzoylethylamino)-4-aminobenzene with 1-chloro-2,4-dinitrobenzene-

6-sulfonic acid, etc., dyes are obtained of the general formula



which are black powders sol. in water and dye wool and silk dark reddish brown shades of good fastness to fulling, light, sea water and perspiration.

Dyes of the methine series. Werner Müller and Carl Berres (to General Aniline Works). U. S. 2,179,895, Nov. 14. Dyes giving greenish yellow to orange to violet-red dyeings on cellulose acetate rayon and other materials and probably having the general formula RR_1N—arylene—$CH.C:X$ in which R stands for haloalkyl, R_1 stands for H, alkyl, haloalkyl, hydroxyalkyl, alkoxyalkyl, aralkyl or aryl, the grouping $:C:X$ stands for the radical of a compd. contg. a reactive methyl or methylene group, in which the $:C:$ portion is formed from the reactive methyl or methylene group, and the group RR_1N— stands in *p*-position to CH are obtainable by condensing a compd. with a reactive methylene group with a *p*-aminoaryl aldehyde of the general formula: RR_1N—arylene—CHO, where R and R_1 mean the same as stated. The aldehydes used as starting components in the said process have been described, e. g., in U. S. 2,141,090 (*C. A.* **33**, 2730[1]) and other aldehydes may be used, e. g., *p*-(phenylmethylamino)benzaldehyde and *p*-(ethoxyphenylmethylamino)benzaldehyde. As compds. with reactive methylene groups there may be used, e. g., derivs. of cyanoacetic acid, such as their esters, and amides, further derivs. of malonic acid, such as malonitrile, malonic ester, or the like, pyrazolones, indolines, α-methylindolines, α- and γ-alkylpyridines, alkylquinolines, hydroxythianaphthene, diketohydrindene, acetophenone, dinitrotoluene, etc. Numerous examples with details are given, and by the presence of haloalkyl radicals in the dye mol., a strong displacement of the shade to the short-wave side of the spectrum is effected. Further, the presence of hydroxyalkyl radicals effects in part an essential improvement of the soly. of the dyes, so that particularly dark and abundant dyeings are obtainable. Likewise by haloalkyl, hydroxyalkyl and aryl radicals the fastness to sublimation and to light are improved, particularly in dyeings on acetate rayon. The dyes are also suitable for sensitive Ag halide emulsions.

Dyes of the diphenylamine series. Hans Krzikalla, Heinz Pardon and Fritz Hess (to General Aniline Works). U. S. 2,177,113, Oct. 24. Dyes of good penetration, dyeing yellow to brown shades and suitable for dyeing *leather*, wool and silk or *wood* are produced by causing dinitrobenzenes having exchangeable constituents and also contg. sulfonic or carboxylic groups, such as the Na salt of 2,4-dinitro-1-chlorobenzene-6-sulfonic acid to react with amines of the general formula $\overline{CX_1:CY_1.C(NH_2):CY_2.CX_2:C}NR_1R_2$, in which R_1 and R_2 are hydrogen, alkyl, cycloalkyl or aralkyl radicals, X_1 and X_2 are H or any substituents free from a negative action and Y_1 and Y_2 are H or any desired substituents. Several examples with details are given.

Dyes and dye intermediates of the perylene series. Erich Clar (to E. I. du Pont de Nemours & Co.). U. S. 2,179,920, Nov. 14. 1-β-Naphthoxyanthraquinone is converted to new dye intermediates and dyes by effecting dehydration and condensation by fusing with $AlCl_3$ in the presence of a flux such as NaCl. By this condensation, it appears that there is first formed, at least transitorily, the 3-hydroxy-12,*Bz*-1-oxido-1,2-benzoperylene, which is then converted into the 12,*Bz*-1-oxido-1,2-benzoperylene and 12,*Bz*-1-oxido-1,2-benzoperylene-3,10-quinone. Where the reaction is carried out by the introduction of an oxidizing agent, including air, the 12,*Bz*-1-oxido-1,2-benzoperylene is converted directly to the 3,10-quinone in the reaction mass.

Dyes and dye intermediates of the anthraquinone series. Donald P. Graham (to E. I. du Pont de Nemours & Co.). U. S. 2,179,551, Nov. 14. Compds. of the general formula

in which X stands for substituent amino, arylsulfonylimino, or aroylimino groups, dye tan to reddish brown shades. U. S. 2,179,552 relates to the production of compds. of the general formula of an anthraquinone substituted in the 1- and 4-positions by aroylamino groups of the benzene series and in the 6-position by the group —CONHY where Y stands for an anthraquinone radical directly attached to the N, which dye red to brown shades.

Dye intermediates of the anthraquinone series. Edwin C. Buxbaum (to E. I. du Pont de Nemours & Co.). U. S. 2,180,336, Nov. 21. Details are given of the production of intermediates for producing dyes which, in the form of their sulfonic acids, dye in greener shades of blue of better fastness to light than in the case of similar compds. not contg. the cyano group and suitable for dyeing cellulose acetate rayon. Production is described of anthraquinone (I) intermediates such as: 1-amino-2-sulfo-4-bromo-5-cyano-I; 1-amino-2,4-dibromo-5-cyano-I, m. about 284–8°; 1-amino-2-bromo-5-cyano-I, m. about 228–33°; 1-amino-2,4-dibromo-5-cyano-I; 1-amino-2,4-dibromo-8-cyano-I; 1-methylamino-4-bromo-5-cyano-I, m. about 250–1°; 1-methylamino-2,4-dibromo-5-cyano-I; 1-methylamino-4-bromo-5-cyano-I, m. about 310°; 1-methylamino-2,4-dibromo-8-cyano-I; 1-benzoyl-amino-4-bromo-5-cyano-I; 1-benzoylamino-2,4-dibromo-5-cyano-I; toluylamino-, 1-acetylamino-, 1-formylamino-5- or -8-cyano-I, etc. U. S. 2,180,337 relates to sulfonated dyes and intermediates for their production, of generally like character, such as: 1-amino-2-bromo-4-*p*-toluidino-5-cyano-I; 1-amino-2-sulfo-4-toluidino-5-cyano-I; 1-amino-2-bromo-4-*p*-toluidino-8-cyano-I; 1-methylamino-4-*p*-toluidino-5-cyano-I; and corresponding to toluylamino, acetyl, and formyl compds. of the like aniline, toluidine, xylidine or *p*-dodecylaniline derivs.

Dihaloquinizarins (dye intermediates). Edwin C. Buxbaum (to E. I. du Pont de Nemours & Co.). U. S. 2,181,046, Nov. 21. Various details are given for the production of a dichloroquinizarin, m. 249–50°, in which one of the Cl atoms is in the 6- or 7-position, and of a corresponding dibromoquinizarin, m. 225–7°, which by heating with Ac_2O and a trace of H_2SO_4 yields a diacetoxydibromoanthraquinone, m. about 250°.

α-Aminoanthraquinones. Friedrich Felix, Paul Grossmann and Max Bommer (to Soc. pour l'ind. chim. à Bâle). U. S. 2,180,805, Nov. 21. By reactions such as by heating together 1-methylamino-4-(γ-chloro-β-hydroxypropylamino)anthraquinone, acetone, water and Na thiosulfate, α-aminoanthraquinones are produced, of the general formula of an anthraquinone substituted in the 1-position by —NHR and in the 4-position by $—NH_xSSO_3H$ in which R stands for H, alkyl or a six-membered aromatic nucleus, and *x* stands for an alkylene or hydroxyalkylene radical contg. at least 2 and not more than 3 carbon atoms, which products form dark powders which dissolve in water to violet to blue and to green-blue solns. and dye similar tints.

Anthraquinonylaminoanthraquinones. Joseph Deinet (to E. I. du Pont de Nemours & Co.). U. S. 2,181,048, Nov. 21. *Dyes* giving orange-red or red to deep-purple

dyeings are prepd. from 2-halo-6-anthraquinonecarbonyl chloride by condensation with amino compds. of the anthraquinone series including the heterocyclic substituted anthraquinone compds. such as anthrapyridones, anthrapyrimidines and anthraquinonebenzacridones, various examples being given of the production of dyes of the general formula of an anthraquinone substituted in the 6-position by Cl and in the 2-position by the group RHNCO— where R stands for a radical of the anthraquinone series attached to the —N— in an α position.

Anthraquinone compounds containing nitrogen. Soc. pour l'ind. chim. à Bâle. Fr. 841,096, May 10, 1939. A 1-halo-3-acylanthraquinone compd. is condensed with a compd. which contains at least 2 H atoms linked to a N atom, such as NH_3, primary amines and amides, etc., and the product obtained is sapond. The reaction is preferably carried out in a solvent of a high b. p., such as $C_6H_5NO_2$, $C_6H_4Cl_2$, $C_6H_3Cl_3$, etc., and in presence of an agent capable of neutralizing the hydrogen halide. The 1-halo-3-acylanthraquinones are obtained by condensing 1-halo-3-anthraquinonecarboxylic acid halide with an aromatic hydrocarbon in presence of $AlCl_3$. The products, which can be further treated with compds. contg. a reactive halogen atom, are valuable *cotton dyes* and may be used as intermediaries in prepn. of other dyes.

Cerulein derivatives. Eduard Peyer (to Durand & Huguenin A.-G.). U. S. 2,180,769, Nov. 21. See Fr. 836,711 (*C. A.* **33**, 5672[2]).

Dyeing vegetable fibers with insoluble azo dyes. I. G. Farbenind. A.-G. Fr. 840,792, May 3, 1939. See Brit. 498,534 (*C. A.* **33**, 4437[6]).

Dyeing mixed wool and casein fiber. Achille Vandekerckove. Fr. 840,879, May 5, 1939. At low temp there is obtained a fabric partly white and partly colored, because casein fiber has greater affinity for colors than has wool.

Dyeing ethers and esters of cellulose. Soc. pour l'ind. chim. à Bâle. Fr. 841,192, May 12, 1939. Dyes contg. in their mols. at least once the group $-OCH_2CH_2OSO_3H$, dye ethers and esters of cellulose. The operation is effected in the usual dyeing apparatus. Among examples, a tissue of rayon acetate is dyed for ½ hour at 40–80° and then for an hour at 80°, in a bath contg. 1 part of the dye, obtained from diazotized *p*-nitroaniline and the sulfuric ester of 2-amino-4-methylphenyl-β-hydroxyethyl ether, according to Fr. 616,100, as its NH_4 salt, and 30 parts Na_2SO_4 in 1000 parts of water.

Dyeing package yarn. Harry S. Drum, Wm. C. Dodson and Wm. H. Jaxheimer (to Smith, Drum and Co.). U. S. 2,180,896, Nov. 21. App. is described, and a method of operation which involves maintaining yarn packages superposed in a vat and submerged in dye liquor, stopping the supply of dye liquor, circulating water through the packages and into the vat to mix with and displace the dye liquor until the discharge is substantially clear, and then draining the vat.

Coloring organic cellulose derivatives such as cellulose acetate, etc. James G. McNally and Joseph B. Dickey (to Eastman Kodak Co.). U. S. 2,180,012, Nov. 14. Dyeing is effected in orange-yellow or orange-red shades by use of the monoazo dye produced from 1-amino-3-nitro-4-methoxybenzene and dimethylaniline or other dyes of the general formula $\overset{\displaystyle R}{\overset{|}{C}}H{:}C(NO_2).CH{:}CR_1.CH.CN$ where R represents the residue of an acyl coupling component of the benzene series contg. but one benzene nucleus and R_1 represents an alkoxy group. Numerous examples are given.

Wet treatment of raw bast fibers such as those of flax. Helmuth Korte (to I. G. Farbenind. A.-G.). U. S. 2,180,087, Nov. 14. Raw bast fibers are subjected to mech. treatment in a decorticator to remove woody matter from them, and then subjected in the form of roving on cross-wound bobbins to a wet treatment adapted to improve the phys. properties of the fibers, as by use of solns. of HOCl, NaOH and Cl. Cf. *C. A.* **33**, 406[6].

Treatment of artificial fibers, cotton, silk, etc. György Bordás. Hung. 122,659, Jan. 2, 1940. The fibers are treated with a hot soln. of chlorinated lime, NaF and oxalic acid in water, washed, treated with $NaHSO_4$, H_2SO_4 and FeS, washed in soapy water and dried. The dry fibers are then treated in baths contg. Na phosphate, olive oil or wool fat or potassium soap, washed with dil. sulfuric acid and dried.

Making fibrous matter hydrophobic. I. G. Farbenind. A.-G. Fr. 841,087, May 10, 1939. Hydrophobic properties are conferred upon textiles, by treating with an org. compd. contg. a hydrophobic radical and a group capable of forming complex compds., and with a sol. metallic compd. capable of forming complex compds., such as the compds. of Cr and Zr. As org. compds., those contg. a mercapto or a OH group and a carboxyl group linked to the aromatic ring in ortho position, such as salicylic acid and its derivatives, are particularly suitable. The hydrophobic radical is preferably an aliphatic radical contg. at least 10 C atoms, which can be linked to the salicylic acid group. As sol. compds. of Cr and Zr, there are used the salts which give in water a strong acid reaction, such as chlorides, nitrates, etc.

Aftertreatment of rayon yarn. Johann J. Stöckly and Kurt Schmidt (to North American Rayon Corp.). U. S. 2,179,985, Nov. 14. App. is described, and a process for the aftertreatment of yarn such as that formed from viscose which involves only partially filling a compartment of a tank with such spun goods, passing uniformly distributed aftertreating liquid such as water from below through the spun goods, controlling the rate of flow of the treating liquid through the goods so that a uniform distribution of the goods in the tank takes place, and discharging the aftertreating liquid from the upper end of the tank.

Textile finishing. Theodor Rotta and Kurt Quehl, Fr. 841,178, May 12, 1939. A waterproof finish, resistant to washing, is formed on cellulose fiber, without affecting appreciably its inner structure, by treating the textile, either with swelling products at a concentration sufficient to produce a partial swelling effect but insufficient to transform the fiber into transparent polysaccharides, or with substances which, at the temp. of treatment, are incapable of producing more than a limited swelling effect. The increase in the wt. of the fiber by the treatment should not exceed 10–50%.

Finishing textile materials. Harold I. Huey (to Sayles Finishing Plants, Inc.). U. S. 2,179,505, Nov. 14. App. is described, and a process of imparting a silk-like finish to fabrics such as those of cotton which involves impregnating the fabric with a NaOH soln. of 20° Twaddell or greater concn., at room temp., exposing the impregnated fabric while under tension to a dry heat above 93° until substantially dry, and removing the NaOH, as by washing.

Finishing composition for textile materials such as cellulose acetate rayon. Richard R. Sitzler (to Celanese Corp. of America). U. S. 2,180,436, Nov. 21. A finishing compn. is prepd. by a process involving reaction of an alkali bisulfite such as $NaHSO_3$ with more than an equimol. proportion of a cyclic ether such as ethylene oxide (suitably by heating with water).

Textile and leather treatments such as finishing and fat liquoring. Thomas A. Printon (to National Oil Products Co.). U. S. 2,180,256, Nov. 14. Rice oil is used (suitably after being sulfonated and in various mixts.).

Decorating narrow fabrics such as ribbons. Alexander Milhomme (to Progressive Silk Finishing Co.). U. S. 2,180,745, Nov. 21. A process of decorating ribbons and similar narrow fabrics having a relatively heavy weft and a relatively fine warp involves passing the fabric between a pair of scratch rollers to effect a displacement of the weft and then running the fabric through intermeshing rib rollers, the spacing of the ribs being about the same as the spacing of the weft and the ribs running parallel and extending the full width of the weft so that a design is applied uniformly to both sides of the fabric.

Felted fabric suitable for use as a shoe felt, etc. Hugo Boeddinghaus (to American Felt Co.). U. S. 2,181,043, Nov. 21. A mixt. of natural fibrous material such as

wool and stretched thermoplastic fibers such as those of a vinyl resin is formed into a batt, the batt is felted to bond the material and heated to shrink the thermoplastic fibers and effect shrinking of the entire fabric in both directions. An arrangement of app. is described. 1

Automatic weighing appartus for textile materials. Joseph B. Howe (to Geo. S. Harwood & Son). U. S. 2,179,743, Nov. 14. Various structural, mech. and operative details.

Mercerization. Herman A. Bruson and Clinton W. MacMullen (to Röhm & Haas Co.). U. S. 2,176,833, Oct. 17. See Fr. 834,169 (*C. A.* **33**, 3612[1]). 2

Sizing agents. Carl Mascke. Fr. 841,162, May 12, 1939. A nonoxidizable textile sizing agent, sol. in benzine, is obtained by partially sapong. a mixt. of resins and semidrying or nondrying oils. The sapon. is carried out only to a point at which the agent is still sol. in benzine. Several examples are given, among others, 2 parts of colza oil, 8 parts of resin and 1 part of wax are heated with $^1/_{10}$–$^1/_{50}$ of their wt. of borax.

26—PAINTS, VARNISHES AND LACQUERS

A. H. SABIN AND CARLTON H. ROSE

Changes and improvements in paint manufacture seen by the laboratory. C. E. Rogers. *Am. Paint J.* **24**, 24, 26–7(Jan. 22, 1940).—A general discussion emphasizing the improvements in white pigments and some of the newer drying oils, or combinations of oils. W. H. B. 3

Phosphorescent paints. O. Petzold. *Paint Manuf.* **10**, 7–10, 23(1940).—Pigments, dispersing agents, solvents, plasticizers, resins and thickening agents are considered. W. H. Boynton

Notes on the prepn. of luminous paints. Fritz Ohl. *Seifensieder-Ztg.* **67**, 7–8, 27–8(1940).—A review of suitable compns. A. Guillaudeu 4

Aluminum paint as a fire hazard. National Safety First Association. *Bulletin Natl. Safety First Assoc.* **1939**, Jan., 6; June, 47; July, 54; *Rev. Current Lit. Paint, Colour, Varnish & Allied Ind.* **12**, 472(1939).—Al paint on rusty Fe surfaces may sometimes be ignited by striking the hot surface with a steel rod. George Ayers

Paint-mixture control by the viscosity method. E. A. Zahn. *Products Finishing* **4**, No. 2, 30–1, 34–6(1939).—A simplified viscometer, shown diagrammatically, makes it possible to take viscosity readings in as little as 20 sec. The app. consists of a bullet-shaped cup of a capacity of approx. 44 cc. which is suspended on a long looped handle. The cup has an orifice at the bottom through which the material flows when the cup is lifted from the liquid. The time required for complete drainage, beginning when the cup leaves the liquid and ending when the stream breaks at the base, is considered to be the viscosity in sec. The readings taken with this instrument are converted to centipoise readings by a single conversion factor. This instrument can be used to control the viscosity of batches of paints and is very useful in the supervision of mixts. in automatic dipping tanks and other automatic application devices. Leopold Scheflan 5

Paint coatings in place of metal coats. H. F. Sarx. *Angew. Chem.* **52**, 715–17(1939).—A summary. Karl Kammermeyer 6

The analysis of chrome green and similar composite pigments. J. H. van der Meulen. *Chem. Weekblad* **36**, 855–9(1939).—Objections are raised to the methods of Kappelmeier (*C. A.* **25**, 5302; **28**, 3690[7]) and a new procedure is described in detail. The mixt. of $PbCrO_4$, Prussian blue and $PbSO_4$ is decompd. by boiling with Na_2CO_3. Chromate is detd. iodometrically in the filtrate after acidifying with HCl; the oxidation of some of the ferrocyanide by the chromate upon acidifying does not alter the result. To another portion of the filtrate an excess of a soln. of pure $K_4Fe(CN)_6$ is added and the soln. is acidified; the chromate is quantitatively reduced and the excess ferrocyanide is detd. with $KMnO_4$. From the result the amt. of ferrocyanide in the soln. can be calcd. After the chromate in another portion of the filtrate is reduced with H_2O_2, the sulfate can be detd. gravimetrically as $BaSO_4$. T. H. Dunkelberger 7

A method of quickly drying inks. E. L. Duhring, *Printing Review*, Autumn, **1939**, 936; *Rev. Current Lit. Paint, Colour, Varnish & Allied Ind.* **12**, 431(1939).—The first side of the printed web is heated with steam in the Curtis installation. George Ayers 8

A method of quickly drying inks. D. Macgregor. *Printing Review*, Autumn, **1939**, 936; *Rev. Current Lit. Paint, Colour, Varnish & Allied Ind.* **12**, 432(1939).—The disadvantages of ozone for acceleration of drying of inks are discussed. George Ayers 9

Ink and the offset printer. G. W. Whitfield. *Brit. & Colonial Printer* Nov. 2, **1939**, 355; *Rev. Current Lit. Paint, Colour, Varnish & Allied Ind.* **12**, 432(1939).—A discussion of the effect of damping water on litho inks. George Ayers

Specifications for oiticica oil. Charles Holdt. *Am. Paint J.* **23**, 21–2, 46–8(Sept. 25, 1939); cf. *C. A.* **33**, 8045[6]. **Further remarks on oiticica oil.** Otto Eisenschiml and Gerald Eisenschiml. *Ibid.* **24**, 26–7, 58, 60, 62(Feb. 5, 1940).—Polemics. W. H. Boynton

Evaluation of nitrocellulose lacquer solvents. A study of hydrocarbon diluents by the constant-viscosity procedure. V. W. Ware and W. M. Bruner. *Ind. Eng. Chem.* **32**, 78–82(1940); cf. *C. A.* **33**, 9685[8].—The const.-viscosity procedure was applied to BuOAc, iso-BuOAc, iso-Bu propionate and pentaacetate solns. of nitrocellulose, covering the whole range of dilns. with toluene, high-solvency naphtha or ordinary naphtha. With BuOAc and iso-BuOAc, tests were also carried out in the presence of nitrocellulose-resin mixt. (2 1). The value as a diluent decreases in the order, toluene, high-solvency naphtha and ordinary naphtha; this decrease is considerably greater with nitrocellulose-resin mixts. than when nitrocellulose alone composes the entire "solids," especially with dilns. above 20%. BuOAc and iso-BuOAc are similar in solvency characteristics and diluent acceptance, even in the presence of resin. Iso-Bu propionate, which has high solvent strength, is a suitable high-boiling ingredient of nitrocellulose lacquers. George Ayers 10

Reaction of maleic anhydride with abietic acid and rosin. A. G. Hovey and T. S. Hodgins. *Ind. Eng. Chem.* **32**, 272–9(1940).—The literature on the structure of the acids assocd. with rosin and of their addn. products with maleic anhydride (I) is reviewed. Wood rosin (II) and gum rosin (III) behaved identically in their reactions with I at 200°. III gave a product with higher m. p. and lower sapon. no. than II. An old, oxidized sample of II gave a lower sapon. no. and much darker color. These products corresponded with purified prepns. made from abietic acid and I in mol. wt. and compn. but melted much lower. Arnold M. Collins 11

Recovery of thinners in rotogravure. G. Degaast. *Bull. mens. anciens élèves inst. chim. Paris*, Apr., **1939**, 122–31; *Rev. Current Lit. Paint, Colour, Varnish & Allied Ind.* **12**, 431(1939). George Ayers 12

Nitrocellulose lacquers. Fritz Ohl. *Nitrocellulose* **10**, 219–21(1939).—A review. E. M. Symmes 13

Cellulose derivatives in lacquers. C. Maters. *Paint Ind. Mag.* **55**, 15–16, 18–19(1940).—See *C. A.* **34**, 648[3]. W. H. Boynton 14

Protective enamel finishes for magnesium-base alloys. E. E. Halls. *Products Finishing* **4**, No. 3, 42–6(1939).—The crit. feature in enameling Mg alloys is detd. by the fact that Mg is highly electropos., thus rendering enameling and painting difficult and making it necessary to convert the Mg surface to an inert layer by any one of a no. of aq. pretreatment processes, mostly having a chromate base. Tables show the performance of enameled Mg alloys in salt spray atm., in hot and cold humid atm. and 15

under open-weather conditions, as well as the alloy compn. of the test specimen and the characteristics of the primers and enamels used on the test specimen. The results of all types of exposure tests show the benefit to be obtained by the use of chromate pretreatment or a special primer. Extraordinary improvements are obtained by the use of a chromate primer, even without chromate pretreatment, as well as by the use of both a chromate primer and a chromate pretreatment. An appreciable advantage can be obtained by using an ordinary red oxide variety of primer; however, the benefit is not quite so marked as with the Zn chromate type. The data show that satisfactory results are obtainable without departing far from normal com. practice. An aq. chromate pretreatment and a synthetic Zn chromate primer provide the groundwork. Finishing coats may then be cellulose or baking, synthetic, oil, crystal or crinkle. Thus, all types of workpieces can be finished without any deviation from the present finishing procedures. Leopold Scheflan

Manufacture of oilcloth. Felix Fritz. *Nitrocellulose* **10**, 223–6(1939); cf. *C. A.* **33**, 9686[1].—A review. E. M. Symmes

Science Library Bibliographical Series, No. 503, 1939. Luminous Paints, 1920–38. London: Science Museum. 51 references.

Paint and tile base. Frank W. Corkery. U. S. 2,180,729, Nov. 21. A viscous elastic compn. suitable for position for mastic tile which is solid at normal room temp. and having a color intensity below a No. 10 color on the coal-tar resin color scale, consists of a self-compatible oxidized mixt. of an oxidizable drying oil and an oily aromatic substance composed preponderantly of the dimers of coumarone and indene and having by virtue of freedom from any substantial content of polymers in stages of polymerization higher than that of the dimers elasticity in high order and no definite m. p., the material consisting in substantial proportion of its oxidized aromatic initially oily component and being solid at normal room temp.

Stabilizing luminescent colors and paints. I. G. Farbenind. A.-G. Fr. 841,006, May 9, 1939. Addn. of 10–20% of B_2O_3 or of anhyd. Na_2CO_3 to luminescent colors and paints contg. alk. earth sulfides stabilizes the colors and the paints against humidity, without affecting appreciably the intensity of the luminescence. An appropriate binder, such as a polystyrene lacquer, is added to the product. Many examples are given.

Apparatus for mixing paint pigments and vehicles, etc. David A. Wallace. U. S. 2,179,970, Nov. 14. Various details of a mixing and grinding app.

Preparing pigment pastes. Leo Roon and Arthur Minich (to Nuodex Products Co.). U. S. 2,180,721, Nov. 21. An app. with coöperating rolls is described, and a method of speeding up the making of pigment pastes which involves commingling a pigment and an org. liquid vehicle selected from the group consisting of oils, varnishes, resins, and plasticizers, to form a pigment-vehicle system. A grinding aid for conditioning the pigment-vehicle system is added to such system for increased utilization of grinding energy and concurrently expediting distribution of pigment particles in the vehicle. The pigment-vehicle system comprises a soln. of one or more xylene-sol. high mol. wt. org. polymers, selected from the group consisting of natural and synthetic rubber, and one or more wetting agents capable of forming a homogeneous soln. with the polymer constituent, the latter being present in quantities not exceeding 2.5% based on the total wt. of the resulting mass and the grinding aid soln. having a viscosity of not less than 50 centipoises. Thereafter grinding energy is applied to the mass for the purpose of finely subdividing the pigment constituent and distributing the pigment particles uniformly throughout the vehicle.

Modified oils for use in varnishes, nitrocellulose compositions such as lacquers. Laszlo Auer (to J. Randolph Newman, as trustee). U. S. 2,180,342, Nov. 21. Castor oil or various other specified fatty oils are given a thickened body or solidified to produce products sol. in acetone, BuOAc or benzene by heating with various compds. such as NH_4I, Ba thiocyanate, CdI_2, $ZnBr_2$, *p*-cresol or 2,5-dichlorobenzenesulfonic acid, *p*-nitrophenol, etc., (suitably together also with Li_2SO_3 or Li_2CO_3). Numerous details of treatment and of uses of the products are given.

Varnishes having high-paraffin hydrocarbon tolerance. Evart E. Mayfield (to Hercules Powder Co.). U. S. 2,180,535, Nov. 21. A method of making a varnish, contg. a paraffin hydrocarbon-insol. resin derived from pine wood, involves cooking the resin at a temp. of about 295-315° with China wood or linseed oil or other drying or semidrying oil and with a compd. of Zn, Pb, Sn, Mn or Co, such as PbO, etc.

Flat liquid coating composition. Charles G. Harford (to Monsanto Chemical Co.). U. S. 2,180,145, Nov. 14. A film-forming liquid such as a clear varnish has incorporated with it a ground aerogel such as a silica aerogel having in the mixt. substantially the structure of the gel as originally formed.

Chlorinated rubber-cellulose ester compositions suitable for coatings, etc. Heinrich Michaelis, Jr. (to Richard M. Ritter). U. S. 2,179,980, Nov. 14. A process of prepg. a homogeneous, stable and nonsepg. composite product of chlorinated rubber and a cellulose ester such as cellulose acetate or nitrate involves heating the chlorinated rubber to above 100° for a prolonged time with a drying or nondrying oil, plasticizer or oil-modified alkyd resin, to effect sufficient modification, then dissolving the modified chlorinated rubber in one portion of a neutral solvent for it and for the cellulose ester, and dissolving the cellulose ester in another portion of the mutual solvent, and then blending the 2 solns. Various examples are given. Cf. *C. A.* **33**, 3616[4].

Printing materials such as floor coverings. Philip H. Pennell (to Armstrong Cork Co.). U. S. 2,179,562, Nov. 14. App. is described, and a method involving applying a film including an oil such as heat bodied linseed oil and a resinoid such as an amberol mixt. which is but difficultly sol. in the oil, the film having a thixothropic body susceptible to rapid micelle formation when shearing forces cease to be applied, heating the film while in a horizontal position and at rest, and moving the material carrying the film through an inclined path and curing it at a temp. sufficient to effect substantially complete conversion of the resinoid with the oil.

27—FATS, FATTY OILS, WAXES AND SOAPS

E. SCHERUBEL

The fat of the spiny fern. J. Maizīte. *Acta Univ. Latviensis. Kim. Fakultat. Ser.* **4**, No. 14(in Lettish, 529–45; in German, 546)(1939).—In the prepn. of crude filicinic acid from *Aspidium dilatatum*, Mg residues remained from which petr. ether removed 35–39% of a green fat solidifying from 30 to 21°. The fat possessed the consts.: acid no. 0.66, sapon. no. 157.4, esterification no. 156.7, Hehner no. 89.8, Reichert-Meissl no. 8.32, Polenske no. 0.37 and I no. 116.7. The fat contained 14–21% of an unsaponifiable fraction, 7.2% glycerol, 60.5–77.5% water-insol. fraction, and 1.6% of volatile water-sol. acids contg. *n*-BuOH. In the unsaponifiable fraction the phytosterol was 0.59% of which 0.43% was combined and 0.16% remained free; the solid fats approached 5.6%, while the liquid fats consisted of oleic acid contg. 16–21% linoleic acid. Frank Maresh

Fatty acids and glycerides of the fat from the seeds of Garcinia indica (kokum butter). N. L. Vidyarthi and C. J. Dasa Rao. *J. Indian Chem. Soc.* **16**, 437–42 (1939).—The component fat acids were detd. by the Pb salt sepn. and ester fractionation and found to be: myristic 1.2, palmitic 5.3, stearic 52.0, and oleic 41.5%. The component glycerides of the fat were detd. by resolving it into 2 fractions by systematic crystn. from acetone. The amt. of fully satd. glyceride was detd. by successive oxidation of the fat. The glycerides as detd. were: tristearin 2.0, oleodistearin 59.0, dioleostearin 21.0, oleopalmitostearin 14.0, oleodipalmitin 2.0, and palmitodiolein 2% in round nos. E. Scherubel

Fatty acids and glycerides of the oil from sapota seeds (Acharas sapota). N. L. Vidyarthi and M. Venkatesh Mallya. *J. Indian Chem. Soc.* **16**, 443–8(1939).—The seeds of *Acharas sapota*, an evergreen tree of southern India, weigh about 0.5 g. and contain 20% of liquid fat having the following consts. $d_{31°}$ 0.8725, $n_{31°}$ 1.463, sapon. no. 205.4, I no. (Wijs) 59.8, acid no. as percentage of oleic acid 8.94, R. M. no. 2.8, Hehner no. 92.6 and unsaponifiable 1.8%. The component fat acids found were: lauric 1.6, myristic 6.2, palmitic 12.6, stearic 12.0, oleic 66.2, and linoleic 1.4%. The component glycerides were calcd. to be: oleopalmitostearin 5.0, dioleomyristin 23.0, dioleopalmitin 36, dioleostearin 28.0, and trolein 5% with another 3.0% of disatd. monoolein in which probably the satd. acids are lauric, myristic and a little palmitic acid. E. Scherubel

Properties of coconut oil prepared directly from fresh coconut milk. D. M. Birosel, F. Millar, Jr., E. Nessia and F. Tagorda. *Univ. Philippines Nat. and Applied Sci. Bull.* **7**, 39–49(1939).—Coconut oil obtained directly from fresh coconut meat by expressing the milk by roller press, centrifuging and coagulating the proteins, was analyzed for its phys. and chem. properties. Its compn. was detd. by converting the glycerol esters of the oil into fat acids, methylating them and fractionating the Me esters. The sapon. nos. and I nos. of the fractionated Me esters were also detd. The consts. obtained lie within the range given for coconut oils in general. The av. percentages of fat acids from 3 distns. are: caproic 0.38, caprylic 6.54, capric 8.95, lauric 55.06, myristic 16.89, palmitic and stearic 7.36, oleic 4.01, linolic 0.81. Butyric and all other fat acids lower than caproic were not present in detectable amts. in the mixed fat acids of the coconut oil sample. E. Scherubel

The vitamin A and D content of some seal oils. Herman Lövenskiold. *Tids. Kjemi Bergvesen* **19**, 118–19 (1939).—The liver oil contained 1300–10,000 I. U. vitamin A (by ultraviolet absorption) about 10 I. U. per g. vitamin D. The oil from dried seal flesh ("klappmyss") contained 100 I. U. vitamin D per g. H. Kringstad

The use of tall oil for the preparation of textile detergents. Hans J. Henk. *Seifensieder-Ztg.* **67**, 22(1940).—Tall oil, a by-product of sulfite pulp manuf., contains about 50% fat acids and 40% rosin acids. Where the odor of tall oil is permissible, soaps can be prepd. without other fat acids. Such soap can be used to disperse petroleum, paraffin oil, vat dyestuffs, etc. Tall oil soap can be used for the most varied textile requirements, including scouring raw wool, washing white woolens, washing cotton, dyeing, desizing, degumming of silk. Tall oil soap should not be present during Cl bleaching because it is easily oxidized and the odor is increased. In the peroxide bleach, also, tall oil soap increases the consumption of bleach by 50%. The soap is pptd. by hardness in waters. A. Guillaudeu

Cold-process soaps. J. M. Vallance. *Soap* **16**, No. 1, 21–4; No. 2, 30–1, 67(1940).—Various aspects of cold-process soap manuf. are discussed including raw materials, temps., type of frames, oxidation, builders and fillers, perfumes, utilization of scrap and special types of this soap. E. Scherubel

Soap stabilization. R. L. Sibley. *Soap* **16**, No. 2, 21–2(1940).—Rancidity tests were made by incorporating 0.1% of 43 different antioxidants in a neutral soap made from 3 parts edible tallow and 1 part coconut oil; and 5 g. of the treated soap were then placed in a 250-cc. glass-stoppered flask, and a piece of filter paper satd. with H_2O was torn into small pieces and added to the soap. The tightly stoppered flask was kept at a const. temp. of 50° in an oven. The color and odor were noted daily and compared with a control. All of the antioxidants tried were thioureas and all were superior to thiourea itself in respect to antioxidant properties. In general aryl substituted thioureas are superior to the alkyl substituted thioureas. Cottonseed oil to which thioureas were added was subjected to Wheeler's peroxide test. It was found that the thioureas as a class are effective in delaying rancidity, yet, the order of effectiveness does not appear to be of the same degree as that shown in the organoleptic test. In general thioureas protect soap against deterioration resulting from oxidation and further stabilize the soap against discoloration in light. E. Scherubel

28—SUGAR, STARCH AND GUMS

J. K. DALE

Estimation of optically active nonsugars and application to (beet) distillery juices. Ippolito Sorgato. *Ind. saccar. ital.* **32**, 535-8(1939).—Control calcns. should be based on total reducing sugars rather than on sucrose or loss of polarization. For this purpose it is necessary to take account of optically active nonsugars, which are estd. from the polarization and the detn. of invert sugar before and after total inversion. Only in this way is it possible to keep track of losses by fermentation in the diffusion or increases in polarization due to inversion of sucrose in the preparative operations. O. W. Willcox 2

Biochemical and anatomic characteristics of starch. I. A. Veselovskiĭ. *Khlopchato-Bumazhnaya Prom.* **1939**, No. 5, 45-6.—Biochem. analysis of pure starch obtained from various types of potatoes indicates that the ash content, viscosity (η), and P are definitely related, the η increasing with increasing ash and P. For P content ranging from 0.063 to 0.124% and ash from 0.147 to 0.361% the η ranged from 4.1 to 14.1% (for 0.3% starch soln. referred to water). The larger the grains of starch the easier it is hydrolyzed with acid. Fibers sized with various starches were tested for strength and those treated with starch from the potato were the strongest. B. App. is described, and a process which involves dropping starch particles such as raw starch from a centrifugal app. through a hot gas (such as air heated to 300°) flowing countercurrent to the starch.

29—LEATHER AND GLUE

HENRY B. MERRILL

The precipitation of natural tanning agents with calcium hydroxide. Vladimír Němec. *Tech. Hlídka Koželužská* **15**, 80-1, 83-5(1939)(German summary). The usual pptn. of tanning agents with lime water pptd. the agents but left a soln. too dil. for analyses. N. pptd. the tanning agents with powd. CaO. In an Erlenmeyer flask treat 50 cc. of the tanning ext. with 2 g. of powd. CaO, attach a reflux air condenser, heat for 5 min., cool and filter through a Schleicher-Schüll blue label 11-cm. filter. Place 25 cc. of the filtrate in a quartz or Pt dish, evap. to const. wt., and ash the residue in an elec. oven. In exts. of quebracho, chestnut, pine, oak, mangrove, mimosa and sumach barks all natural tanning agents were pptd. by the powd. CaO. When the tanning agents were in the form of condensed compds. the fraction which was not pptd. by the CaO corresponded quantitatively to the fraction of nontanning agents; the size of this fraction was independent of the sugar content of the ext. When the tanning agents were in the form of hydrolyzable products, the CaO pptd. some of the nontanning agents, principally monosaccharides which detach themselves from their org. structure and combine with the CaO to form an insol. substance. Filtrates contg. agents in the form of condensed compds. were red or brown in color; those filtrates contg. the agents in the form of hydrolyzable products were pale yellow or colorless. The brief heating of the exts. under the condenser prevented some of the oxidations which occur at room temp. The evapn. in a Pt evapg. dish was more rapid than that occurring in a quartz dish. Theory of mineral tannage (summary). Egon Elöd and Theodor Schachowskoy. *Kolloid Beihefte* **51**, 1-122 (1939); cf. *C. A.* **31**, 7692[3].—Data previously presented are reviewed. The following conclusions are drawn: (1) Previously employed exptl. methods are inadequate to decide which of the several theories, advanced to explain the facts of chrome tanning, is the correct one. (2) From examn. of gelatin films treated with mineral tanning agents under comparable conditions, it is concluded: (*a*) many materials previously described as tanning agents really have no influence on the soly. of gelatin; (*b*) each tanning agent is most effective in a characteristic pH range, which is related to the pH value at which the hydroxide or basic salt is pptd.; (*c*) Cr sulfate is more effective than the nitrate or chloride; (*d*) the quantity of Cr salt required for a given tanning effect declines slowly with increasing basicity and particle size up to basicity = 60 to 70% and av. mol. wt. = 4000, above which the rate of decrease is very rapid. (3) From absorption spectra of solns. of Cr^{III} and Co^{III} salts, with and without gelatin, it is concluded that combination between these metals and gelatin occurs neither by primary valence union nor by addn. of unaltered metal complexes to the gelatin, but rather by formation of mol. compds. of highly basic metal salts with gelatin. (4) The combination of Cr salts with gelatin is not comparable to the combination of Cr salts with glycine. (5) Detanning expts. show that a small part of the Cr is fixed much more tenaciously than most of the tanning agent, perhaps because of combination with several micelles. (6) It is impossible from present data to det. with which protein groups the Cr combines. From x-ray evidence, a regular, crystal-like distribution of Cr throughout the collagen micelle seems improbable. (7) Cr nitrate and chloride, as well as the sulfate, can produce leather that withstands the boil test. The importance of shrinkage temp. as a criterion of tannage is perhaps overestd., since untanned skin withstands boiling at certain pH values (12.5 to 13.0). (8) If mineral tanning does not consist of primary valence combination, then other lyophilic col-

loids should be capable of being tanned. This was confirmed with polyvinyl alcs. H. B. Merrill

Flora of tan liquors. P. Chambard and M. Seux. *J. Intern. Soc. Leather Trades Chem.* **23**, 542–9(1939)(in French).—The role of mycoderma yeasts in vegetable tan liquors has received little study. Three species (I) an unidentified mycoderma, (II) an unidentified torula and (III) a monilia (*M. variabilis*) were isolated from com. tan liquor, and grown in sucrose-malt peptone (or dry malt) medium. When the sucrose was replaced by pure gallotannin, growth of I and II was inhibited, and III was retarded. Addn. of glucose (10%) permitted growth of all 3 organisms in concns. of tannin up to 8% (scanty above 4%). Analyses showed that no tannin was destroyed by I and II, indicating that these organisms cannot utilize polygalloyl glucose. In the absence of glucose, III destroyed about 10% of the total tannin present in 2% tannin soln. in 15 days; the percentage destroyed decreased with increasing tannin concn., and increased markedly when glucose was added. Regardless of the initial pH value, fermentations by I, II and III resulted in final pH values of 3.1–3.2, 2.6 and 2.9–3.0, resp. Both volatile and nonvolatile acids were produced. AcOH and AcOOEt were identified by odor. Conclusion: Of the 3 yeasts studied, only the monilia can split gallotannin, but all produce notable amts. of acid by fermentation of sugars in the presence of moderate concns. of tannin. H. B. Merrill

Germproofing of leather. Fred O'Flaherty. *Hide & Leather* **98**, No. 20, 24–6(1939).—Several standard tannery processes have incidental disinfecting action (liming, pickling, Cr and HCHO tannage). Usually a disinfectant is added at one or more stages to inhibit mold growth. Recently a demand has arisen for leather that will not support the growth of skin-disease organisms, especially athlete's foot. Phenol-Hg compds. are effective in very high dilns. The possibility of causing dermatitis in hypersensitive individuals must always be considered. H. B. Merrill

Evaluating the germproofness of leathers. Fred O'Flaherty. *Hide & Leather* **99**, No. 2, 23–6(1940); cf. preceding abstr.—The evaluation is complicated by the variety of germ life encountered and the marked influence upon the effectiveness of any germproofing agent of the conditions under which it is applied. The phenol coeff. obtained with one organism under a given set of conditions has no significance for any other organism or for a different set of conditions. Germproofness of leather can be evaluated by placing a sample on Sabouroud's medium inoculated with the organism under test, usually a mold. Germproofness is indicated by a mold-free halo surrounding the sample after incubation. With a fungicide, this halo may contain colonies of bacteria, since one antiseptic is seldom effective against both molds and bacteria. Leather is not a good medium for the growth of the *Trichophyton* organism responsible for athlete's foot, since this organism grows best at pH values just under 7, while the aq. exts. of most leathers have pH values from 3 to 5. To test the effect of leather on the athlete's foot organism, the leather is moistened with perspiration, inoculated with *Trichophyton*, incubated 24 hrs. at high humidity, and a transfer made from the leather to Sabouroud's medium. Lack of growth of *Trichophyton* on the medium indicates that the leather has killed the organism. H. B. M.

Unhairing skins. Mihály Krasznay. Hung. 122,490, Dec. 15, 1939. Water-sol. alkali or NH_4 salts of org. or inorg. acids are used at a controlled pH value. Na_2S and alkali-resistant emulsifying or dispersing substances also are added.

Treating hides and skins for depilating and bating. Otto Röhm. U. S. 2,179,899, Nov. 14. In a process which includes treating hides or skins in aq. soln. with (1) at least one oxidizing agent selected from a group consisting of alkali nitrates, alkali nitrites, alkali percarbonates, alkali peroxides and hydrogen peroxide, (2) a reducing agent comprising an O-contg. S compd. and (3) a depilating and bating agent comprising a mold tryptase; the treatment with the depilating and bating agent comprises a sep. step from the treatment with the oxidizing and reducing agents.

Apparatus for treating animal skins with liquids such as dyes and "dopes." Louis J. Strobino. U. S. 2,180,562, Nov. 21. Various structural and operative details are described of an app. having a support such as a rotatable drum with a convex surface covered with fibrous material such as plush which may hold a treating liquid among its fibers.

Condensation products having a tanning action. Hermann Schütte (to I. G. Farbenind. A.-G.). U. S. 2,179,800, Nov. 14. A dihydroxydiphenylsulfone is treated, at a temp. of 100–160°, with glycolic acid, in the presence of a sulfonating agent such as concd. H_2SO_4.

Water-soluble condensation products containing phosphorus and suitable for preparing tanning or disinfecting compositions, etc. Josef Schäfer (to J. R. Geigy A.-G.). U. S. 2,180,260, Nov. 14. A process for the manuf. of water-sol. condensation products contg. P involves condensing a mixt. of 1 mol. of a sulfonic acid of a monohydric phenolic compd. of the benzene series and at least $1/2$ mol. of an unsulfonated monohydric phenolic compd. of the same class with at least one of the group consisting of P halides and P oxyhalides at temps. over 120° and neutralizing.

Compositions suitable for softening leather, paper and

textile materials. Luther B. Arnold, Jr. (to E. I. du Pont de Nemours & Co.). U. S. 2,180,133, Nov. 14. A softening agent is prepd. by treating a mixt. of a substantially satd. higher aliphatic petroleum hydrocarbon material such as petrolatum, and a long-chain aliphatic alc. having 12–20 C atoms with a quantity of a sulfating agent such as H_2SO_4 or chlorosulfonic acid, which is not greater than that required for complete sulfation of the alc. in the mixt. under relatively mild conditions (suitably at 55–65°) to avoid the condensation of the components of the mixt.

30—RUBBER AND ALLIED SUBSTANCES

C. C. DAVIS

Molecular weight of sol and gel in crude Hevea rubber. A. R. Kemp and H. Peters. *J. Phys. Chem.* **43**, 1063–82 (1939); cf. *C. A.* **33**, 9712[2].—The instability of high-mol. rubber in tetralin and the difficulty of dispersing rubber gel in C_6H_6 make these objectionable as solvents for detg. the av. mol. wt. of crude rubber. On the contrary, hexane is an excellent solvent for fractionating sols from crude rubber and for viscosity mol. wt. detns. Crude rubber was extd. with *n*-hexane and the mol. wt. of the sol rubber was calcd. from the viscosity of the soln. The Staudinger formula for mol. wt., $M = \eta_{sp}/C\,3 \times 10^{-4}$ (where C is the base molal concn., i. e., 1 mole is taken as 68 g. per l. of C_5H_8) is dependent to a greater extent on the concn. than the Arrhenius equation, $M' = \log_{10}\eta_r\,10^4/C$. The av. mol. wt. detd. by the viscosity method is of questionable value because of the insol. gel present. The mol. wt. distribution of polyprenes in crude rubber depends on the proportion of sol and gel present and these vary widely. The soly. and diffusion rate of sol into hexane from crepe rubber decrease as the mol. wt. of the rubber increases. Sol rubber of a mol. wt. of 210,000 is practically insol. and diffuses very slowly into hexane. The av. mol. wts. of sol rubber fractions from unmilled crepe rubber vary from about 60,000 to 210,000. Milling results in oxidative breakdown of rubber hydrocarbon macromols. to a smaller but more uniform size. Hot milling results in higher av. mol. wts., with a different distribution from that by cold milling. A polar solvent such as abs. EtOH reduces the viscosity of rubber in hexane. The addn. of alc. or Me_2CO to hexane peptizes gel rubber, probably because of a reduction of assocn. or van der Waals forces between the long-chain mols. The peptized gel can be converted to hexane-insol. gel by removing the peptizing agent. Swelling of rubber in an org. solvent depends on the nature of the gel present; a gel that has been peptized swelled much more in hexane when the peptizing agent has been removed. S. I. Aronovsky

Rubber compositions. Fritz Rostler and Vilma Mehner (to Naftolen-Ges. zur Verwertung der Rostler-Mehner'schen Verfahren m. b. H.). U. S. 2,180,367, Nov. 21. A mixt. suitable for use in the manuf. of products such as sheets or tubes comprises rubber together with hydrocarbons of the general formula $(C_5H_4)_n$ of viscous character and high mol. wt. and compatible with rubber in all proportions, sol. in H_2SO_4, highly reactive with S and present in the mixt. to the extent of 5% to 100% the amt. of the rubber for co-vulcanization with the rubber. Various mixts. are described.

Rubber composition suitable for shoe soles, etc. Frederick J. Maywald and Frederick J. Maywald, Jr. (to Maywald-Fleming Patents Co.). U. S. 2,180,906, Nov. 21. Fibers such as those of wool of substantially greater length than 0.1875 in. are milled into rubber with an amount of oily lubricant such as petrolatum, sufficient to render the fibers slippery and in excess of the amt. of oily material added as softeners to rubber, to facilitate even distribution of the fibers without breaking them.

Inhibiting deterioration of rubber. Raymond F. Dunbrook (to Firestone Tire & Rubber Co.). U. S. 2,180,936, Nov. 21. Rubber is mixed with a small proportion of a reaction product of a terpene hydrocarbon such as α-pinene with a secondary aryl amine such as diphenylamine or of a reaction product of a hydroxy deriv. of a terpene hydrocarbon such as terpineol with a primary or secondary aryl amine such as aniline.

Preserving rubber. Samuel G. Burroughs (to Pennsylvania Coal Products Co.). U. S. 2,176,881, Oct. 24. For preventing oxidation and discoloration of rubber there is incorporated with it about 2% of a tetramethylhydroxyspirobiindan in which the methyl groups are attached to the satd. rings and the hydroxy groups to the aromatic rings, such as 3,3,3',3'-tetramethyl-5,6,5',6'-tetrahydroxy-1,1'-spirobiindan. U. S. 2,176,882 (Charles H. Fisher, inventor; to same assignee) relates to a like use of an alkylhydroxyspirobiindan having at least 2 hydroxy groups and different alkyl radicals, such as 2,3,3'-trimethyl-3,3'-diethyl-5,6,5',6'-tetrahydroxy-1,1'-spirobiindan.

Preserving rubber. Albert M. Clifford (to Wingfoot Corp.). U. S. 2,180,666, Nov. 21. Rubber is mixed with an antioxidant which may be produced by reaction of a primary aromatic amine such as aniline or α-naphthylamine with an equimol. proportion of a satd. monohydric aliphatic hydrocarbon alc. such as MeOH, BuOH or iso-PrOH at a temp. of about 275–300° for 7–15 hrs., in the presence of a catalyst such as $ZnCl_2$ or $SnCl_4$.

Preservation of rubber. Joseph R. Ingram (to Monsanto Chemical Co.). Can. 386,493, Jan. 23, 1940. Rubber is treated with an aryloxy substituted diarylamine, e. g., 4-*p*-cresoxyphenyl-β-naphthylamine.

Apparatus for calendering sheet rubber. Paul Gleissner. U. S. 2,180,046, Nov. 14. Various structural, mech. and operative details.

Cellular rubber products. Albert N. Ward and Frank

T. Purkis (to Dunlop Rubber Co. Ltd.). U. S. 2,180,725, Nov. 21. Products are formed from foamed aq. dispersions of latexes contg. a bivalent oxide such as ZnO and with addn. of an aq. soln. of NH_4 salts such as the sulfate, nitrate or acetate normally having a pH less than 7 but conditioned, by adding alk. reagents, to have a pH greater than 7.

Sheet material for separating tacky rubber. George W. Coggeshall (to S. D. Warren Co.). Can. 386,086, Jan. 2, 1940. For carrying, sepg. and protecting tacky rubber during milling and for curing operations, a strong flexible fibrous sheet material, thickness not less than 0.004 in., having smoothed surfaces filled with an org. adhesive, and a bursting strength (Mullens test) of at least 100 lb., is coated with a lacquer compn., at least 0.007 lb. per sq. yd. on each side, contg. as a major proportion of the solid content a fiber-forming substance selected from the group consisting of plasticized org. esters of cellulose, plasticized cellulose ethers, vinyl resins and acryl resins. Cf. *C. A.* **34**, 908[3].

Deodorizing rubber products. Lester S. Cooper (to Rubatex Products, Inc.). U. S. 2,179,494, Nov. 14. A process of producing a deodorized gas-expanded sealed cell rubber structure involves mixing S with rubber and blending the mixt. with a deodorizing material such as Pb carbonate adapted to react with the S and the H_2S that is subsequently formed during the expansion of the rubber mix, regulating the consistency of the rubber mix so that it will entrap gas and retain it, gassing the rubber mix, and heating it to effect at least a 6-fold expansion with deodorizing reactions, and setting the expanded rubber in vulcanized condition.

Rubber mills, etc., with coöperating rolls. Carl F. Schmuck (to Farrel-Birmingham Co.). U. S. 2,179,961, Nov. 14. Various structural and mech. details.

Diaryldithiocarbamyl derivatives (rubber-vulcanization accelerators). Paul C. Jones (to B. F. Goodrich Co.). U. S. 2,177,547, Oct. 24. By the reaction of approx. equimol. quantities of an alkali metal salt of a diaryldithiocarbamic acid, such as Na diphenyldithiocarbamate, and an NH_4 halide such as NH_4Cl with at least an equimol. quantity of CH_2O (suitably with heating to 50°), a product is obtained such as tris(diphenylthiocarbamylmercaptomethyl)amine.

Electrically heated device for vulcanizing tires, tubes, etc. Albert Hoving. U. S. 2,179,819, Nov. 14. Various structural, elec. and operative details.

Rubber vulcanization. Paul C. Jones (to B. F. Goodrich Co.). U. S. 2,177,548, Oct. 24. As vulcanization accelerators, use is made of tris(diphenylthiocarbamylmercaptomethyl)amine and various compds. of the general formula $(RSA)_3N$ in which R represents an org. radical with the free valence on a C atom and A represents an alkylene group.

Hard expanded rubber products Dudley Roberts and Lester S. Cooper (to Rubatex Products, Inc.). U. S. 2,176,946, Oct. 24. Products such as elec. insulators, etc., are formed of a hard and rigid gas-expanded rubber contg. a multiplicity of small sealed cells of gas and contg. a substantial amt. of hard rubber dust, the material having a d. of about 20–40 lb. per cu. ft.

Closed cell expanded rubber material. Geoffrey P. Denton (to Rubatex Products, Inc.). U. S. reissue 21,245, Oct. 24. A reissue of original patent No. 1,905,269 (*C. A.* **27**, 3638).

Thread comprising a plurality of rubber filaments. Wm. M. Spencer (to Filatex Corp.). U. S. 2,177,538, Oct. 24. Various mfg. and structural details of a composite compressible thread.

Rubber floor tile. Albert C. Fischer. U. S. 2,176,068, Oct. 17. Tile of soft rubber floor tile material is surrounded with an edging of rubber film of the same compn., vulcanized to a greater hardness than the rest of the tile.

Carbamyl dithiocarbamates (rubber vulcanization accelerators). Ira Williams (to E. I. du Pont de Nemours & Co.). U. S. 2,171,420, Aug. 29. Compds. of the general formula RANCOSCSNBB wherein R represents an aromatic radical free of substituents other than hydrocarbon, hydroxyl, alkoxy and halogen radicals, A represents a neutral aliphatic radical and B,B together represent two separate and distinct aliphatic hydrocarbon radicals or a pentamethylene radical having two separate and distinct carbon atoms bonded to the N are prepd. by a process which comprises adding about one mol. proportion of an arylalkylcarbamyl halide to a salt of a dialkyldithiocarbamic acid in an inert volatile solvent and sepg. the arylalkylcarbamyl dialkyldithiocarbamate from the solvent. Various details and examples are given of the production of compds. such as: phenylmethylcarbamyl dimethyldithiocarbamate, m. 135–7°; phenylmethylcarbamyl pentamethylenedithiocarbamate, m. 99–101°; phenylethylcarbamyl dimethyldithiocarbamate, m. 89.5-90.5°; phenylethylcarbamyl pentamethylenedithiocarbamate, m. 99–100°; ethyl-*o*-tolylcarbamyl dimethyldithiocarbamate, m. 84–7°; ethyl-*o*-tolylcarbamyl pentamethylenedithiocarbamate, m. 93–5°; β-hydroxyethylphenylcarbamyl dimethyldithiocarbamate, m. 142–3°; *p*-methylbenzylphenylcarbamyl dimethyldithiocarbamate, m. 118–19°; ethyl-α-naphthylcarbamyl dimethyldithiocarbamate, m. 107–9°; ethyl-α-naphthylcarbamyl pentamethylenedithiocarbamate, m. 138.5–40°; methyl-4-hydroxyphenylcarbamyl dimethyldithiocarbamate, m. 136-8°; and methylphenylcarbamyl dicyclohexyldithiocarbamate, m. 102-4°. U. S. 2,171,421 relates to the use of such compds. as *rubber vulcanization accelerators*.

Rubber vulcanization. Lorin B. Sebrell and Albert M. Clifford (to Wingfoot Corp.). U. S. 2,173,732, Sept. 19. As accelerators, use is made of a benzothiazyl ester of butyldithiocarbamic acid or other compds. of the general formula $S.R_1.N:CSC(:S)NHR$ in which R_1 is arylene and $-SC(:S)NHR$ is the residue of a dithiocarbamic acid derived from a primary amine. Cf. *C. A.* **34**, 907[3].

Preserving rubber. Wm. P. Ter Horst (to Wingfoot Corp.). U. S. 2,178,545, Nov. 7. Vulcanization is effected in the presence of (suitably about 1% of) a reaction product consisting of about one mol. of an aromatic hydroxy compd. such as β-naphthol, 5 mols. of CH_2O and 2 mols. of NH_4HS.

Extruding apparatus for making rubber threads or filaments. Max Draemann. U. S. 2,178,955, Nov. 7. Various structural, mech. and operative details.

Re-elasticizing rubber threads associated with a reaction product of glue and formaldehyde. Thomas L. Shepherd. U. S. 2,178,498, Oct. 31. A fabric contg. threads which comprise rubber with which glue has been incorporated to render the threads relatively inextensible and in which the glue has been rendered insol. by treatment of the threads with CH_2O is further treated with an aq. soln. of urea (suitably in 10% aq. soln.) by which the glue content of the thread is rendered sol. and the rubber threads are rendered elastic. Cf. *C. A.* **33**, 6652[3].

Solid rubber products. Henry H. Harkins (to Dominion Rubber Co., Ltd.). Can. 385,213, Nov. 21, 1939. To prevent premature hardening or embrittlement in a solid rubber stock contg. filling, vulcanizing and hardening ingredients including a partially polymerized phenolic resin, the mass is quickly cooled directly after the processing operation and the cooled stock heated to harden the resinous body and cure the rubber.

Rubber tires. Thomas H. Ainlay (to B. F. Goodrich Co.). Can. 385,795, Dec. 19, 1939. There is imbedded in uncured rubber a cord fabric of cotton warp and cellulose acetate weft impregnated with a substance that dissolves cellulose acetate at the vulcanizing temp., and the rubber is vulcanized.

Pneumatic tire casing of vulcanized rubber having cords embedded in it. Herman T. Kraft (to General Tire & Rubber Co.). U. S. 2,179,374, Nov. 7. Various structural and mfg. details.

Side-drive belts, etc., of rubber and fibrous material. Pierre A. Cady (to Raybestos-Manhattan, Inc.). U. S. 2,178,558, Nov. 7. A belt having a reinforced end structure adapted to be engaged by connecting devices such as bolts or pins is formed with a core having a plurality of plies of fibrous material such as textile fabric and rubber,

the number of plies of fibrous material being increased adjacent the ends of the belt.

Molding condensation products of rubber. Herbert A. Endres (to Wingfoot Corp.). U. S. 2,178,537, Nov. 7. Products such as dishes, etc., are formed with heat and pressure in a mold from a substantially unoxidized condensation deriv. of rubber obtained by decompg. with water the reaction product of chlorostannic acid and a rubber cement. Products thus derived and formed may be dipped in Cl water to make them more resistant to oil and grease.

Rubber antioxidants. Albert M. Clifford (to Wingfoot Corp.). U. S. 2,178,536, Nov. 7. Rubber is vulcanized in the presence of (suitably about 1% of) the product derived by the reaction, in one step and suitably in the presence of HCl, of an aldehyde such as CH_2O, a diaryl amine such as *N,N'*-diphenyl-*p*-phenylenediamine and a phenolic compd. such as β-naphthol. Such products serve as "age resisters."

Vulcanization accelerator. Charles O. Miserentino (to Dunlop Tire and Rubber Corp.). Can. 385,087, Nov. 14, 1939. A monobasic org. acid is treated with a secondary amine, and the reaction product treated with CS_2. Cf. *C. A.* **33**, 4462[9].

Shaping and vulcanizing rubber belting, etc. John M. Bierer (to Boston Woven Hose & Rubber Co.). U. S. 2,179,443-4, Nov. 7. Various details of app. and opera-

CHEMICAL ABSTRACTS

Vol. 34 APRIL 10, 1940 No. 7

I—APPARATUS, PLANT EQUIPMENT AND UNIT OPERATIONS

W. L. BADGER

Gorokhov laboratory extraction apparatus. M. Bauman, A. Barbarash and N. Pil. *Maslobοino Zhirovoe Delo* 15, No. 4, 25–7(1939).—Construction and operation details and diagrams are given. Chas. Blanc

New problems of distillation. Molecular distillation. M. Furter. *Mitt. Lebensm. Hyg.* 30, 200–16(1939).—The principles involved in ordinary, vacuum and mol. distn. are discussed. W. J. Peterson

Distillation and rectification with steam. K. Thormann. *Chem. Fabrik* 1940, 3–9.—Advantages of steam distn. are mentioned, followed by a math. discussion of pressure relations, heat and material exchanges, quant. ratios, condensation and rectification, with 9 phase diagrams. J. H. Moore

Design for distilled water. Auburn A. Ross. *Chem. & Met. Eng.* 47, 100–1(1940).—App. in a plant of Eli Lilly and Co. for producing and delivering to the manufg. equipment distd. water of U. S. P. quality is described. The capacity is 100 gal. per hr. E. H.

Automatic evaporation balance. Léon Gros. *Ann. chim. anal. chim. appl.* 22, 9–10(1940).—With the app. described, as much as 1250 ml. of water can be evapd. within 24 hrs. without supervision. It is recommended for the detn. of total solids in water. The dish in which the residue is to be weighed is placed on the balance and under this is a small gas flame. If, at any time with fresh liquid constantly flowing the evapn. is too rapid, the counterpoised arm of the balance drops and thereby the supply of gas to the burner is reduced. Under normal conditions, the introduction of water into the dish takes place at the same rate at which there is evapn. At the end, the contents of the dish are dried in a drying oven at 100°. W. T. H.

The sedimentation balance for measurement of size-distribution of fine materials. Fred C. Bond. *Am. Inst. Mining Met. Engrs., Tech. Pub.* No. 1129, 11 pp. (1939). Alden H. Emery

A new apparatus for determining chemical attack on glasses. Masao Nagaoka. *Glastech. Ber.* 17, 327–9 (1939).—The app. of glass construction is adapted to the powder method of detg. soly. A quartz tube holds the reagent and fits into a compartment, which is jacketed and fitted with a boiling flask and condenser to maintain const. temp. The Pt gauze basket carrying the sample is suspended from an eccentric to furnish adequate stirring. This arrangement permits detn. of wt. loss, alky., also elec. cond. Weight loss seems to be the most suitable measure of chem. attack. A treatment of 48 hrs. gives satisfactory results. J. F. Hyde

A new electrical proportioner. Arthur Kuntze and Karl Branditz. *Chem. Fabrik* 1940, 34.—The app. is for regulating mixts. of gases or liquids. A diagram of connections is shown. J. H. Moore

Scientific principles in the construction of pressure and steam boilers. E. Siebel. *Chem. Fabrik* 1940, 25–30.—Math. and descriptive, with 17 cuts and graphs. J. H. Moore

Concentration by flotation of nonmetallic minerals. H. Vigneron. *Génie civil* 115, 467–9(1939).—A review. Flotation methods have a wide application in the chem. industry as well as in the phys. treatment of minerals. Ann Nicholson Hird

An emulsifier. R. Cluzan. *Bull. trav. soc. pharm. Bordeaux* 77, 216–20(1939).—The app. which is described and illustrated turns out opaque emulsions contg. particles small enough to show Brownian movement. S. W. G.

Two constant-pressure devices. Archibald Clow and Geo. Shand. *J. Sci. Instruments* 16, 354–5(1939).—The manostats, 1 all glass, the other with a Hg regulating valve, are described in considerable detail with 3 cuts. When provision is made for variations in atm. pressure they are capable of maintaining a system of quite small vol. within 0.1 mm. of the desired pressure without any mech. attention. J. H. Moore

Photoelectric control apparatus in chemical industries. W. Jackel. *Chem. App.* 27, 1–2(1940).—A review of recent developments. G. W. Stroebe

Flow of gas-liquid mixtures through consolidated sand. Holbrook G. Botset. *Am. Inst. Mining Met. Engrs., Tech. Pub.* No. 1111, 13 pp.(1939). A. H. E.

Liquefied hydrochloric acid. J. H. Frydlender. *Rev. prod. chim.* 43, 1–4(1940).—A review of manuf. and uses. E. H.

A new instrument for the magnetic determination of carbon in a steel bath. H. K. Work and H. T. Clark. *Am. Inst. Mining Met. Engrs., Tech. Pub.* No. 1132, 11 pp.(1939).—The Carbanalyzer has been shown by exhaustive tests to be sufficiently accurate to fill a need of the industry. It is relatively inexpensive, requires little upkeep, and can be used by a furnace melter. Accuracy on single samples is good while the av. of 3 or more taken in rapid succession is highly accurate. It is a special form of permeameter. Alden H. Emery

The absorption of sulfur dioxide in water. L. C. Jenness and J. G. L. Caulfield. *Paper Trade J.* 109, No. 26, 37–41(1939).—Coeffs. of absorption of SO_2 in H_2O were detd. in a tower packed with 1-in. Raschig rings, covering an approx. range of liquor velocities from 0.09 to 0.69 ft. per min., with gas velocities of 0.037–0.30 ft. per sec. At fixed liquor velocity, the coeff. varies as a power function of the gas velocity, the exponent occurring at higher gas velocities; at fixed gas velocity the coeff. varies as a power function of the liquor velocity, with higher values of the exponent of the gas velocity increasing at higher gas velocities. Resistance to absorption is appreciable in the liquid film at low liquid velocities, but shifts to the gas film at high liquid velocities. A. Papineau-Couture

An apparatus for preventing losses of I_2O_5 in analysis for carbon monoxide. I. N. Ozhiganov. *Lab. Prakt.* (U. S. S. R.) 14, No. 9–10, 21–2(1939).—A thick-wall glass tube (inner diam. 9 mm.) contains a hollow cylinder sealed at both ends, which moves freely in the tube. The upper cone-shaped end of the cylinder is ground to fit the inner wall of the glass tube. The app. is attached after the container of air to be examd. A flow of water forces the air out of the container, the water passes into the app., raises the inner cylinder in the tube and stops the flow of water by pressing the cone-shaped end of the cylinder against the inner wall of the tube. This app. prevents losses of I_2O_5. W. R. Henn

Chlorine compressors. L. A. Smirnov. *Khim. Mashinostroenie* 1938, No. 4, 26–30; *Khim. Referat. Zhur.* 2, No. 4, 139–40(1939).—Cl is liquefied by compression under 15–18 atm. and cooling with water. Details of construction are described and advantages and disadvantages shown of the Amag-Gilpert, Skoda and Krebs machines for the production of liquid Cl. W. R. Henn

An electronic flow meter. Joseph M. Weinberger. *Electronics* 13, 30–1(1940).—An automatic recording device for the flow of water or other liquids through pipes. The vertical gage glass tube contains an opaque liquid. As this liquid rises in the tube, it intercepts a beam of light focussed on a photoelec. cell. This cell is connected through a linear d.-c. amplifier to a recording voltmeter. The use of a photocell provides a practically frictionless and inertialess means of measurement with none of the attendant losses inherent in mech. app. The threshold of operation is much lower than in any mech. system. Details of construction are given. C. G. F.

Grinding-rate curve of the Yentai aluminous shale in a porcelain-ball mill. Masayosi Wada. *Suiyokwai-Shi* 10, 73–8(1939).—Aluminous shale from the Yentai coal field was ground in a porcelain-ball mill. The rate of grinding was expressed by the formula $\omega = Kt^M$ where ω is the cumulative percentage weight of the −0.15-mm. products, t is the cumulative time of grinding in min., K and M are consts. A certain relation exists between the diam. of balls d, and K and M, and if log K is plotted against $1/d$ or log $(1 - M)/M$ against log d, a straight line is obtained. Hideo Nishimura

Gallons in any standard pipe. W. F. Schaphorst. *News Ed. (Am. Chem. Soc.)* 18, 109(1940).—Scales are given showing standard pipe size, length of pipe line, and total gallons in pipe, with the solution of illustrative problems employing this nomograph. W. C. Ebaugh

Pendulum sklerometers. K. Balyi. *Földtani Kozlony* 68, 59–67(1938); *Neues Jahrb. Mineral., Geol.*, Ref. I. 1939, 25.—An improved form of Kuznetsov and Lavrent'eva's sklerometer (*C. A.* 26, 12) is described, the chief difference being that the 90° wedge with which the pendulum ends has a portion 1 mm. wide filed so as to make a pair of blunter wedges. Details as to use and method of calcg. H are given. C. A. Silberrad

A new and novel Freon refrigerating machine. J. B. Ritter. *Natl. Engr.* 43, 589–90(1939). A. N. H.

Some practical considerations on temperature control. Luis De Florez. *News Ed. (Am. Chem. Soc.)* 18, 102-3 (1940).—In cracking oil, control of temp. and flow not only dets. quality of product but the ability to operate continuously. Disturbances must be analyzed and corrected; it is found that there is a similarity in these factors to those used in the math. equation for a damped pendulum. Controls must be arranged to care for the time factor, fuel-oil ratio, temp. gradients along the coil, etc., automatically resetting other controls for temp., flow, and pressure. Improvements in multiple-junction thermocouples with amplifying devices are suggested, and coordination between process, operating, and instrument forces is stressed. W. C. Ebaugh

Vacuum thermocouples of the radiation-type pyrometry. S. S. Stack. *Gen. Elec. Rev.* 42, 365 6(1939).—The radiation pyrometer responds to intensities of all wave lengths. The energy radiation from the hot object is focussed on a blackened hot junction of a vacuum-enclosed thermocouple element. The thermocouple generates an e. m. f. which is approx. proportional to the temp. rise of the hot junction, or $E = 65K(T^4 - T_0^4)$ where K is a const., T the abs. temp. of the hot object and T_0 that of the thermocouple. The element is a thin metal strip (0.001 mm. thick) mounted between 2 heavy anchor supports which serve as the lead wires and as the cold junctions for the couple. The e. m. f. is 65 microvolts/1°. The hot junction is at the center of the strip where the 2 metals are joined in the form of a line across the strip (compn. not given). C. G. F.

Relation of uniform pyrometer records to uniform products. J. A. Doyle. *News Ed. (Am. Chem. Soc.)* 18, 135–7 (1940); *Heat Treating Forging* 25, 604–8(1939).—Emphasis on temp. control often leads to disregard of other important factors affecting uniformity of product, and the real test of uniformity is in the product. Direct relations exist between the surface exposed, time and rate of heating and cooling, positions of articles undergoing heating, and atm. conditions present. Much of the inequality frequently attributed to material is due to unsound shop practice in heating and cooling, and reflects the custom of disregarding the influence of phys. factors other than heat that affect uniformity. "Process specification" has been suggested as a means to the desired end. W. C. E.

Importance of the atmosphere in industrial furnaces. R. Martin. *Gas World* 111, No. 2889 Ind. Gas Suppl., 136–8(1939); 112, No. 2894 Ind. Gas Suppl., 6–8(1940). —See *C. A.* 34, 662⁷. P. J. Wilson, Jr.

Electric relay circuit for a thermostat. Kenzo Harai. *J. Chem. Soc. Japan* 60, 1258–60(1939).—A bulb is utilized for the temp. regulation of a thermostat, and the working conditions are studied. T. Katsurai

Metal containers for shipping and storing white lead and similar materials (U. S. pat. 2,182,813) 26.

Kieser, A. J.: Handbuch der chemisch-technischen Apparate, maschinellen Hilfsmittel und Werkstoffe. Lfg. 15. Berlin: J. Springer. 92 pp. Cf. *C. A.* 34, 1519¹.

Twenhofel, W. H.: Principles of Sedimentation. New York: McGraw-Hill Book Co. 610 pp. $6.00.

Shell and tube converter for chemical reactions or contact treatments. Thomas B. Prickett (to Houdry Process Corp.). U. S. 2,181,153, Nov. 28. Various structural details.

Hermetic closures for bottles and like containers for corrosive liquids. Mallinckrodt Chemical Works. Brit. 507,702, June 20, 1939.

Specific gravity indicator. Howard H. Decker (to Schutte & Koerting Co.). U. S. 2,182,172, Dec. 5. Various details of a device with a float and indicator suitable for indicating the sp. gr. of fluids in tanks to which the device may be attached.

Multiple gravity meter. Frank G. Boucher (to Standard Oil Development Co.). U. S. 2,183,115, Dec. 12. Various structural, mech. and operative details.

Thick walled pressure vessels such as drums and headers of different steels. Howard J. Kerr (to Babcock & Wilcox Co.). U. S. 2,183,043, Dec. 12. Various structural details of app. which may include different metals such as chrome steel and C Mo steel welded to each other.

Apparatus with a deflector for proportioning reflux in distillations, etc. Thomas M. Gunn (to Socony-Vacuum Oil Co.). U. S. 2,182,378, Dec. 5. Various structural and operative details.

Hydrogen-ion concentration meter. Donald H. Cameron (to B. D. Eisendrath Tanning Co.). U. S. 2,181,866, Dec. 5. An app. is used comprising, in combination, a glass electrode, a thermionic tube in close proximity thereto, a short conductor connecting the electrode to the grid of the tube, a circuit including in series, a measuring potentiometer and a standardizing potentiometer, connecting the electrode to the cathode of the tube, the potentiometers being located in remote relation to the thermionic tube, and a relay located adjacent to the potentiometers for eliminating the glass electrode and measuring potentiometer from the circuit. U. S. 2,181,867 relates to an app. suitable for making chart records of pH concns.

Apparatus for cleaning filter beds such as those of sand. Francis L. Pruyn. U. S. 2,182,094–5, Dec. 5. Various structural, mech. and operative details.

Supports for filter pads. Oscar E. Quave and Ben B. Breslow (to Utility Fan Corp.). U. S. 2,182,501, Dec. 5. Various structural details.

Cleansing absorbent filtering material such as active carbon containing solvent material such as trichlorethylene. Edgar R. Sutcliffe and William E. Edwards (Edwards to Sutcliffe, Speakman & Co. Ltd.). U. S. 2,181,672, Nov. 28. Various details of app. and of use of steam as a filter-cleaning medium are described.

Apparatus for separating suspended solid matter from gases. Thomas B. Allardice. U. S. 2,182,862, Dec. 12. Various structural and operative details.

Apparatus for trapping out dust from air. Henry W. Pfeffer and Harry O. Danz (to American Blower Corp.). U. S. 2,182,854, Dec. 12. Various structural details. 1

Spray tower for removing fine particles from gases by sprays of liquid. Reginald G. Bowman (to Traufhber Engineering Co.). U. S. 2,182,533, Dec. 5. Various structural and operative details.

Valve suitable for controlling the flow of gases under pressure. Marvin H. Grove. U. S. 2,181,428, Nov. 28. Various structural and operative details. 2

Apparatus for bringing gases into contact with liquids. Robert V. Kleinschmidt (to Arthur D. Little, Inc.). Can. 386,611, Jan. 30, 1940. Structural details.

Apparatus suitable for washing gases and similar operations. Robert G. Guthrie and Oscar J. Wilbor (to Peoples Gas By-Products Corp.). U. S. 2,183,071, Dec. 12. Various structural and operative details.

Rotor unit for spraying liquids such as those for washing gases. Herbert A. Faber. U. S. 2,182,471, Dec. 5. Various structural details. 3

Atomizing liquids, as in humidifying air. Albert J. Loepsinger (to General Fire Extinguisher Co.). U. S. 2,182,897, Dec. 12. Various details of app. and operation.

Syphonic apparatus for delivering measured quantities of liquids from bottles, etc. Harold G. Conrade and Lawrence T. Payne. Brit. 507,771, June 21, 1939. 4

Apparatus with conical devices for separating suspended solids from liquids such as waste lye from sulfate cellulose production. Isak E. Johansson. U. S. 2,181,456, Nov. 28. Various structural details of an app. in which a helical motion and centrifugal action facilitates clarification of liquids.

Screw and hopper apparatus suitable for feeding powdered or granular materials. Guy L. Rigor (to St. Regis Paper Co.). U. S. 2,181,205, Nov. 28. Various mech., structural and operative details. 5

Steel balls for ball mills. Charles W. Hagenbuch and Frederick A. McCoy (to Sheffield Steel Corp.). U. S. 2,182,805, Dec. 12. Balls suitable for use in grinding are formed of heat-treated C-Mn-Mo steel alloy hardened throughout from the outer surface to the center and with a deep wearing zone in the surface portion and a central solid core of coarser grained structure, the alloy used contg. C 0.6–1.1, Mn 0.3-1.1, Mo 0.1–0.8, impurities not more than 0.3, and Fe not less than 96.7%. 6

Tube or ball mill suitable for grinding wet materials. Joseph E. Kennedy (to Kennedy-Van Saun Mfg. & Eng. Corp.). U. S. 2,181,943, Dec. 5. Various structural, mech. and operative details.

Impact crusher. William H. Schacht. Can. 386,679, Feb. 6, 1940. Structural details.

Multiple-stage impact crushing. William H. Schacht. Can. 386,680, Feb. 6, 1940. Operative details are described. 7

Apparatus for gasifying solid carbon dioxide. Roy E. McIlrath. U. S. 2,181,195, Nov. 28. Various structural details.

Condenser. Joseph J. Thompson (to Kellogg Co.). U. S. 2,182,183, Dec. 5. Various structural details of an app. suitable for condensing vapors of a solvent used for extg. caffeine from coffee or for similar purposes. 8

Apparatus for gas treatments of molten materials, as in removing carbon from iron or its alloys. Adolf Vogt (to Alex. Wacker Ges. für elektrochemische Industrie G. m. b. H.). U. S. 2,182,064, Dec. 5. An app. for treating hot molten materials with a gas such as O at low pressure comprises a container having an opening and a closed casing surrounding the container, the container having walls of nonporous material which are lined internally with a high-temp. resisting porous lining, the walls being provided with a plurality of openings whereby the air or gas contained in the lining escapes through the openings into the outer space enclosed by the casing. 9

Apparatus for immersing articles in plating baths and performing other like operations involving traversing and periodic raising and lowering. W. Canning & Co. Ltd. and Ernest R. Canning. Brit. 508,246, June 28, 1939.

Long-tube vertical evaporator. Floyd H. Walker (to (Whiting Corp.). U. S. 2,181,750, Nov. 28. Various structural details.

Centrifugal drier. Edward L. Miller (to American Machine and Metals, Inc.). U. S. 2,182,346, Dec. 5. Various structural details.

Drying and heating apparatus. Geo. R. Lewers (to Underpinning & Foundation Co.). U. S. 2,181,190, Nov. 28. Structural details.

Retorts. Wilhelm Groth. Brit. 507,986, June 23, 1939. In an annular shaftlike distn. retort with central introduction of flushing gas and a heat-exchange chamber arranged underneath the distn. chamber, from the gas-collecting space of which heat-exchange chamber the preheated flushing gas is withdrawn and passed through a heater before being admitted to the distn. chamber, 2 concentric pipes enter from below centrally into the heat-exchange chamber, the space between these pipes being used for the delivery of cold flushing gas and terminating in the lower part of the heat-exchange chamber while the inner pipe serves for the delivery of the heated flushing gas and extends upward into the lower part of the distn. chamber.

Apparatus for the central introduction of flushing gas into an annular shaft-like retort. Georg Merkel. Brit. 507,985, June 23, 1939. The inner wall bounding the distn. space is formed by 2 pipes arranged 1 above the other and sepd. by an interval, the upper pipe being closed by a flat or arched base shielding the open mouth of the lower pipe which serves for the introduction of the flushing gas.

Protecting retorts such as those of various kiln stokers against high temperatures. Ross C. Johnson. U. S. 2,181,371, Nov. 28. Stoker app. involves the combination with a fire-box having an opening in the base thereof to atm., and a retort therein spaced from the walls of the box and having tuyère openings in the upper portion thereof, of a partition member extending across the fire-box between the tuyère openings of the retort and the air opening of the fire-box and dividing the fire-box into a combustion chamber and a cooling chamber, the partition comprising a stationary section having a dumping door therein for establishing communication between the combustion chamber and the cooling chamber, and means extending outwardly of the fire-box for operating the door to open and close the same.

Roller-rail assembly for use in heat-treating furnaces. Henry H. Harris. U. S. 2,182,202, Dec. 5. Structural and mech. details.

Heat-exchange apparatus suitable for heating air with steam. Marcus E. Fiene (to General Elec. Co.). U. S. 2,181,726, Nov. 28. Various structural and operative details.

Tube and shell heat-exchange apparatus suitable for use in high-temperature chemical operations. James M. Jenkins (to Andale Co.). U. S. 2,181,486, Nov. 28. Various structural details.

Tube and shell heat-transfer apparatus suitable for cooling gases or vapors. Daniel R. McNeal (to Andale Co.). U. S. 2,181,704, Nov. 28. Various structural details.

Tube and header heat-exchange apparatus suitable for use with water, etc. Wm. C. Keeran (to Vapor Car Heating Co.). U. S. 2,181,602, Nov. 28. Various structural details.

Reversible heat-transfer apparatus suitable for various heating or cooling systems. Harry R. Crago (to General Elec. Co.). U. S. 2,182,691, Dec. 5. Various details of thermostatic control, etc.

Heat-exchange apparatus suitable for condensing steam. Albert J. Townsend. U. S. 2,181,927, Dec. 5. Various structural details.

Carburizing box suitable for use in heat-treatments. Henry H. Harris. U. S. 2,182,201, Dec. 5. Structural details.

Heat-transfer process suitable for refrigerating systems. Wm. H. Sellew. U. S. 2,182,453, Dec. 5. App. is de-

scribed, and a cyclic process utilizing at least 2 solns. having a common solvent, such as aq. NaOH solns. of different strength, in which solvent is vaporized from the second of the solns., absorbed into the first of the solns. at a temp. at least as high as the temp. of vaporization from the second soln., and the entire heat effect accompanying the vapor absorption is absorbed in a medium within the cycle, such absorbed heat being subsequently rejected from the cycle at a higher temp.

Heat-transfer processes for refrigerating, etc. Wm. H. Sellew (to P. R. Mallory & Co.). U. S. 2,182,098, Dec. 5. Various features of app., materials used, and operative details are described suitable for a continuous soln. cycle heat-transfer process which includes the vaporization of a volatile component from a soln., the subsequent condensation of such vapor, the absorption of the heat effect accompanying such condensation by a second similar soln., the vaporization thereby of a volatile component from the second soln. at a lower temp. than that at which the volatile component was originally vaporized from the first soln., successive repetitions of this step with the absorption of the heat effect accompanying the last condensation by a dissimilar soln. and the vaporization thereby of a volatile component from the dissimilar soln. at a lower temp. than that at which the first volatile component was vaporized and the subsequent utilization of the vapor so formed from the dissimilar soln., the dissimilar soln. having a different elevation in b. p. temp. than the first soln. when the two solns. are in thermal contact, the two solns. being of different chem. compn., such as solns. of NaOH and of NH_3.

Absorption refrigerating apparatus. Curtis C. Coons (to Hoover Co.). U. S. 2,181,561, Nov. 28. Various structural and operative details.

Absorption refrigerating apparatus suitable for use with ammonia. Nils Widell (to Servel, Inc.). U. S. 2,181,528, Nov. 28. Various structural and operative details.

Continuous absorption refrigerating apparatus suitable for use with ammonia. Nils Widell (to Servel, Inc.). U. S. 2,181,221, Nov. 28. Various structural and operative details.

Anselme Payen—discoverer of cellulose. J. David Reid and E. C. Dryden. *Textile Colorist* 62, 43-5(1940).—A historical review of the work of Payen, who showed in 1838 that wood was composed of at least two parts, one of which he called "cellulose" and the other "incrustant material." Ruby K. Worner

Anselme Payen, distinguished French chemist and pioneer investigator of the chemistry of lignin. Max Phillips. *J. Wash. Acad. Sci.* 30, 65-71(1940). E. H.

How Hans Christian Oersted paved the way for the practical use of aluminum. M. H. Haas. *Aluminium* 21, 810-23(1939).—In continuation of *C. A.* 34, 293[8] this part describes the work and reproduces the original publications and German translations relating to the practical production of Al. Recently, Oersted's process according to $3K + AlCl_3 = 3KCl + Al$ was revised, but found to be not quite correctly represented by this formula which in fact should read $3K + 4AlCl_3 = 3KAlCl_4 + Al$, so that K Al chloride is obtained as a by-product and not KCl. These expts. are described at length. M. H.

Quantitative investigation of prehistoric metal objects. Helmut Otto. *Nachrbl. deut. Vorzeit* 14, 71-4(1938); *Neues Jahrb. Mineral., Geol.*, Ref. II, 1939, 213.—The results, as regards compn. and probable origin of the ores of the constituent metals of some 850 prehistoric, mostly late Bronze Age metallic articles is discussed. C. A. S.

Employment of mid-German ores in the early Bronze Age. Helmut Otto. *Forschungen u. Fortschr.* 14, 298-9 (1938); *Neues Jahrb. Mineral., Geol.*, Ref. II, 1939, 212-13.—As a result of spectroanalytical examn. of some 460 metal articles of early Bronze Age, the probable ores from which their constituent metals were derived were detd. C. A. Silberrad

Molecular or short-path distillation. H. I. Waterman and C. van Vlodrop. *Rev. chim. ind.* (Paris) 48, 314-22 (1939).—A review with 25 references. E. H.

Cleaning of a Babylonian tablet. Elisabeth Packard. *Tech. Studies Field Fine Arts* 8, 90-7(1939).—A badly cracked baked clay tablet with its surface in a flaking condition and its inscriptions obscured by incrustation could not be cleaned by phys. methods and immersion in HCl. It was, therefore, placed under a binocular microscope (16 ×) and a small cotton swab dipped in 5% HCl soln. applied to the incrustation which was of 2 kinds. The $CaCO_3$ dissolved and was easily removed with the swab and the siliceous material was softened so that it could be removed by phys. means. Lastly, a 10-20% soln. of polyvinyl acetate was allowed to flow into the cracks and flaking sections and allowed to dry out for several days between applications. Surplus polyvinyl acetate was removed from the surface with acetone. A. H. Krappe

Chemical studies in lake metabolism. Ken Sugawara. *Bull. Chem. Soc. Japan* 14, Suppl. 375-451(1939).—The term "lake metabolism" is introduced to cover the relations among the factors governing the cycles of changes in the life and compn. of lakes and lake waters. A detailed study of the variation in the compn. of lake muds, and their temp., pH, bacterial counts, etc., at different depths and seasons was made on 5 Japanese lakes. Deposition, N content, etc., reach a max. about November. The total N decreases with depth. Numerous tables are given, summarizing the findings. Thirty-one references. Marcelle Schubert

The salt and phosphorus content, the temperature and the flow of water, as well as the wind velocities, in the Irbesch narrows, measured from the lightship "Laima." E. Zariņš and J. Ozoliņš. *Acta Univ. Latviensis, Kim. Fakultat.* Ser. 4, No. 13, (in Lettish, 473-99; in German, 500-2)(1939).—Daily samples of water collected at 0 and

at 15-m. depths, at 7:00 a. m., in the narrows connecting the Bay of Riga with the Baltic sea from June, 1937, until June, 1938, show that the salt content depended upon the direction of water flow which in turn depended upon the direction and velocity of the wind. The water temp. depended upon the air temp.; at 0 meters it reached a min. of +0.3° in Jan. and a max. of 19.5° in Aug.; at 15 m. it reached a min. of +0.6° in Jan. and a max of 16.5° in Sept. At 0 meters the salt content attained a max. of 7.05% in Nov. and a min. of 6.15% in Aug.; at 15 m. the salt content attained a max. of 7.06% in Nov. and a min. of 6.49% in Sept. If the temp. of the water rose, the salt content fell, and reversely. The content of P_2O_5 could not be related to the salt content, the temp. or flow of water; due to the activity of the phytoplankton the P_2O_5 remains at a low level. At 0 meters it reached a max. of 13 mg. P_2O_5 per cu. m. in March and a min. of 4 mg. in Jan.; at 15 m. it reached a max. of 15 mg. in March and a min. of 4 mg. in Sept. The P content was higher at the lower levels because of the absence of the plankton. In contrast to the waters from the Bay of Riga, the waters from the Baltic sea contained more P. Water from the Bay of Riga contains only 5% salt. Because the water at the 0 and 15-meter strata does not move in the same direction, the changes in the temp. and salt content in these 2 strata do not correspond. Frank Maresh

Limiting densities and molecular weights of oxygen, carbon dioxide and hydrogen sulfide. Atomic weights of carbon and sulfur. E. Moles, T. Toral and E. Escribano. *Trans. Faraday Soc.* **35**, 1439–52(1939); cf. *C. A.* **33**, 1189⁸.—For the three gases used the limiting pressure vs. the pressure is a linear plot within the limits of the exptl. error, namely, 1 in 100,000 on an individual ratio. The at. wt. of C is 12.007 ± 0.0002 and that of S is 32.063. Victor R. Deitz

Determination of the molecular radii of organic liquids from density and the velocity of sound. Werner Schaafs. *Z. Physik* **114**, 110–15(1939).—Under simplifying assumptions an expression for mol. radius as a function of d. and the velocity of sound is derived. The values obtained for many substances are close to those computed from the mol. refraction. E. J. Rosenbaum

Connections between the velocity of sound and the constitution of organic compounds. Werner Schaafs. *Z. Physik* **114**, 251–6(1939); cf. preceding abstr.—The values of the van der Waals' *b* were computed for a no. of org. compds. from velocity-of-sound data by a method previously published. From 17 of these values the contributions to *b* arising from the various kinds of bonds were obtained. To test the assumption that these contributions are additive, the *b* values for 32 other compds. found by use of this assumption were compared with those computed from the velocity of sound. The agreement is good. E. J. Rosenbaum

Non-adiabatic processes in an oscillating magnetic field. P. Caldirola. *Nuovo cimento* **16**, 242–52(1939).—A math. study of the action of an oscillating magnetic field on a system having an angular and a magnetic moment moving in the direction of a fixed field. J. B. A.

The magnetic susceptibility of methemoglobin. Paulette Berthier. *Compt. rend.* **209**, 774–6(1939).—Working at 11°, with methemoglobin (I) prepd. at low temp. and kept at 0° until used, B. found that (1) in the presence of HCl I remains paramagnetic and becomes increasingly paramagnetic on standing; (2) with NaOH in low concn. I is paramagnetic but becomes diamagnetic as pH increases. The values of the magnetic susceptibility $k_0 \times 10^6$ at different pH's are: 1.1, +0.46; 3.2, +0.04; 7.2, +0.15; 8.2, −0.18; 14.0, −6.21. Flocculation of I occurs between pH 1.1 and 3.2. In pure H_2O at pH 7.2, k_0 remains const. with time. Marcelle Schubert

The heat effect at the "paramagnetic Curie temperature" of vanadium dioxide. W. Klemm and L. Grimm. *Naturwissenschaften* **27**, 787(1939).—Hoschek and K. showed the presence of a "paramagnetic Curie temp." for $VO_{1.9}$ to $VO_{2.1}$ between 60 and 70° (*C. A.* **33**, 8133⁷). The expected heat effect at this point was likewise found: −1.1 kg.-cal per mol. for $VO_{1.9}$, −0.8 for VO_2, −1.1 for $VO_{2.1}$. The difference between the heat effect at stoichiometric compn. and above or below it is interesting; it shows up also in the sp. heat values for these compns. B. J. C. van der Hoeven

Magnetothermal properties of some anomalous paramagnetic salts at low temperatures. G. A. Milyutin and S. S. Shalyt. *Compt. rend. acad. sci. U. R. S. S.* **24**, 680–2(1939)(in English).—The magnetothermal properties of anhyd. $FeCl_2$ (I), $CoCl_2$ (II) and $CrCl_3$ (III) were investigated at low temp., by means of a vacuum calorimeter and a magnetic field of 1000–11,000 gausses. The magnetocaloric effect was found neg. for I and II and pos. for III and linear in all cases. For I the effect was found pos. at 14.2°K. and H = 5500 gausses, imperceptible at H = 9500 gausses and neg. at H = 11,100 gausses. A superposition of two effects is believed to take place where the pos. effect is assocd. with the orientation of magnetic carriers in the external magnetic field and the neg. effect is accounted for by the increase of the potential energy of the orbital moments in the elec. field of the crystal due to their being forced out of their quenched positions. The magnetocaloric effect in III was found pos. above and below the sp. heat jump (16.8°K.). Application of a magnetic field caused a shift in the sp. heat jump toward a lower temp.—of 0.4°K. for I, 0.7°K. for II and could not be detd. for III. Frank Gonet

The theory of paramagnetic relaxation. H. Dänzer. *Physik. Z.* **40**, 557–9(1939).—Math. D. demonstrates the connection between the thermodynamic theory of Casimir and du Pré (*C. A.* **32**, 6918⁴) and that of Kronig (*C. A.* **33**, 3222⁶). J. B. Austin

Influence of molecular form and free rotation of dipole groups on dielectric relaxation. A. Budó. *Physik. Z.* **40**, 603–11(1939).—Math. The mean mol. moment in a high-frequency field is calcd. on the basis that the mols. have n free rotating groups whose axis of rotation remains fixed with reference to any mol. coördinate system. For frequencies not too high, the mean dipole moment is given in terms of n + 3 relaxation times. J. B. A.

Dielectric relaxation phenomena in relation to molecular and intermolecular structure of dipole liquids. Erich Fischer. *Physik. Z.* **40**, 645–63(1939).—Dielec. loss is detd. in C_6H_6 soln. as a function of concn. in the range below 1.5 mol. % for: acetone, EtCOEt, dipropyl ketone, dibutyl ketone, MeOH, EtOH, C_3H_7OH, $C_4H_{13}OH$, C_6H_{17}-OH, cetyl alc., $C_8H_{17}Cl$, $C_8H_{17}Cl$, $C_{16}H_{31}Cl$, lauryl chloride, cetyl chloride, C_3H_7Br, $C_8H_{13}Br$, cetyl bromide, $C_6H_5NO_2$, C_6H_5Cl, *o*-$C_6H_4Cl_2$, 1-chloronaphthalene, 1-chloroanthraquinone, 2-chloroanthraquinone, 2,3-dichloroanthraquinone, 1,8-dichloroanthraquinone. For mols. of fixed moment the effect of mol. size and form is given by Perrin's theory and by the tables of Budó, Fischer and Miyamoto (*C. A.* **33**, 7633⁵) which are based on mol. friction of elliptical particles. For mols. other than spherical, which have an axis of free rotation, the variation of relaxation time with the direction of the moment relative to the axis of rotation is given qualitatively by the theory. The effect of rotational hindrance potentials is discussed. For aliphatic chain mols. the magnitude of the relaxation time and the increase with length of chain are related to the different moment directions and to the freely rotating groups. The abs. magnitude of the relaxation time in dil. solns. is explained on the basis of mol. viscosity which is a const. fraction of macroscopic viscosity. Taking viscosity effects into account, the relaxation time of pure acetone, $C_6H_5NO_2$ and C_6H_5Cl agrees with Debye's quasi-cryst. structure. The alcs. do not indicate this structure but are discussed in terms of a special structure. J. B. Austin

Dielectric losses due to relaxation in glasses at high frequencies. Yu. Skanavi. *J. Tech. Phys.* (U. S. S. R.) **9**, 612–23(1939).—Theoretical. Dielec. losses in amorphous bodies are due at low frequencies to relaxation and cond., and at high frequencies also to structural losses. The fraction due to relaxation is calcd. on the assumption that it is caused by ions of admixts. which are present in the "pores" of the body. The final equation contains the

radius of the spherical pores and the min. energy of the ions able to cross them. J. J. Bikerman

Dielectric losses due to polar molecules in solid paraffin wax. D. R. Pelmore. *Proc. Roy. Soc.* (London) **A172**, 502–16(1939).—The dielec. losses of solns. of spermaceti in 9 paraffins of various setting points and in hexadecane, octadecane and docosane were detd. over various temp. ranges. The behavior of ethyl stearate was compared with that of spermaceti in a paraffin of chain length about 26 C atoms and in hexadecane. The results show that the chain length of the ester is without effect on the relaxation time provided that this chain is longer than that of the mols. of the paraffin matrix. The absorption in hexadecane was found to be much greater than in the harder wax. Expts. with dioctyl sebacate and dioctyl azelate in a paraffin of setting point 57–60° showed that the dielec. loss was pos. or negligible according to the relative sense of the two polar groups. When these were arranged so that the dipole components transverse to the chain had opposite sense, no dielec. loss was observed; when the dipole components had the same sense, the dielec. loss had a max. value at any given temp. for a particular frequency. The relaxation time corresponded closely with that anticipated from chain length. The expts. seem to confirm the conclusion that the dielec. losses are due to rotation of C chains about their long axes. H. C. Thomas

The dielectric constants of some oxides, hydroxides and hydrated oxides. Oskar Glemser. *Z. Elektrochem.* **45**, 865–70(1939); cf. *C. A.* **32**, 3245[1], 6516[9].—The dielec. consts. of hydroxides and oxides of Al, Be, Mg, Zn and Fe and of the hydrated oxides of Fe were obtained by the immersion method of measurement. The importance of the choice of condenser is stressed. Synthetic (finely divided) materials gave a much higher dielec. const. than the corresponding minerals. The mobility of the atom group is greater in the former than in the latter. The increased displacement polarization means a higher dielec. const. The dielec. consts. of amorphous ferric hydrated oxide, α-FeOOH (goethite), and γ-FeOOH (goethite), including their dehydration products, were measured. At different temps. abnormally high dielec. consts. occur, because of Fe_3O_4 formation. M. McMahon

Thermodynamic properties of substances. III. Vapor volumes as functions of reduced temperature alone. Harold A. Fales and Clara S. Shapiro. *J. Am. Chem. Soc.* **62**, 393–406(1940); cf. *C. A.* **32**, 1267[6], 4400[8,9].—The reduced vapor vol. of chemically different substances is found to be an exponential function of reduced temp. alone. The form of this function is identical with those for vapor pressure and for vol. ratio; it is $\ln V_g/V_{cr} = k''(1-\tau^2)^{m''}/\tau^{n''} = x$, where $V_{gas} = V_{cr}.e^x$. The accuracy of this equation is well within exptl. limits and is in good agreement with vapor-vol. equations of other investigators. Data are given for 30 gases. An extensive bibliography is given on exptl. data for vapor vols. and crit. properties as well as exptl. test equations used by different observers. The parameters of this equation and the results of their application are discussed generally. A. B. Garrett

Thermodynamic surfaces of water. Arthur Lewis Clark and L. Katz. *Trans. Roy. Soc. Can.* III, **33**, 59–72(1939).—A *P-V-T* surface was constructed to represent H_2O in its vapor, liquid and various solid modifications. Another surface using vol., entropy and internal energy as coördinates (Gibbs surface) was built to represent water, water vapor and ice in the region around the triple and crit. points. The Gibbs surface is compared with others built by Kamerlingh Onnes, Boynton, Zemansky and Maxwell. The main point of difference is in the slope of the satd. vapor curve in equil. with the solid. In the model described a neg. sp. heat of satn. is used. J. W. Shipley

Phase equilibria in hydrocarbon systems. Joule-Thomson coefficients for gaseous mixtures of methane and *n*-butane. R. A. Budenholzer, B. H. Sage and W. N. Lacey. *Ind. Eng. Chem.* **32**, 384–7(1940); cf. *C. A.* **33**, 9106[9].—Joule-Thomson coeffs. for 5 mixts. of methane and *n*-butane were detd. exptly. for 5 temps. between 70° and 310°F. at pressures between 50 and 1500 lb. per sq. in. abs. From these data, together with the isobaric heat capacity at infinite attenuation, the heat capacities of several mixts. were calcd. as functions of pressure and temp. The results are presented in graphic and tabular form. F. L. Browne

Method for separating para-hydrogen from oxygen and carbon monoxide. E. Bergmann, L. Farkas and L. Sandler. *J. Am. Chem. Soc.* **62**, 445(1940).—O was absorbed by a satd. soln. of Ph_3CNa in Bu_2O contg. solid Ph_3CNa; 20 cc. of this soln. will absorb 130 cu. m. of O; under these conditions there is no appreciable conversion of para-hydrogen. CO was absorbed by Cu_2O-NH_3 soln. C. J. West

Boiling points of the system of formic acid and water. Sotozi Takagi. *Bull. Chem. Soc. Japan* **14**, 508–9(1939) (in English).—The b. ps. of the binary system HCO_2H–H_2O were detd. for concns. of HCO_2H between 95.6 and 16.9% and pressures of 25, 49, 100, 252 and 774 mm. Hg. The data for the azeotropic mixts. were obtained by carrying out the expts. to the coincidence of const. b. ps. starting from samples of higher and lower concns. than that of the azeotropic mixts. The results obtained are thus of considerable accuracy, i. e., the error is within ±1° in temp. and within ±0.1% in compn. Dora Stern

Some thermodynamic parameters of antimony trichloride. D. I. Zhuravlev. *J. Tech. Phys.* (U. S. S. R.) 9, 1331–2(1939).—Vapor pressure, d. of liquid and vapor, and heat of vaporization of $SbCl_3$ are tabulated for the temp. interval between m. p. and crit. temp. J. J. B.

New applications of the parachor. Petru Bogdan. *Bull. sect. sci. acad. roumaine* **22**, 104–8(1939); cf. *C. A.* **33**, 6674[1].—A so-called new parachor $P_n = T^{1/4} V^{1/4}$ where T is the abs. b. p. and V is the mol. vol. at that temp. is developed. Illustrations of the calcn. are given and the values are listed for some 46 compds. The value of the new expression lies in the fact that only the b. p. needs to be detd., as values of mol. vols. can be obtained by the use of suitable consts. A. A. Vernon

New methods of measuring the viscosity of viscous liquids with rising temperatures. K. Göhde. *Chem. Fabrik* 1940, 9–11.—A detailed description, with 1 cut and 7 graphs, of the "viscograph," with which low or high viscosities can be accurately and quickly detd. with continuously varying temp. J. H. Moore

The absorption of ultrasonic waves by acetone-water mixtures. P. A. Bazhulin and Yu. M. Merson. *Compt. rend. acad. sci. U. R. S. S.* **24**, 690–1(1939) (in French).—The coeff. of absorption (α) of the system acetone-water was measured at frequencies from 19,000 to 3800 kilohertzes; it reached a max. at 60 to 70% acetone. The coeff. was found to vary inversely as the temp. in the range 20–38°. Frank Gonet

Experiments on the molecular structure of liquids by means of models. W. Kast and H. A. Stuart. *Physik. Z.* **40**, 714–18(1939).—The models are small circular or roughly elliptical disks of brass or Al. Dipoles are introduced by attaching magnets. A large no. of disks are shaken on a glass plate and the groupings observed. Mols. of Hg, HCl, CCl_4, CS_2 and HCN are simulated. Expts. are made with different densities of packing. J. B. A.

Melting as a disorder phenomenon. K. Wirtz. *Metallwirtschaft* **18**, 843–6(1939); cf. *C. A.* **33**, 4484[9].—A résumé of the latest theories on melting. 10 references. H. S. v. K.

Factors influencing the thermal conductivity of non-metallic materials. J. B. Austin. *Am. Soc. Testing Materials, Symposium on Thermal Insulating Materials* 1939, 3–67.—A survey is made of all factors recognized as, or suspected of, influencing thermal cond. In general, those compds. that crystallize in a lattice of high symmetry, such as MgO, are better conductors than more complex compds. such as $2MgO.SiO_2$. Among the simpler compds., the best conductors are those whose mols. have most nearly the same wt. and electronic structure. Thermal cond. increases with increasing purity. Phys. texture has a greater effect on cond. than any other single factor. Two ideal structures are considered. The first,

that of pores embedded in a solid matrix, resembles a sponge. The cond. of a material having this structure decreases approx. linearly with increasing porosity and the cond. of the aggregate is but little affected by the relative conductivities of the 2 phases. The 2nd structure, that of solid grains surrounded by air, resembles a powder. The cond. of a material having this structure decreases approx. logarithmically with increasing porosity and is greatly affected by the cond. of the air-sepg. grains. For many amorphous substances (and many com. materials such as refractory brick can be considered amorphous) the thermal cond. increases linearly with temp. For single crystals the cond. decreases markedly with increasing temp. There is no well-established variation of thermal cond. with heat flow. Various methods of reporting measurements, such as true cond. and mean cond., are discussed and compared. J. B. Austin

Electrical conduction of commercial boron crystals. J. H. Bruce and A. Hickling. *Trans. Faraday Soc.* **35**, 1436-9(1939).—Observations with d. c. and a. c. on the elec. cond. in B crystals are described. Neg. resistance is developed in a short time and for a given crystal the results are consistent. Relatively enormous currents (sufficient to produce red heat) which the small crystal carried did not prevent the path of resistance from being approx. reversible. The a. c. data were recorded photographically. Victor R. Deitz

Electrical conductivity of metals. John Bardeen. *J. Applied Phys.* **11**, 88–111(1940).—Review. S. L. G.

Temperature coefficients of cuprous oxide rectifiers. M. I. Vitenberg. *J. Tech. Phys.* (U. S. S. R.) **9**, 1315–24(1939).—The elec. resistance of 18 Cu_2O rectifiers was measured between −19 and 50° for both directions of the current. It was possible to define a magnitude independent of the c. d. and to calc. the temp. dependence of the rectifying effect. J. J. Bikerman

Piezoelectric polarity and symmetry of some crystals. I. A. Bellanca. *Periodico mineral.* (Rome) **9**, 323–31(1938); *Mineralog. Abstracts* **7**, 246–7(1939).—The piezoelec. behavior of gypsum proves it to be holo- and not hemi-symmetric. C. A. Silberrad

Application of a new photoelectric method to the determination of the optical constants of some pure metals. J. Bor, A. Hobson and C. Wood. *Proc. Phys. Soc.* (London) **51**, 932–41(1939).—An optical system is described, for the detn. of optical consts. of metals, which includes a pair of photoelec. cells; one replaces the eye and the other compensates for unsteadiness of light source. A Lindemann electrometer is utilized for detg. extinction positions. The n and extinction coeff. obtained for Cu, Ni, Cr, Pd and Zn are tabulated for the range of 4000–11,000 A. The ns obtained for Cu and Ni differ slightly in magnitude from those previously reported, but the n-wave length curves are parallel. H. A. Frediani

Optical constants of copper-nickel alloys. J. Bor, A. Hobson and C. Wood. *Proc. Phys. Soc.* (London) **51**, 942–51(1939).—The n, extinction coeff. and absorption coeff. for pure Cu, pure Ni and 13 intermediate alloys were detd. in the range 4000–10,000 A. The absorption band is shifted about 500 A. (to shorter wave lengths) as the Ni content is increased from 0 to 17%. No absorption band was found for Ni concns. above 25%. The min. in k (extinction coeff.) changes from 5600 A. in pure Cu to 6000 A. for 17% Ni. No min. appears above 25% Ni. The effect of varying concns. in these alloys on the optical properties is shown graphically. H. A. Frediani

The optical absorption of superconducting films of tin. R. Hilsch. *Physik. Z.* **40**, 592–4(1939).—The change to the superconducting state is not accompanied by a measureable change in transparency within the range 3800 to 9000 A. Colloidal Pb and Tl in KCl crystals produce no change in absorption at liquid-He temps. J. B. Austin

Optics of extremely thin metallic films. D. Hacman. *Z. Physik* **114**, 170–7(1939); cf. *C. A.* **33**, 6151[5].—Theoretical. E. J. Rosenbaum

Temperature dependence of the diffusion constants of atomic hydrogen and of protons in iron. A. Günther-schulze and Hans Betz. *Z. Physik* **114**, 82–91(1939).—

1 The rate of diffusion of electrolytically produced H atoms through Fe was detd. in the temp. range −40° to 50°. The diffusion coeff. in sq. cm./day is given by $D_e = 0.0193T - 5.66$, where T is the abs. temp. The diffusion coeff. for protons is practically const. in the range −66° to 22°. At liquid-air temps., Fe is not permeable to protons, presumably because the H atoms also present remain in the metal at that temp. and fill the holes, thus preventing the protons from moving. The fact that no
2 metal other than Fe shows proton diffusion is probably due to the low rate of diffusion of H atoms. E. J. R.

Building up of crystals. Ulrich Dehlinger. *Die Physik* **5**, 9–22(1937); *Neues Jahrb. Mineral. Geol.*, Ref. I, **1938**, 514.—An account of recent work with special reference to heteropolar and metallic linkages, distribution of foreign ions, mosaic and secondary structures and crystal plasticity. References. C. A. Silberrad

3 **The basicity of heteropolyacids, a structure problem.** O. Kraus. *Naturwissenschaften* **27**, 740(1939); cf. *Fortschr. Mineral. Krist. Petrog.* **21**, 63(1937).—In crystn. of iron silicotungstates an unknown salt, intensely yellow, tetragonal leaflets, 2–3 mm. diam., 0.5–1 mm. thick, was obtained. The crystals are combinations of (001) and (h01). The crystals are air stable, decompd. in cold water, optically pos., symmetry C_4. The lattice
4 consts. are $a = 12.18$, $c = 18.82$ A., $c/a = 1.5452$, translation group T_0, from the analysis $Fe_8HSi_2W_{24}O_{84}.52H_2O$ follows 1 mol. per cell, $d_{x\text{-ray}} = 4.19$. The cell corresponds in size and shape to that of the 30-H_2O acid $H_4SiW_{12}O_{40}$ with $a = 12.98$ and $c = 18.52$ A. (*C. A.* **30**, 1280[8]). The anomalous optical conduct is explained from a stress introduced by replacing more than 4 H atoms of the 8-basic acid $H_8SiW_{12}O_{42}.28H_2O$. It is likely that the cations have taken the place of some of the H_2O in the acid lattice.
5 It is concluded that the basicity of the heteropolyacids is essentially a space problem. B. J. C. van der Hoeven

Polymorphism of iodides of choline esters. Cécile Stora. *Compt. rend.* **210**, 107–9(1939); cf. Loury, *C. A.* **34**, 716[8].—X-ray examn. of the 2 forms of the iodides of the lauryl (I), palmityl (II) and stearyl (III) esters of choline shows the A form (tablets, slightly double refracting $\gamma - \alpha = 0.008 - 0.009$) to be monoclinic, space group $C_{2h}' - P_{2m}$, β 70°53′, with 4 mols. in
6 the unit cell. The B forms of all 3 (leaflets, strongly double refracting, $\gamma - \alpha = 0.035 - 0.039$) appear to be triclinic. The B form is less stable than the A, changing spontaneously thereinto, rapidly in the case of I, slowly in that of III, whereas no such change has so far been observed in II. Other crystallographic data are given. C. A. S.

The single-crystal x-ray diffraction pattern of calcite. Franklin Miller, Jr. *Phys. Rev.* **56**, 757–64(1939).—
7 The method of analysis of double spectrometer rocking curves developed by Smith (*C. A.* **29**, 42[3]) is reconsidered and allowance for a simple type of mosaic structure is made. The (1, −1) rocking curve of Mo $K\alpha_1$ from calcite predicted by the equations and that exptly. measured by L. G. Parratt (*Rev. Sci. Instruments* **6**, 387–99(1935)) are consistent as regards Fourier components of long period and large amplitude and hence show that the theory of the double spectrometer is not entirely wrong, but the
8 inconsistency of the short-period components is difficult to explain. A single-crystal pattern is deduced and indicates that the crystals used by Parratt do not have the flat-topped Darwin-Ewald-Prins diffraction pattern.
John T. Burwell

Chemistry of the "inert" gases. IV. Solid-solution formation between "inert" gases and other substances. B. A. Nikitin. *Compt. rend. acad. sci. U. R. S. S.* **24**, 562–4(1939)(in German); cf. *C. A.* **30**, 4755[9]; **34**, 685[3].—
9 When passed in the gaseous state into a tube contg. Rn under very low pressure and at temps. between −90° and −136°, HCl, H_2S, SO_2 and CO_2 form crystals which also contain considerable Rn, but NH_3 does not carry down any appreciable quantity of Rn. Crystals of HCl, HBr, H_2S, SO_2, CO_2 or Me_2CO at approx. −96° to −136° absorb Rn from the gaseous phase; very little Rn is absorbed by PhOH or $PhNH_2$ crystals at −130° and −110°, resp., in 2 hrs., whereas with NH_3 and H_2O crystals at

−110° (and −10° for the latter) practically no Rn is absorbed in 2 hrs. Crystals of NH_3 formed at −185° in the presence of A and Ne absorb practically none of the "inert" gases; at −140° to −185° HCl crystals formed in a similar manner contain practically no Ne and only a small amt. of A. Co-crystn. with HCl or H_2S is proposed as a quant. method for the sepn. of Rn from A and Ne. Retention of Rn in the crystal lattices of certain hydrides (such as HCl or H_2S) possibly depends on (1) the large size of the Rn atom and (2) the large dipole moment of the hydride. V. **Combination of radon with phenol.** *Ibid.* 565-7.—By analogy with substances of roughly similar phys. properties such as H_2S which forms an addn. compd. with PhOH (Terres and Vollmer, *C. A.* 29, 8302[4]), Rn could be expected to form a similar addn. compd. Powd. PhOH at −35° rapidly takes up H_2S; the reaction occurs at room temp. only after seeding with the addn. compd. The dissocn. pressures of $H_2S.2PhOH$ (I) are (mm. Hg, °C.): 108, −10°; 198, 0°; 440, 15°; 580, 20° and 760, 25.3°. Solid PhOH does not take up Rn directly, but isomorphous solid solns. of PhOH with H_2S and Rn can be prepd. by 3 methods: (1) repeated crystn. of I after exposure to air contg. Rn; (2) preliminary crystn. of H_2S with Rn and recrystn. of its PhOH addn. compd. at 15°; and (3) pptn. of I in the presence of Rn. The Berthelot-Nernst distribution const., D = [(percentage of Rn in crystals × percentage of H_2S in gas)/(percentage of Rn in gas × percentage of H_2S in crystals)], is a const. (1.19 − 1.30) within exptl. error for material prepd. by each of the 3 methods. It follows that $Rn.2PhOH$ was formed; the m. p. probably lies in the vicinity of 50°. Argon also forms solid solns. with I, with D = 0.002. SO_2, HCl and HBr form analogous addn. compds. in which log p is a linear function of temp., where p = dissocn. pressure. The dissocn. pressure of H_2S hydrate is 1 atm. at 3°. George Ayers

The crystal chemistry of intermetallic AB_2 compounds (Laves phases). Gustav E. R. Schulze. *Z. Elektrochem.* 45, 849–65(1939).—F. Laves' (cf. *C. A.* 29, 7146[6]; 34, 67[8]) investigation of the crystallography of alloys is reviewed. Laves phases are AB_2 intermetallic compds. whose structure and combination mechanism are detd. by the crystal lattice; they crystallize, for example, in the structures of $MgCu_2$, $MgNi_2$ and $MgZn_2$. In the discussion of the geometric properties of this lattice it is shown that the A atoms show a very high coördination no., 16, while the B atoms have a coördination number of 6; this indicates the metallic character of combination forces from the A atoms. The coördination ratios are shown to be very characteristic for the combination mechanism of the Laves phases. A comparison of the at. distances in Laves phases and in pure components show distance shortenings in the Laves phases. The B lattice is of greater importance than the A lattice. Thermodynamic considerations show that the energy of combination in the B partial lattice of a Laves phase is greater than the energy of combination of the B atom in elementary condition. The participation of the second outermost electron shell of the B atom in the compd. is responsible for this increase in energy of combination. A Laves phase occurs when an A atom with decided inclination to metallic combination meets with a B atom whose second outermost electron shell is not closed off and which has about 20% smaller radius. The structure, stoichiometry and order of proportion of the atoms of the Laves phases are explained on the basis of their combination mechanism. M. M.

Adsorption error in the determination of gaseous densities and the adsorption of gases on vitreous silica. G. A. R. Hartley, T. H. Henry and R. Whytlaw-Gray. *Trans. Faraday Soc.* 35, 1452–61(1939).—The gases CO_2, C_2H_4, N_2O, O_2, A, N_2, CO and SO_2 were adsorbed at 21° on a quartz bulb of internal surface 271 sq. cm. at pressures from 30 to 760 mm. The adsorption on clean surfaces is very small and a great deal less than adsorption on glass surfaces for the same gases. O_2 is adsorbed to the extent of 0.20 × 10^{-6} cc./sq. cm. at 760 mm. and 21°; A, 0.42 × 10^{-6}; CO, 0.44 × 10^{-6}; N_2, 0.74 × 10^{-6}; CO_2, 1.44 × 10^{-6}; C_2H_4, 1.51 × 10^{-6}; N_2O, 1.61 × 10^{-6}; SO_2, 11.0 × 10^{-6}. The probable errors produced by adsorption in the mol. wts. of gases detd. by means of the silica microbalance by the method of limiting pressures is found for SO_2 to be 1 part in 8000. This error can be corrected to yield a final accuracy in the mol. wt. of 1 part in 40,000. Victor R. Deitz

Thin protein membranes. O. Gatty and J. H. Schulman. *Trans. Faraday Soc.* 35, 1510–13(1939).—Stable protein multilayers can be stretched by the dipping technique across silk and across fine-mesh wire gauzes made from Cu of 30 μ mesh of wire 10 μ in diam. The resulting films are impermeable to isamine blue but sufficiently permeable to NaCl for 200 layers to hold a diffusion potential, different from that in the absence of the membrane, at a value which decays with a half life of 20 min. The diffusion const. of NaCl is lower in the membrane than in water and the partition coeff. leads to lower salt concns. in the membrane. Victor R. Deitz

Studies of solutions of hydrocinnamic acid and of lauryl sulfonic acid with the film balance. James W. McBain and Warren V. Spencer. *J. Am. Chem. Soc.* 62, 239–44 (1940).—Data are presented for film-balance expts. upon several specimens of hydrocinnamic acid, cinnamic acid and dodecylsulfonic acid with special reference to the long time periods necessary for recovery after sweeping and the formation of a semi-insol. pellicle upon suitable compression of certain surfaces. The results indicate that the various phenomena of surface pressure and of time frequency pass through a high max. in an intermediate range of dil. soln.; whether a pellicle forms or not depends on the concn. and the degree of compression of the surface. Some substances apparently never form it, but when a pellicle is formed and sufficiently compressed, the final pressure is characteristic only of the substances. A. B. Garrett

Surface tension in the PLAWM trough. J. W. McBain, J. R. Vinograd and D. A. Wilson. *J. Am. Chem. Soc.* 62, 244 8(1940); cf. *C. A.* 31, 2497[1].—The PLAWM trough was devised by replacing the superficial floating barrier of the Pockels-Langmuir-Adam surface film trough by a water-tight, flexible barrier made of vulcanized dipped latex rubber. This barrier was cemented to the bottom and walls of the trough and fastened to a float in the line of the surface. The trough was used to study film characteristics of solns. of hydrocinnamic acid, K laurate, Na butylbenzenesulfonate and laurylsulfonic acid. The data indicate that the surface tension of solns. of hydrocinnamic acid is not fully established until after periods of time enormously greater than expected from classical diffusion processes. The existence of Type III curves with a min. was critically established. In these a trace of solute reduces the surface tension of the solvent to a fraction of its value and further small addn. raises the surface tension again to a still low max. or const. value This was shown for laurylsulfonic acid and butylbenzenesulfonate. With K laurate addn. of alkali appears to lower the flat max. to the value of the min. A. B. G.

The influence of electrolytes on the balloelectric effect. P. H. Burdett, J. E. Magoffin and F. K. Cameron. *Textile Research* 10, 149–66(1940).—A study of the p. d. with reference to the gas-liquid interface formed by spraying a liquid into a gas from an atomizer. The app. used is considered successively under 5 headings: (*a*) the air supply, (*b*) the sprayer, (*c*) the tray, (*d*) the electrometer and (*e*) the slide, and the procedure is outlined. Balloelectricity is defined as a surface phenomenon and occurs only on the rupture of an interface. The phenomenon cannot be simply a sepn. effect between the components of the double layer because the net effect would then be zero, owing to the recombination of the neg. and pos. carriers on the collector. The orientation of solvent mols. in the surface must be involved. The addn. of electrolytes probably affects the orientation of dipoles in the surface and thus controls the balloelec. effect. Cations seem to have 2 effects: the more important is due to their size which affects the rate of change of potential with concn. and the other due to their elec. properties, affects the intercept of the P-log c curve. The anions seem to

have only one effect which is due to their size. Probably the mechanism of the phenomenon is a transference of electrons from the gas to the liquid and from the liquid to the gas as the case may be. Among the conclusions are: (1) it is possible to measure the p. d. between the ground and small droplets of water or aq. solns. sprayed from an atomizer, (2) the potential has a neg. sign for pure water, (3) very small amts. of electrolytes make the potential more neg. but slightly larger amts. reduce the neg. potential below the value for pure water, (4) if the potential is plotted against the log of the concn. of cation, a straight line is obtained, (5) the elec. properties of the cations have some effect which is not fully understood at present, (6) the mechanism of the phenomenon consists of the transfer of electrons between the liquid and gas phases, (7) the ion size is probably of significance in the coagulation and dispersion of colloidal systems by electrolytes and (8) the p. d. at the liquid-gas interface is too small to be of practical importance in textile mill waste treatment. Certain changes in the app. are suggested. Forty references. W. H. Boynton

Subsieve sizing analysis of finely divided minerals by elutriation or sedimentation. II. Kazuo Kanazawa. *Suiyokwai-Shi* **10**, 97–104(1939); cf. *C. A.* **32**, 4408[3].—The Wiegner-Gessner sedimentation app. does not fractionate, but gives only the distribution of the sizes. The distribution of the sizes is calcd. from the sedimentation curve which is automatically photographed on bromide paper wound on a rotating drum. This drum can be adjusted to make 1 revolution in 1 hr. or in 24 hrs. as circumstances demand. However, this app. can be applied in sizing analysis of mineral particles from 0.1 mm. downward, but is not so simple as the Andreasen pipet and the results cannot be checked under a microscope. Therefore it is suitable for testing the settling conditions through its sedimentation curve. H. Nishimura

Wettability of solid surfaces. Henri Devaux. *Compt. rend.* **210**, 27–9(1940); cf. *C. A.* **27**, 4983.—The phenomenon is described in detail, and the essential similarity of, e. g., a film of water on a new glass surface (as of a newly blown glass vessel) to a film of oil on water is emphasized. Its dependence on the nature of the surface, which may vary from point to point with the polarity of the mols. exposed at the point, is discussed. C. A. S.

Heat diffusion in clay and peat. N. A. Nasedkin and G. I. Pokrovskiĭ. *J. Tech. Phys.* (U. S. S. R.) **9**, 1515–26 (1939).—The distribution of water and temp. in a column of peat heated at one end was detd. In calcn. it was supposed that the air in peat is present as sep. bubbles the vol. of which depends on the temp. and the surface tension of the surrounding water. The theory is not supported by expts. J. J. Bikerman

Physical processes in the course of deformation of sand. G. I. Pokrovskiĭ. *J. Tech. Phys.* (U. S. S. R.) **9**, 644–53 (1939).—A cylinder was filled with sand, the air between the sand particles displaced by water, and the sand-water mixt. compressed by a piston permeable to water and impermeable to sand. The lowering of the total vol. ΔV was compared with the vol. Δv of the water that was squeezed out; the relative compression $(\Delta V - \Delta v)/\Delta V$ of sand was 0.05. In kerosene it was 0.04. It is concluded that the modulus of *elasticity* of sand is much less than that of quartz in bulk. When the sand runs through a metal funnel (tin, brass or iron) it acquires an elec. charge the magnitude of which decreases with increasing no. of runs. This *triboelec.* effect also shows that the surface of sand differs from its interior. J. J. Bikerman

Dialysis through cellulose membranes. Viktor Nowatke. *Roczniki Chem.* **19**, 135–41(1939).—The permeability of viscose cellulose membranes of the type of cellophane was detd. B. C. P. A.

Scattering of polarized light in colloids. R. S. Krishnan. *Proc. Indian Acad. Sci.* **10A**, 395–8(1939); cf. *C. A.* **32**, 4041[8].—For light scattered in the transverse horizontal direction $\rho_\theta = [1 + (\tan^2\theta)/(\rho_h)]/[\tan^2\theta + (1/\rho_v)]$. It is assumed that for large anisotropic particles the vol. scattering and the anisotropic scattering are uncorrelated. Detns. of ρ_θ made on graphite sol, As_2S_3 sol, and toluene emulsion to test this assumption give results significantly lower than the calcd. values. Graphite sol, which contains highly anisotropic particles, shows greater deviation than toluene emulsion, which contains isotropic droplets. Donald C. Bond

The binding of water in hydrates of manganese dioxide, titanium dioxide and thorium dioxide. Oskar Glemser. *Z. Elektrochem.* **45**, 820–9(1939).—The greater proportion of the H_2O in MnO_2, TiO_2 and ThO_2 hydrates is found to be loosely bound, the binding being capillary or osmotic (Hüttig's definition). The prepns. can be thought of as penetrated by canals of radius of about 100 A. The remainder of the H_2O is considered as bound in the interior of the colloid. H. C. Thomas

Freezing points of pure high polymers. Edwin L. Lovell and Harold Hibbert. *J. Am. Chem. Soc.* **62**, 230–1 (1940).—It is pointed out that the authors' formula (*C. A.* **33**, 6799[4]) for the setting points of the polymer homologous series of $HO(CH_2CH_2O)_nH$ is identical with that derived by Huggins (*C. A.* **34**, 707[1]); this agreement is important addnl. evidence for the purity (uniformity of chain length) of this series of synthetic polymers. C. J. West

Combination of gelatin with acids and bases. Leo Friedman, Karl Klemm and Frank K. Thompson. *J. Phys. Chem.* **43**, 1133–7(1939).—The literature on the acid and base-binding capacity of gelatin is reviewed and the values obtained by various investigators presented in tabular form. Acid and base-binding capacities were detd. by electrometric titration and by viscosity studies and compared with the values obtained in the literature. The combining capacity of gelatin with several different acids and bases was detd. and found to vary according to the acid or base used. The combination of gelatin with acids and bases apparently is not simply a combination of gelatin with the H or OH ions. L. Kolodny

Solubility of gases. II. Comparison of organic solvents with water. D. D. Eley. *Trans. Faraday Soc.* **35**, 1421–32(1939); cf. *C. A.* **34**, 925[5].—Using the data of Lannung (cf. *C. A.* **24**, 1565[6]) and of Valentiner (cf. *C. A.* **21**, 2210, 5574), the former for acetone, C_6H_6, ether, CCl_4, MeOAc, MeOH, EtOH and the latter for H_2O, the solubilities of He, H_2, N_2, NO, O_2, CH_4, CO_2, N_2O show that the partial molal vol. of a gas is smaller in water than in any of the org. solvents. The more neg. energy of soln. for H_2O is attributed to different energy required to form a cavity in the solvent. Similarly the difference between the entropies of soln. are considered to arise from a difference in the entropies of cavity formation. V. R. D.

The solubility of calcium oxalate in various salt solutions. H. Shehyn and D. B. Pall. *J. Phys. Chem.* **44**, 166–71(1940).—The soly. of $Ca(C_2O_4)_2$ was detd. in solns. of Na_2SO_4, NH_4Cl and $(NH_4)_2SO_4$ at room temp. (27.5, 28 or 30°), at 50° and at 95° and in a soln. of NH_4NO_3 at 27.5°. A regular rise in soly. at a given temp. (28°) was noticed as the ionic strength increased from 0.01 to 0.20. This result agreed with outside data for the soly. in solns. of NaCl. H. S. v. Klooster

The solubilities of certain inorganic compounds in ordinary water and in deuterium water. Robert D. Eddy and Alan W. C. Menzies. *J. Phys. Chem.* **44**, 207–35(1940).—By use of the method of Menzies (cf. *C. A.* **30**, 5863[8]) the soly. in H_2O and in D_2O of NaBr, NaI, Na_2SO_4, KBr, $BaCl_2$, CdI_2 and $HgCl_2$ at temps. ranging from 0° to 105–180° was detd. with an accuracy of 1%. The limits of existence for the various salts and their hydrates and deuterates were located and the transition temps. of 6 hydrates and analogous deuterates compared. These incongruent m. ps. were sometimes lower and sometimes higher for deuterates than for the corresponding hydrates. The molar solubilities were recorded for rounded temps. at intervals of 5°. One metastable new hydrate and deuterate was discovered but its exact compn. could not be ascertained. H. S. v. Klooster

Hydrogen bonds involving the C–H link. IX. Nitriles and dinitriles as solvents for hydrogen-containing halogenated methanes. M. J. Copley, G. F. Zellhoefer and C. S. Marvel. *J. Am. Chem. Soc.* **62**, 227–8(1940); cf.

C. A. **34**, 978[1].—Soly. data are given for CH_2Cl_2 (I) and $CHCl_2F$ (II) in $Me(CH_2)_6CN$, PhCN, $(CH_2)_2(CN)_2$ (III), $(CH_2)_3(CN)_2$ (IV), $(CH_2)_4(CN)_2$ (V) and $(CH_2)_5(CN)_2$ (VI). III and IV dissolve less than the calcd. amt. of I and II; V dissolves almost the exact calcd. amt. and VI takes up more than the calcd. amt. This evidence for H-bond assocn. in the dinitriles is of interest in view of the recent estn. that HCN is similarly assocd. to the extent of 3% at the b. p. (*C. A.* **33**, 9110[2]). C. J. West

Partial vapor pressures from nicotine solutions at 25°. L. B. Norton, C. R. Bigelow and W. B. Vincent. *J. Am. Chem. Soc.* **62**, 261–4(1940).—The partial vapor pressures of nicotine and water in all binary solns. at 25° were detd. by the dynamic gas-satn. method. The deviations from Raoult's law are very large and in the direction of higher vapor pressure of both components. The results agree with the Duhem equation, $d \ln P_1/d \ln x = d \ln P_2/d \ln (1-x)$. The activity coeffs. of nicotine in dil. soln. decrease very rapidly with increasing concn. With increasing percentages of nicotine, the loss of nicotine relative to that of water first increases rapidly, then remains nearly const. over a long range, and finally increases very rapidly during free evapn. A. B. Garrett

Ebullioscopic investigations of solutions of azides and cyanides in hydrogen fluoride. Willi Klatt. *Z. physik. Chem.* **A185**, 306–12(1939); cf. *C. A.* **31**, 8259[7].—The molal b.-p. rise of solns. of AgN_3 in HF indicates the formation of 4 ions per mol.; that for HgN_6 indicates 3. Formation of $AgFH^+$, HN_3H^+ and 2 F^- in the first reaction and of $HgN_6H_2^+$ and 2 F^- in the second is postulated. PbN_6 produces a ppt. of insol. PbF_2 with evolution of gaseous HN_3. Alk. cyanides are decompd. by HF with the evolution of HCN. $Hg(CN)_2$ dissolves and produces a b.-p. rise approx. twice the molal rise. A table is included showing the action of HF on the fluorides, chlorides, cyanides and azides of 24 metals. T. H. D.

Apparent molal volumes of strong electrolytes in aqueous solutions. M. K. Srinivasan and B. Prasad. *Trans. Faraday Soc.* **35**, 1462–5(1939).—The ds. of aq. solns. of $NaNO_3$, NaCl, KNO_3 and KCl were measured at 35° ± 0.005°. The apparent molal vols., ϕ, in cc. are given as follows for the above salts, where c = d. in g./cc.: $\phi(NaNO_3) = 30.30 + 1.27\sqrt{c}$; $\phi(NaCl) = 18.10 + 1.24\sqrt{c}$; $\phi(KNO_3) = 40.80 + 0.96\sqrt{c}$; $\phi(KCl) = 28.40 + 1.5\sqrt{c}$. The ds. are tabulated from 0.001 to 1.0 with an accuracy of 9 parts in a million. Victor R. Deitz

Study of surface and interfacial tensions of solutions of the cyanines. Maurice Aubry. *J. chim. phys.* **36**, 263–70(1939); cf. *C. A.* **33**, 6677[8].—Measurements were made of the variation of the surface tension and the interfacial tension of aq. solns. of a color indicator (methyl bromide-2,2-diethyl thiocarbocyanine). Surface tension falls regularly as a function of the concn. and as a function of the temp. The interfacial tension is measured in contact with pure CCl_4. It falls very rapidly. This falling or lowering as a function of concn. is of the form $\Delta\gamma = BC^n$. The interpretation of this phenomenon is based on the hypothesis of a hydrophilic and a hydrophobic side of the colored mol. It is the hydrophobic side which would be oriented in the direction of the surface of CCl_4. The hydrophilic side is directed toward the water. The measure of interfacial tensions could be utilized as a rapid method of detg. the coloring material. This method will be utilized for the study of adsorption of color indicators by the Ag halides. R. K. Carleton

Viscosity and density of aqueous solutions of barium chloride, magnesium chloride, cobalt chloride and nickel chloride at 35°. A. S. Chakravarti and B. Prasad. *Trans. Faraday Soc.* **35**, 1466–71(1939).—The viscosity of all the solns. studied obeys the Jones and Dole equation: $\eta/\eta_0 = 1 + A\sqrt{c} + Bc$ (*C. A.* **23**, 5375). The calcd. values of A (0.015, 0.017, 0.018) for $BaCl_2$, $MgCl_2$ and $CoCl_2$ agree with the exptl. values (0.018, 0.017, 0.018); for $NiCl_2$ the calcd. value is 0.018; exptl. 0.028. The B values are 0.285, 0.370, 0.370 and 0.316, resp. The apparent molal vols., ϕ, are linear functions of $\sqrt{c}$, for concns. greater than 0.025 mol./l.: $\phi(BaCl_2) = 28.2 + 5.5\sqrt{c}$; $\phi(MgCl_2) = 15.0 + 6.0\sqrt{c}$; $\phi(CoCl_2) = 16.0 + 4.2\sqrt{c}$; $\phi(NiCl_2) = 10.0 + 9.6\sqrt{c}$. The max. error in the tabulated ds. is 16 parts per million. Victor R. Deitz

The viscosity of solutions of electrolytes as a function of the concentration. VI. Potassium bromide and lanthanum chloride. Grinnell Jones and Robert E. Stauffer. *J. Am. Chem. Soc.* **62**, 335–7(1940); cf. *C. A.* **33**, 3633[3].—The abs. ds. and relative viscosities of many solns. of KBr were detd. at 0° and of solns. of $LaCl_3$ at 25 and 0°. The results confirm the Root equation (cf. *C. A.* **27**, 1562) for ds., the Jones and Dole equation (cf. *C. A.* **23**, 5375) for viscosities and the Falkenhagen and Vernon equation for the effect of the interionic attraction on viscosity. **VII. Silver nitrate, potassium sulfate and potassium chromate.** Grinnell Jones and John H. Colvin. *J. Am. Chem. Soc.* **62**, 338–40(1940).—The abs. ds. and the relative viscosities of many solns. of $AgNO_3$, K_2SO_4 and K_2CrO_4 were detd. at 0° and 25°. The results confirm the Root equation (cf. *C. A.* **27**, 1562) for ds., the Jones and Dole equation (cf. *C. A.* **23**, 5375) for the viscosities and the Falkenhagen and Vernon equation for the effect for interionic attraction on the viscosity. The results do not confirm Simon's proposed law (cf. *C. A.* **18**, 2452) that isomorphous substances have the same effect on viscosity. A. B. Garrett

The conductance of solutions or organosubstituted ammonium chlorides in liquid hydrogen sulfide. E. E. Lincken and J. A. Wilkinson. *J. Am. Chem. Soc.* **62**, 251–6(1940).—These data duplicate earlier measurements (cf. *C. A.* **19**, 1519) using modern bridge technique (cf. *C. A.* **22**, 1892; **24**, 3181) and extend the concn. range as well as the no. of compds. studied to include solns. of mono-, di-, tri- and tetra-substituted Me-, Et- and Pr-NH_4 chlorides. The data indicate that the mol. cond. increases both with the no. and the size of the substituted groups, the no. having a greater effect than the size. The cond. concn. curves show a min. which is characteristic of solns. of electrolytes in solvents of low dielec. const. (cf. *C. A.* **27**, 5233). An app. for the prepn., purification and liquefaction of H_2S is described. A. B. Garrett

Dissociation constants and titration exponents of several less common alkaloids. N. Schoorl. *Pharm. Weekblad* **76**, 1497–1501(1939).—By the method of Kolthoff (*C. A.* **20**, 561; *Biochem. Z.* **162**, 289–353(1925)) the dissocn. consts. of several alkaloids were detd. colorimetrically. Solns. of 0.01 *N* salts were titrated with 0.01 *N* NaOH, temp. 23°, pH + pOH = 14. For monobasic alkaloids: dicodide-HCl (equiv. wt. 384) (probably with 2.5 H_2O) pK = 6.05, dilaudide-HCl (321.6) pK = 6.2, β-eucaine-HCl (283.5) pK = 4.65, eucodal-HCl (405.5) pK = 5.4, heroine-HCl (405.4) pK = 6.4, homatropine-HBr (356) pK = 4.3, scopolamine-HCl (H_2O) (375.5) pK = 6.5, stovaine-HCl (271.6) pK = 6.1. For dibasic alkaloids: alypine-HCl (314.4) $pK_1 = 4.5$, $pK_2 = 10.2$, optochine-HCl (376.4) $pK_1 = 5.5$, $pK_2 = 9.95$, yohimbine-HCl (390.4) $pK_1 = 6.55$, $pK_2 = 11$. Calcd. titration exponents for titration in 0.1 or 0.01 *N* soln. are given for all (54) alkaloids, including those previously studied by Kolthoff. B. J. C. van der Hoeven

Dissociation of carbonic acid in ordinary and in heavy water. G. Alexander Mills. *J. Am. Chem. Soc.* **62**, 449 (1940).—The ratio of the apparent 1st dissocn. consts. of proto- and deuterocarbonic acids is 2.68 at 25° (Rule and La Mer, *C. A.* **32**, 7328[2]); the predicted value is 3.6. In conjunction with cond. data the true dissocn. const. was estd. to be $4 \times 10^{-4.3}$. From the smooth plot of $-\log K^H$ against K^H/K^D the value of 2.9 is obtained for this ratio, which compares more favorably with 2.68 than the predicted value of 3.6. C. J. West

Activity coefficients in concentrated aqueous solutions of strong electrolytes described by means of a formula containing the mean ionic diameter as single parameter. II. Corrected formulation. Pierre Van Rysselberghe and Sylvan Eisenberg. *J. Am. Chem. Soc.* **62**, 451–2(1940); cf. *C. A.* **34**, 3084.—By use of a corrected formula the following values were calcd. for the ionic diam. in the range of concns. 0.1 to 3 *M*: LiCl 3.82, LiBr 3.93, LiI 4.29, NaCl 3.31, NaBr 3.53, NaI 3.69, KCl 2.93, KBr 3.02,

KI 3.22, RbCl 2.72, RbBr 2.71, RbI 2.64, CsCl 2.42, CsBr 2.36 and CsI 2.17. C. J. West

Ionization constants of acid-base indicators in ethanol. L. S. Guss and I. M. Kolthoff. *J. Am. Chem. Soc.* **62**, 249–51(1940).—These data are used to correct earlier data (cf. *C. A.* **25**, 5824) in terms of relations indicated by the limiting law and to consider the effect of varying ionic strength on some indicator-buffer equilibria. The behavior of acid-base indicators in ethanol is much the same as in methanol. At infinite dilns., the curves approach the slope of 5.8 required by the Debye-Hückel limiting law. At higher salt concns., the ionic diam. and individual mol. characteristics bring about variations that are to be expected. Thermodynamic ionization consts. of a no. of indicators were measured. A. B. Garrett

The reduction equilibrium of chromic oxide. G. Grube and M. Flad. *Z. Elektrochem.* **45**, 835–7(1939).—By equilibration of Cr_2O_3 in streams of H_2O vapor and H_2, analysis of the solid and calcn. of the O_2 partial pressure from the known dissocn. of steam, the equil. of the reaction $2\ Cr + {}^3/_2\ O_2 \rightleftharpoons Cr_2O_3$ was detd. The O_2 pressures are 7.4×10^{-25}, 5.1×10^{-23}, and 3.8×10^{-22} atm. at 895°, 968°, 1002°, resp. The heat of reaction between 895° and 968° was found to be 252.4 kg.-cal.; between 968° and 1002°, 279.7 kg.-cal. H. C. Thomas

The equilibrium FeO + H_2 ⇌ Fe + H_2O at temperatures up to the melting point of iron. John Chipman and Shadburn Marshall. *J. Am. Chem. Soc.* **62**, 299–305 (1940).—The data established the equil. conditions involving steam, H, solid iron, and liquid oxide over a sufficient range, 1200–1515°, to permit extrapolation to the m. p. of iron. Below the m. p. of the oxide the new results and those of Emmett and Shultz (cf. *C. A.* **26**, 5249) are expressed by an equation which agrees essentially with the data of Jominy and Murphy (cf. *C. A.* **25**, 2629). Above the m. p. the value of $K = P_{H_2O}/P_{H_2}$ is given by $\log K = 1583/T - 1.021$. The m. p. of the equil. oxide was found to be 1369° and the heat of fusion 10,000 cal. per mol. The m. p. of O-free and O-satd. iron was found to be, resp., 1535° and 1524°. A. B. Garrett

Relative oxidation potentials of ketones. Fred W. Cox and Homer Adkins. *J. Am. Chem. Soc.* **61**, 3364–70 (1939).—Thirteen representative ketones were compared with each other as oxidizing agents. This was done by equilibrating 2 ketones against each other in the presence of (*tert*-BuO)$_3$Al and the alcs. corresponding to the ketones. The concn. of the ketones at equil. was detd. by means of a polarograph. For purposes of comparison the value of 1 is assigned to iso-Pr_2CO; all the other ketones studied, with possibly 1 exception, are stronger oxidizing agents than the standard; other values are: Bu_2CO 0.97, Pr_2CO 0.95, iso-Bu_2CO 0.93, Et_2CO 0.68, *tert*-BuCOPh 0.64, PrCOPh 0.62, BuCOPh 0.55, AmCOPh 0.52, EtCOPh 0.51, iso-PrCOPh 0.39, Ph_2CO 0.32, cyclohexanone 0.19. In general, there is a parallelism between the depolarization or "reduction" potential as measured on the polarograph and the strength of a ketone as an oxidizing agent as detd. by equilibration. The aliphatic ketones have a high depolarization potential and a low oxidation potential, whereas the quinones have a very low depolarization potential, and a high oxidation potential. However, the depolarization potential cannot be safely used as a guide in predicting the strength of a ketone as an oxidizing agent. The oxidation potential of a ketone cannot be considered apart from the reducing power of the alc. corresponding to it. C. J. West

Experiments with atomic hydrogen: a search for higher hydrides of nitrogen, phosphorus and sulfur. K. G. Denbigh. *Trans. Faraday Soc.* **35**, 1432–5(1939).—NH_3, PH_3 and H_2S were brought into contact with at. H in an attempt to prep. higher hydrides, corresponding to PF_5 and SF_6. All 3 gases caused H atoms to recombine; PH_3 and H_2S were in addn. decompd. The reaction products, condensed in liquid air, were then analyzed by thermal decompn. at const. vol. Changes in the reactant gases were noted by detg. the pressure increases; higher hydrides would have caused greater pressure increases. No evidence of higher hydride formation was detected. A case of poisoning of a Pt spiral in catalysis of H atom recombination was noted at a point where Pt was exposed to stopcock grease. Victor R. Deitz

The region of validity of the Arrhenius [reaction velocity] relation for reactions in solutions. Walter Hückel, Irmgard Schneider and Willy Doll. *Z. physik. Chem.* **A185**, 313–20(1939).—Below 60° the Arrhenius relation does not apply to the sapon. of acid cyclohexylphthalate with KOH and of *cis-o*-methylcyclohexylphthalate with NaOH. Above 60° the expression applies satisfactorily to these cases. For the sapon. with KOH of acid cyclohexylphthalate and of *trans-o*-methylcyclohexylphthalate the relation is satisfactory from 40° to 90°. The presence of colloidal particles of alkali salts in the solns. at low temps. is suggested as a possible cause of the discrepancies. T. H. Dunkelberger

Exchange of bromine-ions between silver bromide and a bromine solution. A. Polesitskiĭ. *Compt. rend. acad. sci. U. R. S. S.* **24**, 668(1939)(in English).—A repetition of expts. reported in a former paper (cf. *C. A.* **33**, 3654[4]) attempting to prove that a full exchange of Br ions between freshly coagulated AgBr and KBr soln. takes place in a few min. One g. AgBr was mixed with equiv. amts. of $AgNO_3$ and KBr, coagulated by stirring, filtered off and treated with 10 cc. KBr soln. One of the components (AgBr or KBr) contained radioactive Br. The activity, measured at intervals with a Geiger-Müller counter, gave the degree of exchange. The exchange was found to proceed very rapidly at first (10% exchange in the first min.) then the ratio dropped abruptly, requiring 20 to 30 hrs. to reach completion. This is attributed to aging of the ppt. "Preaged" ppts. were found to have slower rates of exchange, and melted AgBr showed no exchange. Frank Gonet

Investigation of intersolvate exchange of bromine ions in various solvents. S. Z. Roginskiĭ and V. E. Tartakovskaya. *Compt. rend. acad. sci. U. R. S. S.* **24**, 709–11 (1939)(in English).—Radioactive halogens were used as indicators in studying the pptn. of Ag halide salts from aq.-alc. solns.; an unequal rate of pptn. of the halogen ions was found. The conditions necessary for the effect to appear are (1) slowness of intersolvate exchange, (2) presence of substances that react in different ways with solvate ions of the 2 different types, (3) slowness of the isotopic exchange between the products of (2) and the initial substance in soln. The effect of the lag in intersolvate exchange was observed in the following systems: (*a*) EtOH-water, (*b*) acetone-water, (*c*) glycerol-water, (*d*) glycerol-acetone and (*e*) MeOH-water. Pos. effects were also reported in the pptn. of a soln. of Hg_2^{++} ions. The effect has a purely kinetic character (the velocity differs from system to system) and disappears if the soln. is kept at room temp. for a long period of time. The period was found to be shortened by raising the temp. or by the addn. of acid. The authors believe that the magnitude and the stability of the effect point to an existence of solvates contg. mols. of only one of the solvents in the envelope surrounding the ions. Frank Gonet

The exchange reaction of the nuclear hydrogen atoms of phenol. II. The exchange reaction in acid solution. Masao Koizumi. *Bull. Chem. Soc. Japan* **14**, 353–62 (1939); cf. *C. A.* **33**, 2399[4].—The reaction $C_6H_5OH + HDO = C_6H_4DOH + H_2O$ was studied at 4 temps. between 90 and 120° with various concns. of HCl. The reaction is of the 1.26 order with respect to the H-ion concn., this unexpected order being due to an increase in the collision factor with acid concn. The activation energy was detd. as 27.3 kg.-cal. A mechanism is suggested to account for the fact that the activation energy is higher in acid than in alk. soln. John E. Vance

The kinetics of saponification of methyl acetate in dioxane-water mixtures at 25°. Tzu-Ching Huang and Ho-Sheng Hsieh. *J. Chinese Chem. Soc.* **7**, 1–13(1939). —The cond. method was used to measure the velocity of hydrolysis at 25° of 0.01 *N* AcOMe by 0.01 *N* NaOH in 0 to 30% mixts. of dioxane in water. The bimol. velocity const. increases with the amt. of dioxane present, accord-

ing to the equation: $k = 69x + 11.8$, where x is the mol. fraction of dioxane. Wm. H. Adolph

The kinetics of the thermal decompositions of the lower paraffins. V. The nitric oxide inhibited decomposition of butane. E. W. R. Steacie and H. O. Folkins. *Can. J. Research* **18, B**, 1–11(1940); cf. *C. A.* **33**, 4855⁸.—The inhibition by NO of the thermal decompn. of C_4H_{10} was studied in detail over the temp. range 500° to 550°. In all cases inhibition decreased with increasing C_4H_{10} concn. This suggests that radical recombination occurs in the normal decompn. by ternary collisions with C_4H_{10} mols. acting as third bodies. The activation energies of the normal and inhibited reactions were detd. For high pressures the 2 values agree well, viz., 58,200 and 57,200 cal. per mol., resp. The products of the inhibited reaction were also found to be the same as those of the normal reaction. Conclusion: Free-radical processes predominate, involving comparatively short chains. J. W. Shipley

The catalytic decomposition of azodicarbonate ion. Cecil V. King. *J. Am. Chem. Soc.* **62**, 379–85(1940).—The decompn. of azodicarbonate ion to give N_2, N_2H_4 and CO_2 or carbonate ion was found extremely sensitive to general acid catalysis. Data were obtained for catalysis by H^+ ion (in NaOH solns.), water, AcOH, NH_4 ion, acetoxime, maltose and sucrose; data are also given on the salt effect. The decompn. of the azodicarbonate ion is catalyzed by H_2O, H^+ ion and other acids in accordance with the equation $dx/dt = C_{N_2(COO)_2^{--}}(k_1C_{H_3O^+} + k_2C_{H_2O} + k_3C_{HA} + \ldots)$. The fact that catalysis by sucrose is diminished by bases is recognized as evidence that the above equation does not completely explain the mechanism of the reaction. The molar catalysis consts., as evaluated, agree well with the Brönsted equation $k_m/p = G(q/pK_A^\circ)^x$ where $G = 7.40 \times 10^8$ and $x = 0.86$. This value of G is the highest yet found for acid catalysis while the value of x is similar to that found in several other cases. A. B. Garrett

Calculation of the intermediate equilibria in catalytic kinetics and the geometry situs. A. A. Balandin. *Compt. rend. acad. sci. U. R. S. S.* **24**, 741–7(1939)(in English).—Math. General expressions are given in terms of equil. consts. for the equil. concns. in systems of any no. of components involving any given intermediate states. A. O. Allen

Amphoteric metal hydroxides as mono- and poly-component catalysts, in the role of inorganic enzymes. XLIX. Alfons Krause. *Roczniki Chem.* **19**, 129–34 (1939); cf. *C. A.* **33**, 1231⁷.—Hydrated CuO added to amorphous $Fe(OH)_3$-$Mg(OH)_2$ mixt., prepd. by simultaneous pptn., gives a highly active catalyst (Fe:Mg:Cu = 1:0.06:0.17) for the reaction $HCO_2H + 2H_2O_2 \rightarrow CO_2 + 2H_2O$, at 20°. The reaction mechanism is discussed. B. C. P. A.

The catalytic action of silver. Dino Dinelli. *Ann. chim. applicata* **29**, 448–51(1939).—Cu_2O pptd. from a soln. of $CuSO_4$ contg. traces of $AgNO_3$ is capable of catalyzing the oxidation of aldehydes to acid just as Ag_2O would. Cu_2O from a soln. free of $AgNO_3$ has no such ability. The reaction was checked with the oxidation of furfurole to pyromucic acid and BzH to benzoic acid. Both reactions give about 92% yields. A. W. C.

Measurements of the reaction velocity of hydrogen and oxygen at the surface of a platinum catalyst. E. F. M. van der Held and H. P. Reindl. *Physica* **6**, 997–1008 (1939).—The rate of combination of H_2 and O_2 on an electrically heated Pt wire was found proportional to PH_2 and to $(PO_2)^{1/2}$. The expts. were made at a total pressure of about 1 atm., N_2 being used as a diluent. P. H. E.

Equilibrium diagram of the nickel-rich nickel-beryllium system. Masazō Okamoto. *Nippon Kinzoku Gakkai-Si* **3**, 444–8(1939).—The equil. diagram of Ni-Be alloys on the Ni side was detd.; it coincides well with that given by Masing-Dahl (cf. *C. A.* **24**, 2410). The solid-soly. of Be in α-phase is 2.8% at 1100°, 2.6% at 1000°, 2% at 900°, and less than 1% at room temp. The Curie point of solid soln. satd. with Be is 255°, and the supersatd. α with 2.7% Be shows the Curie point at about 90°. The β-phase is a solid soln. corresponding to NiBe, and the solid-soly. of Ni decreases from higher to lower temp. H. Nishimura

Behavior of pyridine in binary systems with certain phenols and ketones. K. Hrynakowski and H. Ellert. *Roczniki Chem.* **19**, 156–66(1939).—The fusion diagrams suggest formation of *2:1 compds.* in the systems: C_5H_5N–*o*-, m. 17°, –*m*-, and –*p*-$C_6H_4(OH)_2$, transition point (t. p.) 33°, and –*m*-$NH_2C_6H_4OH$, m. –9°, and *1:1 compds.* in the systems C_5H_5N–*p*-$C_6H_4(OH)_2$, m. 78.2°, and –1,2,3-$C_6H_3(OH)_3$, t. p. 44.5°. Compds. are not formed in the systems C_5H_5N–*o*-$C_6H_4(OMe)_2$, –*o*-$NH_2C_6H_4OH$, –CHPh:CHCOMe, –benzil, and –COPhMe. B. C. P. A.

The system silver sulfate–aluminum sulfate–water. J. A. Addlestone, L. R. Marsh and G. C. Hall. *J. Phys. Chem.* **44**, 256–9(1940).—The 0°, 25° and 45° isotherms of the ternary system Ag_2SO_4–$Al_2(SO_4)_3$–H_2O were detd. The only stable solid phases are Ag_2SO_4 and $Al_2(SO_4)_3$·$18H_2O$. H. S. v. K.

A new method of isothermic calorimetry. G. Karagunis and G. Coumoulos. *Chim. Chronika* **10–12**, 215–17 (1938)(in Greek).—The method is based on the fact that substances with dipole moments produce sudden changes in the dielec. consts. upon fusion. By detg. the capacity change produced on heating a mixt. of the solid-liquid phase of a material at the m. p., the added heat is estd. By proper choice of dipole substances varying isothermic temps. can be produced. L. Y. Dyrenforth

Heat capacity of iron carbide from 68° to 298°K. and the thermodynamic properties of iron carbide. Harry Seltz, Hugh J. McDonald and Cyril Wells. *Am. Inst. Mining Met. Engrs., Tech. Pub.* No. **1137**, 11 pp.(1939). The heat capacities of Fe_3C were detd. experimentally from 68° to 298.1°K. The entropy was calcd. $S_{298.1} = 25.7(\pm 1)$ e. u. From the soly. curves of Wells for C and Fe_3C (β) in austenite the free energy and heat of formation of carbide are evaluated. At 298.1°K., $\Delta H = 5800$ cal., $\Delta F^\circ = 4700$ cal. for the formation of Fe_3C (α) and $S_{298.1} = 24.7$ e. u. The temp. at which $\Delta F^\circ = 0$ for $3Fe(\gamma) + C(\text{graph.}) = Fe_3C(\beta)$ is 1082°K Alden H. Emery

Thermal data. XI. The heat capacities and entropies of guanidine carbonate, glutamic acid hydrochloride, ornithine dihydrochloride, *d*-lactic acid and *l*-lactic acid. Hugh M. Huffman, Emory L. Ellis and Henry Borsook. *J. Am. Chem. Soc.* **62**, 297–9(1940).—The heat-capacity data were detd. between 90 and 298.1°K. The values of $S_{298.1}$ are: guanidine carbonate 70.59, glutamic acid hydrochloride 59.33, ornithine dihydrochloride 70.25, *d*-(*l*+)-lactic acid 34.30 and *l*(*d*−)-lactic acid 34.00. A preliminary value for the heat of fusion of *d*(*l*+)-lactic acid was found to be 4030 cal. per mol. A. B. Garrett

The heat capacities, heats of transition and fusion, and entropies of ethylene dichloride and ethylene dibromide. Kenneth S. Pitzer. *J. Am. Chem. Soc.* **62**, 331–5(1940).—The data were obtained from 15°K. to room temp. The following m. ps. (0°C. = 273.10°K.) and heats of fusion were detd.: $C_2H_4Cl_2$, 237.2 ± 0.1°K., 2112.0 ± 2 cal./mol.; $C_2H_4Br_2$, 283.0 ± 0.2°K., 2615.8 ± 5.0 cal./mol. The following temp. and heat of transition values were detd.: $C_2H_4Br_2$, 249.54 ± 0.10°K., 463.8 ± 2.0 cal./mol. From these data, the following values of entropy at 298.1°K. were calcd.: $C_2H_4Cl_2$(l), 49.84 ± 0.15 cal./degree mol.; $C_2H_4Br_2$(l), 53.37 ± 0.20 cal./degree mol. Ethylene dichloride shows no sharp transition but has a peak in the heat-capacity curve near 177°K. which may correspond partially to the transition in ethylene bromide. Since measurements of the dielec. const. (cf. *C. A.* **31**, 6943¹) show only small changes in passing through these regions, and since the difference in these transitions seems very great for 2 such similar compds., it is proposed that the coöperative or coupling effect between the rotation of 1 mol. and its neighbors may be relatively small. This would explain the whole curve for the chloride; the gradual rise in the bromide curve from 150° to 250°K. is also to be expected. Above 250°K. some fundamentally different crystal structure, based on rotating mols., may become more stable for the C_2H_4-

Br_2 thus giving rise to the sharp interphase transition. A. B. Garrett

The heat of formation of aluminum oxide (corundum) and of lanthanum oxide. W. A. Roth, Ursula Wolf and Olga Fritz. *Z. Elektrochem.* **46**, 42–5(1940).—By use of highly purified Al and improved technique, the molal heat of formation of Al_2O_3 (corundum) was detd. to be 402.9 ± 0.3 kg.-cal. at 22° and const. pressure, and that of La_2O_3 to be 539 ± 4 kg.-cal. La_2O_3 appears in at least 2 modifications, the one having the larger mol. vol. being stable at the lower temps. From the new value for Al_2O_3 the heat of formation of Al_4C_3 is recalcd. to be 50 ± 3 kg.-cal./mol. N. Bekkedahl

The heat of formation of chromic oxide. W. A. Roth and U. Wolf. *Z. Elektrochem.* **46**, 45–6(1940).—The heat of formation of Cr_2O_3 was detd. to be 268.9 ± 0.6 kg.-cal./mol. at 21° and const. pressure. From this value the heat of formation of CrO_3 was calcd. to be 137.1 ± 0.4 kg.-cal./mol. at 20° and const. pressure. N. Bekkedahl

The surface energy of cadmium oxide and the heat of formation of cadmium hydroxide. R. Fricke and F. Blaschke. *Z. Elektrochem.* **46**, 46–9(1940).—From $Cd(OH)_2$ crystals 2 different prepns. of CdO were made: (1) by heating 2 hrs. at 800° and (2) by heating 3 hrs. at 350°. The former prepn. was blue-black in color, whereas the latter was greenish yellow. The heats of soln. of the compds. were detd. to be 28.72 kg.-cal./mol. for $Cd(OH)_2$, 34.02 for the 350° prepn. of CdO, and 33.46 for the 800° prepn. of CdO. X-ray investigations found the mean particle sizes to be 190 and 2500 A. for the 350° and the 800° prepns., resp. From the differences of 0.56 kg.-cal. in molal heat contents and about 4700 sq. m. in molal surface areas between the 2 forms of CdO, the total molal surface energy of CdO is calcd. to be about 500 ergs/sq. cm. The heat of formation of $Cd(OH)_2$ from CdO and liquid H_2O is calcd. to be 5.30 and 4.74 kg.-cal./mol. for the 350° and the 800° prepns., resp. N. Bekkedahl

Thermal equilibrium between columbium pentoxide and carbon. Pierre Sue. *J. chim. phys.* **36**, 280–2(1939); cf. *C. A.* **33**, 4497[1]. —The equil. between Cb_2O_5 and C permits the calcn. of the heat of formation of the tetroxide. The value obtained in this work confirms a result obtained before in the equil. between Cb tetroxide and the vapor of water. The equil. used in the studies were: $Cb_2O_4 + H_2O \rightleftarrows Cb_2O_5 + H_2 + 18.2$ kg.-cal.; $Cb_2O_5 + C \rightleftarrows Cb_2O_4 + CO - Q_2$; $2CO \rightleftarrows CO_2 + C + 39$ kg.-cal.; $Cb_2O_5 + CO \rightleftarrows Cb_2O_4 + CO_2 - Q_4$. The system is considered to be composed of: Cb_2O_5, Cb_2O_4, CO_2, CO and C; it comprises 3 constituents and 4 phases. It is univariant.

$$K_4 = \frac{p^2CO}{pCO_2} = \frac{X^2}{P - X}$$

The mean of the values for the heat of reaction is 44 kg.-cal. A part of the heat of formation of Cb_2O_5 and of CO equals 463 and 26.4 kg.-cal. The heat of formation of the tetroxide is: 463.1 − (44 + 26.4) = 393 kg.-cal. In the work on the equil. between Cb_2O_4 and H_2O, the value found was 387 kg.-cal. R. K. Carleton

The coefficient of compressibility of liquids. P. Guareschi. *Atti accad. Lincei, Classe sci. fis., mat. nat.* **29**, 61–9 (1939).—G. has previously shown that the frequency of characteristic at. or mol. vibration can be expressed as follows: $\nu_0 = (1/\pi\sigma)\sqrt{H\nu/2\alpha m}$, where σ = mol. diam., α = coeff. of assocn. Einstein's formula for the characteristic mol. frequency of a solid can be expressed as $\nu_0 = CN^{-1/3}\ V^{1/6}/M^{1/2}K^{1/2}$, where V = at. or mol. vol., C = a const. whose value is about 0.25, M = at. or mol. wt., K = coeff. of compressibility of the fluid. From these equations, which are equal, the value of K can be calcd. $K = 0.0625(2\pi\alpha V/NH\nu)$; also $K = 9.45(n^2V/[\lambda + {}^5/_2RT(1 + \beta)])e^{(-\phi/RT)}$, which shows the variation of K with temp. (n_f = the degrees of freedom of rotation and vibration of the mols.). A. W. Contieri

3—SUBATOMIC PHENOMENA AND RADIOCHEMISTRY

A. B. F. DUNCAN

Classical theory of electrons. H. J. Bhabha. *Proc. Indian Acad. Sci.* **10A**, 324–32(1939).—Math. B. shows that when a point charge is present in an electromagnetic field the conservation of energy and momentum does not in general lead to conservation of angular momentum for the system as a whole, and if it is demanded that the equations of motion of a point charge do not contain higher derivs. of the acceleration than the first, then the set of equations possible, consistent with the conservation laws, is unique, and the only possible equations are those originally derived by Lorentz. F. Gonet

The development of the quantum mechanical dispersion theory according to a procedure suggested by M. von Laue. G. Moliere. *Ann. Physik* **36**, 265–74(1939).—A theoretical discussion of the quantum mech. dispersion theory of radiation in which is shown that the ordinary degree of approximation (corresponding to the Kramers-Heisenberg formula, cf. *C. A.* **19**, 3222) is insufficient for optical frequencies. H. C. Thomas

Dielectric constant of space containing electrons. S. R. Khastgir and K. Sirajuddin. *Phil. Mag.* **28**, 532–43(1939); cf. *C. A.* **31**, 5260[8].—The effective dielec. const. in the space between the anode and grid of a screen-grid tube was measured. With increasing wave length the dielec. const. decreases to a min., increases to a max. and then decreases again. The wave length for which the dielec. const. is a max. is greater the smaller the electron concn. An explanation of the observations is given. E. J. Rosenbaum

The role of electrons in certain physicochemical phe-

nomena. N. Vasilesco-Karpen. *Bull. sect. sci. acad. roumaine* 22, 117–29(1939).—Theoretical discussion of electrode potentials based upon the assumption that there is an exchange of electrons as well as ions when a metal is introduced into a soln. of its ions. A. A. Vernon

Electron energy levels of sodium chloride. S. R. Tibbs. *Trans. Faraday Soc.* 35, 1471–84(1939).—Theoretical. The band width of the lowest conduction levels for the (100) direction in NaCl is calcd. Comparison of this breadth (5.45 e. v.) with the corresponding results for free electrons shows that the conduction electrons have an effective mass of the order of magnitude of that of a free electron. Lattice-point wave functions are ascribed to an electron at a vacant, neg. ion and the energy levels deduced therefrom agree with data on *F*-centers. Victor R. Deitz

The probability of reversal of electron spin in collisions in nitric oxide gas. H. O. Kneser. *Physik. Z.* 40, 681(1939).—Preliminary note. Sound measurements at room temp. show no effect of relaxation on absorption. The sp. heat calcd. from the velocity of sound agrees with static measurements. It is concluded that inversion of spin by collision occurs in a relatively short time ($< 10^{-6}$ sec. at 1 atm.). J. B. Austin

Experimental refutation of the statistical concept of the Bohr model of the atom. J. Stark. *Physik. Z.* 40, 590–1(1939).—It is claimed that expts. by Gebauer and v. Traubenberg (*Naturwissenschaften* 18, 417(1930)) and Stark and Patschl (*C. A.* 32, 2023[2]) on H-canal rays disprove the Born-Jordan-Sommerfield concept of the meaning of ψ in the Schroedinger equation. J. B. A.

The separation of the energy steps in atomic nuclei. Paul O. Müller. *Physik. Z.* 40, 615–17(1939).—Taking the nucleus as a sphere of incompressible fluid, the characteristic frequencies of surface and volume waves are calcd. From these can be calcd. energy levels that agree with expt. J. B. Austin

The stability of an elongated-drop model of the nucleus. G. C. Wick. *Nuovo cimento* 16, 229–41(1939).—Math. A study of a drop with a configuration other than spherical leads to the conclusion that it would be unstable. J. B. Austin

A struggle for accuracy. The historical development of the accuracy of the determination of lattice constants with special regard to the asymmetric method. M. Straumanis. *Oesterr. Chem.-Ztg.* 43, 1–14(1940).—58 references. F. C. Nachod

Rectification in discharge tubes. V. T. Chiplonkar. *Proc. Indian Acad. Sci.* 10A, 381–7(1939).—The rectification in discharge tubes was measured in 2 pressure ranges (500 to 20 × 10^{-4} and 0 to 1.8 cm. Hg) for air (i. e., a mixt. of O and N), O and N in differently designed tubes, to try to find a tube without rectification. Rectification was found to be present in all cases and all conditions, though its direction and magnitude vary within wide limits. Frank Gonet

Discharge in tubes in a high vacuum at impulse voltages up to 2.5 million volts. I. A. S. Zingerman and M. I. Korsunskiĭ. *J. Tech. Phys.* (U. S. S. R.) 9, 1345–56 (1939).—Cathodic oscillograms show that the lag of discharge behind the voltage diminishes when the voltage (50–2500 kv.), the gas pressure (10^{-6} to 10^{-2} mm. Hg), and the length of the tube (40–500 cm.) increase. II. A. S. Zingerman. *J. Tech. Phys.* (U. S. S. R.) 9, 1357–63(1939).—At a given voltage the ionization of the gas begins when the product of gas pressure by length of tube has a const. value. The breakdown consists of sep. stages lasting 10^{-6} to 10^{-7} sec. The resistance of the tube decreases from 10^{8} ohms at the start to 100 ohms at the end of the discharge. The yield of electrons increases with voltage. The state and material of the cathode affect the ionization but are without influence on the breakdown. J. J. Bikerman

Recoil of metastable atoms and decreased breakdown of inert gases. W. Rogowski. *Naturwissenschaften* 27, 755–6(1939).—Collision of metastable atoms can liberate electrons. By assuming that these electrons are the initial electrons of spatial recoil and assuming a growth of electron shower by Townsend rule it is found possible to explain the breakdown laws of R., Fucks and Wallraff (*Arch. Elektrotech.* 29, 326(1935); *C. A.* 30, 8008[3]) with quadratic self-excitation characteristics. Owing to diffusion there also is a surface recoil effect of metastable atoms, liberating electrons from the cathode. For Ne in the neighborhood of the breakdown min. this recoil effect is relatively important. B. J. C. van der Hoeven

A new use of Fourier analysis of electron-diffraction patterns. P. Debye. *Physik. Z.* 40, 573–7(1939).—A comparison is made of the treatments of Pauling and Brockway (*C. A.* 30, 1649[4]) and of Roualt (*C. A.* 33, 4863[7]), particularly with respect to the convergence of each method. There should be no difficulty due to convergence in the former (radial distribution) method, while the latter may be subject to the practical difficulty that the desired value of the at. distances is not sufficiently clear in the density curve. J. B. Austin

Optical demonstration of electron diffraction. Jean J. Trillat. *J. phys. radium* 10, 465–9(1939); cf. *C. A.* 26, 1855; 33, 2796[8].—The interpretation of the previously described diagrams is confirmed and clarified by use of the reciprocal lattice model of Burgers and van Amstel (*C. A.* 31, 1691[8]). A. O. Allen

Electronic diffraction with small voltages. Jean J. Trillat. *Compt. rend.* 209, 201–5(1939).—The difficulty of obtaining electronic diffraction diagrams at low voltages is due to the difficulty of obtaining a sufficiently thin film, an adequate vacuum, and suitably sensitive plates. The last difficulty can be overcome by sensitization with Na salicylate (cf. Thorvert, *C. A.* 27, 5662). Other modifications in the process are also described which enable good results to be obtained with voltages of 3000 and less. C. A. Silberrad

Secondary electron emission and charging-up phenomena in insulators. H. Hintenberger. *Z. Physik* 114, 98–109(1939).—The rate of charging-up was measured when surfaces of mica, electrolytic and cryst. Al_2O_3, or single crystals of NaCl were bombarded with electrons of various velocities. The yield of sec. electrons depends on the state of charge of the insulator. The surface is charged either pos. or neg., depending on the velocity of the incident electrons, while under it there is a neg. space-charge. E. J. Rosenbaum

Emission of composite cathodes subject to simultaneous bombardment with electrons and irradiation. P. Borzyak. *J. Tech. Phys.* (U. S. S. R.) 9, 1380–92(1939).—B. could not reproduce the "Shmakov effect," i. e., a lowering of the secondary emission by illumination of Cs_2O cathodes. Neg. results were also obtained with Sb-Cs cathodes. Cs_2O cathodes do not show the Dember effect, i. e., an increase of the electron emission over the additive value at a simultaneous illumination and bombardment. This indicates the inadequacy of the usual interpretation of the Dember effect. This effect may take place when the elec. cond. of the surface layer is considerably raised by illumination; and an opposite effect might be observed when the cond. of the surface layer is insufficient to let pass the sum of the electrons produced by electrons and light. J. J. Bikerman

The behavior of willemite under electron bombardment. E. R. Piore and G. A. Morton. *J. Applied Phys.* 11, 153–7(1940).—Under scanning conditions in a specially designed tube a willemite screen not only deviates from the potential of the accelerating electrode, but also shows potential variations on the surface, which are functions of scanning frequency and current d. and may amount to several thousand v. The dependence of light intensity on voltage can be represented by a power law. S. L. G.

Existence and characteristics of absorbable ionizing radiations emitted by ordinary metals. J. A. Reboul. *J. phys. radium* 10, 470–6(1939); cf. *C. A.* 33, 5738[9]. A. O. Allen

Nature of the particles emitted by sodium chloride irradiated by electrons. M. M. Vudynskiĭ. *J. Tech. Phys.* (U. S. S. R.) 9, 1377–9(1939).—NaCl bombarded by electrons having the energy of 600 e. v. emits only electrons. J. J. Bikerman

Quantum yield of antimony-cesium [photo-] cathodes. S. Yu. Luk'yanov. *J. Tech. Phys.* (U. S. S. R.) 9, 1175–9(1939).—From the relative spectral sensitivity i and the abs. integral sensitivity I the yield was calcd.; it was 0.3 electron per quantum, i. e., higher than any other yield recorded. i had a max. at 420 mμ. I was 40–50 microamp./lumen, when the temp. of the irradiation was 2350° abs. J. J. Bikerman 1

The antimony-cesium photocathode. S. S. Prilezhaev. *J. Tech. Phys.* (U. S. S. R.) 9, 1439–54(1939).—The cell contg. an Sb-Cs cathode was connected with a side tube contg. Cs. The side tube was kept at a temp. t_1, to maintain a definite vapor pressure of Cs in the cell; and the cathode was heated to a temp. t_2, to change the amt. of Cs adsorbed. The "adsorption equilibrium" was reached in a few hrs. The equil. value of the total photosensitivity at a const. t_1 rose with increasing t_2 to a max. and then fell; when t_1 increased from 20 to 186° the temp. of the max. was shifted from 140 to 260°. When the sensitivity i increased, the work function φ diminished according to an equation $\log i = B_1 - B_2\varphi$ (B_1 and B_2 being const.); in the max. of sensitivity φ was 1.30 e. v. The spectral sensitivity always had a max. at 4300 A. and a trace of a relative max. at 5300 A. The surface of Cs-Sb cathodes has a high elec. resistance which is lowered by an increase of temp. This and the gradual increase of the thermionic emission with increasing potential show that Sb-Cs cathodes are nonmetallic. 2
J. J. Bikerman

Gas-filled photocell with magnetic deflection. L. Goncharskiĭ. *J. Tech. Phys.* (U. S. S. R.) 9, 1455–6 (1939).—Ions produced by photoelectrons are deflected by magnetic field and do not reach the photocathode. 3
J. J. Bikerman

Theory of the electrostatic β-particle energy spectrograph. II. F. T. Rogers, Jr. *Rev. Sci. Instruments* 11, 19–22(1940). E. H.

The design of a magnetic β-ray spectrometer. J. L. Lawson and A. W. Tyler. *Rev. Sci. Instruments* 11, 6–18(1940). E. H.

A cloud chamber for lecture experiments. R. Hilsch. *Physik. Z.* 40, 954–5(1939).—The app. permits projection of α-ray tracks. J. B. Austin

Arc-welded atom smasher. Charles H. Jennings. *Welding Engr.* 24, No. 12, 17–19(1939).—Design details and field erection are discussed. A. N. Hird

New investigation of the multiple decomposition of atomic nuclei by cosmic rays. Georg Stetter and Hertha Wambacher. *Physik. Z.* 40, 702–6(1939); cf. *C. A.* 33, 2798⁴.—Tests at different altitudes show that the no. of stars per day per sq. cm. and the mean energy per star increase with height. The no. of particles of low energy is greater at the lower altitudes. The energy ranges from 35 to 370 m. e. v. with a max. at about 50. The angular distribution of the star particles to the vertical is detd. and discussed. J. B. Austin 4

The absorption of cosmic rays in the atmosphere and mesons. Werner Kolhörster and Ilse Matthes. *Physik. Z.* 40, 617–19(1939).—The height at which mesons are formed is calcd. as 7.2 km. With this value and data on atm. absorption coeffs. the mean free path is 5.75 ± 0.19 km., which is approx. const. in the range of height 2.6 to 6.2 km. Below 2 km. the coeff. falls off; this can be explained by assuming the formation of a new secondary radiation, possibly slow mesons. J. B. Austin 5

Neutrons of cosmic ultraradiation. G. Cocconi and V. Tongiorgi. *Naturwissenschaften* 27, 740–1(1939).—A filter paper contg. Rd-Mn of 2.5-hr. half period was wrapped around an Al counter tube 0.15 mm. thick; control tests were made with Po + Be. Neg. results as to cosmic neutrons were obtained at altitudes of 120, 2000 and 3500 m. This work does not contradict the results of Montgomery (*C. A.* 33, 6701⁸), which are of a lower order of frequency than here measured. Results of Halban and Kowarski (*C. A.* 32, 3253⁸) disagree with the authors' results. B. J. C. van der Hoeven 6

Energy distribution and excitation function of neutrons from the transformation of lithium by α-rays. O. Haxel and E. Stuhlinger. *Z. Physik* 114, 178–84(1939).—The slow neutrons produced by bombarding Li^7 with α-particles were studied as a function of α-particle energy with counters lined with B. Energy levels of B^{10} were found at 0.77, 1.32, and 2.09 m. e. v. E. J. Rosenbaum 7

Neutron spectra of the elements boron and beryllium on bombardment with α-rays. E. Stuhlinger. *Z. Physik* 114, 185–96(1939); cf. preceding abstr.—The yields of slow neutrons from B^{11} and Be^9 bombarded by α-particles were studied by a method previously described. Energy levels of the N^{14} nucleus were found at 4.0, 4.75, 5.47, 6.12, and 6.55 m. e. v. For C^{13} the levels are at 9.2, 10.0, and 10.5 m. e. v. Resonance levels of N^{15} were located at 14.64, 14.88, 15.07, 15.23, 15.42, 15.63, 15.79, 15.94, 16.11, 16.24, 16.42, 16.54, 16.63, 16.74, 16.86, 16.99, 17.09, 17.27, and 17.45 m. e. v. The corresponding values for C^{13} are 11.5, 12.3, 12.9, and 13.6 m. e. v. 8
E. J. Rosenbaum

Nuclear disintegrations. Enrico Fermi. *Elec. Eng.* 59, 57–8(1940).—The fission of U in which the U nucleus splits into 2 fragments of comparable size, achieved by the bombardment of U with neutrons, has stimulated great activity in research and may lead to further results of far-reaching importance. C. G. F. 9

The chemical elements and naturally occurring atoms from the viewpoint of isotopes and nuclear investigations. O. Hahn, S. Flügge and J. Mattauch. *Physik. Z.* 41, 1–14(1940).—A review covering the literature from the end of 1937 to the end of 1939. A table shows the wt., nuclear constitution, frequency of occurrence, packing fraction and mass defect for the isotopes of all the elements. Fifty-five references. J. B. Austin 10

The interaction of fast neutrons with uranium nuclei. La. Goldstein, A. Rogozinski and R. J. Walen. *J. phys. radium* 10, 477–86(1939); cf. *C. A.* 33, 8108¹. A. O. Allen 11

Nuclear fission of uranium irradiated with neutrons. Willibald Jentsche and Friedrich Prankl. *Physik. Z.* 40, 706–13(1939).—The energy distribution of the fragments is given. Through exact measurements of the range, the ionization curve for the particles of highest energy is obtained. The particles fall into 2 groups whose origin is discussed in terms of nuclear structure. The energy spectrum for slow and fast neutrons is given. *Th* also shows 2 groups. J. B. Austin 12

The bursting of uranium and thorium nuclei into light atoms. Otto Hahn and Fritz Strassmann. *Physik. Z.* 40, 673–80(1939).—A review of recent work by the authors (*C. A.* 33, 474⁵, 3684⁶, 4511⁵, 8107⁷, 9121⁵). J. B. A. 13

The β-γ coupling of radioactive $_{33}As^{76}$. N. K. Saha. *Naturwissenschaften* 27, 786(1939).—The work of Harteck, *et al.* (*C. A.* 32, 6543²) and of Norling (*C. A.* 33, 3255⁵) on the multiplicity of the β-spectrum of As^{76} can be explained on the basis of the Fermi theory of β disintegration (cf. Bethe, *et al.*, *C. A.* 33, 3678⁷). The As^{76} β-spectrum is a superimposition of 3 elementary spectra with upper limits at 0.8, 1.7 and 2.5 m. e. v. This indicates 2 possible states of excitation of the $_{34}Se^{76}$ nucleus, one having a γ quantum of 1.7 m. e. v. coupled with the 0.8-m. e. v. β spectrum, one having a weak 0.8-m. e. v. γ quantum coupled with a 1.7-m. e. v. β spectrum. More recent work of Harteck (*C. A.* 34, 23⁴) confirms this view. B. J. C. van der Hoeven 14

Concentration of N^{15} by the separating-tube process of Clusius and Dickel. R. Fleischmann. *Physik. Z.* 41, 14–18(1940); cf. Clusius and Dickel, *C. A.* 33, 474⁸.—With 2 tubes 12 m. long and 9 and 11 mm. in diam. 770 cc. gas with 9.2% $N^{14}N^{15}$ was obtained in 6 weeks. From this concentrate 110 cc. contg. 18% $N^{14}N^{15}$ was obtained in 2.5 weeks. J. B. Austin 15

The "chief" and "auxiliary" valencies in complex compounds and mobility of the coördinated particles. A. Polesitskiĭ. *Compt. rend. acad. sci. U. R. S. S.* 24, 540–1 (1939) (in English).—The equivalence of the 4 I atoms in K_2HgI_4 was shown by the method of radioactive indicators. EtI irradiated by slow neutrons was extd. with dil. KI soln., practically all of the radioactive I passing into the aq. layer. In the reaction $HgI_2 + 2KI \rightarrow K_2HgI_4$, first 16

radioactive KI was used, then radioactive HgI_2. By conversion into $Ag_2HgI_4 \rightarrow 2AgI + HgI_2$ and extn. of the HgI_2 with KI soln. and repptn. as Ag_2HgI_4, both AgI and final Ag_2HgI_4 ppts. were measured on the Geiger-Müller counter and both ppts. were always found to be radioactive. When radioactive AgI was boiled with an equiv. amt. of aq. KI, the former lost half of its radioactivity. There was also interchange of Br between AgBr and KBr in soln. No exchange of I atoms occurred on 3 hrs. boiling of IO_3^- ion with KI soln., or of Br atoms on 8 days boiling of BrO_3^- ion with KBr (mentioned as Br in original paper). George Ayers

Absolute intensities of the β-lines of Th B + C + C″ and the internal conversion coefficient of γ-rays. A. Flammersfeld. *Z. Physik* **114**, 227–44(1939).—A magnetic spectrograph with a Geiger counter was used to obtain the β-spectrum of Th B + C + C″ down to very small energies. The abs. intensities of 29 lines were detd. With the very pure samples used, part of the Th C″ was lost by recoil. This was prevented by covering the source with a thin lacquer film. In the energy range 7–12 e. kv. 4 new lines were found. The internal conversion coeffs. were detd. for γ-rays of energy 40, 237.9, and 1620 e. kv. The first of these agrees well with theoretical values for a quadripole transition, but the others are larger. E. J. Rosenbaum

Method of studying the radioactivity of rocks. Edmond Rothé and Mme. A. Hée. *Compt. rend.* **210**, 30–2 (1940).—The method, termed that of "layers of varying thickness," consists in detg. the radioactivity of varying thicknesses of finely powd. rock, obtained by placing in minute trays all of the same diam. but of varying depth amts. of 0.5, 5, 18 and 30 g. of the powder and plotting the measured activity against the thickness. The resultant curves are compared with similar curves given by similarly prepd. powders of (I) a neutral salt contg. 3.77×10^{-5} g. $Th(NO_3)_4$, and (II) $BaCl_2$ contg. 52.2×10^{-12} g. $RaCl_2$. With I the curve is approx. a straight line; with II the curve ends in a horizontal portion indicating that above a certain thickness the radioactivity depends only on the surface portion of the sample. Comparison with these standard curves of those given by the powd. rocks (15 examples given) gives an approx. indication of the amts. of Th and Ra present. C. A. Silberrad

Detection of radioactivity in works of art. Robley D. Evans, Marie Farnsworth, Sanborn C. Brown and Geo. L. Stout. *Tech. Studies Field Fine Arts* **8**, 98–108(1939). —On the assumption that the radioactivity (α-rays) of lead-bearing pigments might throw light on the age of paintings and help to detect forgeries, an app. was devised, allowing the registration of such rays from paintings enclosed in a box. Unfortunately, the results are not conclusive, for a highly radioactive lead paint is not necessarily modern; its radioactivity may be due to contamination. Conversely, an inactive lead paint is not necessarily old; it may come from a somewhat unusual source. A. H. Krappe

Effect of chemical combination on x-ray emission spectra. An experimental study of the $K\alpha_{1,2}$-doublet of the elements $_{11}Na$-$_{16}S$. Nils G. Johnson. Separate, *A.-B. Ph. Lindstedts Univ.-Bokhandel, Lund* **1939**, 72 pp.—Secondary fluorescent x-rays and a spectrograph with a concave grating were used. The compds. studied were halides, oxides, hydroxides, silicates, phosphates, sulfides, sulfates, chlorates, nitrides, phosphides, carbides and alloys. The doublet shifts toward shorter wave lengths for cations, and toward longer wave lengths for anions. For the same emitting cation the shift increases with at. no. of disturbing anions, and the increase is greater for emitting elements of a high valency than for those of a low valency. S. L. Gerhard

Cathode-ray excitation of the *K* β-spectrum of sulfur. The influence of the anticathode material on the line structure. Osvald Lundquist. *Kgl. Fysiograf. Sällskap. Lund, Handl.* **48**, No. 7, 1–20(1937)(in German); cf. *C. A.* **24**, 2948.—Spectra were detd. for 19 metallic sulfides, 4 sulfites and 24 sulfates, with anticathodes of Al, Fe, Co, Ni, Cu, Zn and Ag. The quant. data calculated and discussed. 10 references. W. C. Tobie

The M_1 and M_2 x-ray absorption edges of lead. J. W. McGrath. *Phys. Rev.* **56**, 765–7, 1068(1939).—The M_1 and M_2 absorption edges of lead were measured and found to occur at 3.219 ± 0.005 A. and 3.469 ± 0.005 A. resp. Methods of computing edge energies are discussed and it is noted that many *M* edges show discrepancies between observed and calcd. values. The proposed explanation and meaning of these discrepancies are discussed with particular reference to lead. J. T. B., Jr.

Theory of x-ray scattering by groups of particles. R. Hosemann. *Z. Physik* **113**, 751–68(1939).—The intensity distribution in the central spot does not depend on whether the individual scattering particles are cryst. or not, but it does depend on whether the distances between scattering centers occur with the same frequency. A method is given for obtaining the mass frequency distribution from measurements on the central spot. E. J. R.

New x-ray method for the determination of the submicroscopic structure of materials. R. Hosemann. *Z. Physik* **114**, 133–69(1939); cf. preceding abstr.—Exptl. details are given for obtaining a narrow, fan-like beam of x-rays suitable for studying the central spot in diffraction patterns. The quant. evaluation of the photographs is given in terms of the theory previously published. The method is applied to the structure of hentriacontane and of different samples of triacetylcellulose and ramie fiber. The crystallites in paraffin are very thin plates of more than 400-A. height and great width. All the cellulose fibers show similar patterns when they are oriented in the plane of the x-ray beam. This indicates that sections across the fiber direction are similar. For the different fibers the distributions of micelle lengths differ with respect to the lengths which are most probable. A brief review of the various cellulose models is given and the extent to which the theories are consistent with the results reported here is discussed. E. J. Rosenbaum

Atmospheric absorption. III. Mme. A. Vassy and E. Vassy. *J. phys. radium* **10**, 459–64(1939); cf. *C. A.* **34**, 939[2].—Further discussion of the previously described observations shows that by adding terms due to scattering by aerosols, the entire atm. light absorption can be accounted for. A. O. Allen

The fine structure of hydrogen lines. J. Stark. *Physik. Z.* **40**, 591–2(1939).—By analogy between the spectra of H and the alkalies it is to be expected that each doublet component of the H lines should consist of 3 components, a line of the principal series and 2 secondary lines. The data of Heyden (*C. A.* **31**, 8359[2]) confirm this conclusion. J. B. Austin

Influence of the fine structure on the Stark effect of ionized helium. H. Kubota. *Bull. Inst. Phys. Chem. Research* (Tokyo) **18**, 9–14(1939); cf. *C. A.* **33**, 6152[3].—A comparison between observed and calcd. values. B. C. P. A.

The energy exchange between translation and rotation through collisions. H. Haber. *Physik. Z.* **40**, 541–51 (1939).—The formation of AlH at the cathode in a discharge tube contg. an inert gas and H with Al electrodes is studied by observing the band spectrum emitted at the cathode. In the energy exchange between translation and rotation the result is detd. only by the energy of the colliding particles. J. B. Austin

Equilibrium between phosphorus paranitride $(PN)_n$ and PN deduced from band spectra. Henri Moureu, Boris Rosen and Georges Wetroff. *Compt. rend.* **209**, 207–9(1939); cf. *C. A.* **33**, 4934.—Examn. of the absorption spectrum shows that $(PN)_n$ when heated at 450° emits vapors of PN, the intensity of the spectrum increases as heating increases, but soon begins to indicate presence of P vapor owing to dissocn. of PN, which at 800° is practically complete. C. A. Silberrad

Ultraviolet absorption spectrum of nitrous oxide at +20° and −90°. Jacques Nicolle and Boris Vodar. *Compt. rend.* **210**, 142–4(1940).—Examn. of the ultraviolet absorption spectrum of N_2O at pressures of 100–760 mm., in thicknesses of 70–574 cm., at 20° and −90°

Quantum ... that the absorption is unaffected by pressure; that S is less at −90° than at +20°; that the ratio of mol. extinction coeff. at 20° to that at −90° is 2.95; that the origin of absorption at −90° is at 2350 A.; and that the absorption studied is only one of the branches of Duncan's band with center at about 1900 A. Various other inferences are deduced as probable, including confirmation of Plyler and Barker's results (*C. A.* **26**, 917). C. A. Silberrad 1

Ultraviolet spectrophotometry of Zea mays pollen with the quartz microscope. Fred M. Uber. *Am. J. Botany* **26**, 797–807(1939).—The theory of absorption-spectrum measurement with the quartz microscope is discussed and photoelec., Geiger-Mueller counter and photographic methods of ultraviolet spectrophotometry with the microscope are described. Walls of *Zea mays* pollen grains of different genetic constitutions have similar transmission curves having a broad min. about 2900 A., a max. at 2500 A. and some variation among pollen varieties in the region 3200–3600 A. A single wall transmits 15–20% at 2000 A. Contents of pollen grains are characterized by a min. in transmission around 2600 A., a max. at 2500 A. and a low but const. transmission from 3000 A. to 3600 A. An 8-μ layer of pollen transmits 19–23% at 2650 A. Only a limited correlation of corn pollen absorption spectra with chem. constitution is possible at present. Nelson McKaig, Jr. 2

Effect of ions of the lyotropic series on the infrared absorption spectrum of water. A. M. Buswell, R. C. Gore and W. H. Rodebush. *J. Phys. Chem.* **43**, 1181–4 (1939).—In seeking a more satisfactory explanation of the lyotropic series of ions, the effects of these ions on the dispersion medium or solvent are studied. The effects of addns. of ions of various radii and various energies of interaction on the infrared absorption bands of water are studied. It is shown that the effect of the halogen anions upon the mol. absorption coeff. of water is in a lyotropic sequence parallel with the resp. halogen ionic radii. The absorption of a viscous soln. of $CaCl_2$ is compared with that of double-distd. water. Two opposing effects of the dissolving of an ion on the water mols. are postulated. These are a depolymerization of the liquid structure and an electrostatic orientation of water mols. around the dissolved ion. The infrared absorption is detd. with a prism spectrometer. L. Kolodny 3

Investigation of the frequency of the O-H group in binary mixtures by the method of combination dispersion. III. Combination spectra of solutions of methanol in benzene (I), chlorobenzene (II), fluorobenzene (IV), acetone (V), dioxane (VI), ethyl ether (VII), isoamyl ether (VIII), pyridine (IX) and piperidine (X). V. I. Malyshev. *Compt. rend. acad. sci. U. R. S. S.* **24**, 676–9(1939)(in English); cf. *C. A.* **33**, 3692[4].—An investigation of the dispersion spectra of 3.5, 5.0 and 10.0% alc. solns. in I gave a slight widening of the line ν = 3611 cm.$^{-1}$ and the authors conclude that the benzene mols. hinder the assocn. of MeOH more than do CCl_4. Lines for II were found at ν = 3630 cm.$^{-1}$, and bands were found in the 20% soln. The results for IV were analogous to those in II and the authors conclude that replacing Cl by F does not affect the oscillation of O-H in the MeOH mol. Expts. with bromobenzene were unsuccessful because of its intense decompn. by light. In V, a comparatively wide band was found at ν = 3532 cm.$^{-1}$, and the authors conclude that either because of the greater elec. moment or the pressure of an O atom, the oscillation of O-H was disturbed in a different manner from I–IV. Hence VI was used and a band appeared at ν = 3516 cm.$^{-1}$ (being double in the 2.0 and 3.5% solns.), with no bands for assocd. MeOH mols. VII gave a max. at ν = 3516 cm.$^{-1}$, analogously to VI. From expts. with VI, VII, VIII, the authors conclude that the O-atom and not the moment causes the disturbance of the oscillation of the O-H groups in alc. In IX and X, a max. was found at ν = 3406 cm.$^{-1}$ for IX, showing even more disturbance by the N atom than by the O atom. The authors conclude that the solvents can be divided into 2 groups; those with O and N, and those without, where the former cause an intense disturbance, which is attributed to the formation of a H-bond between the OH group of the alc. mol. and the O or N mol. of the solvent. Frank Gonet 4

Infrared transmission of thin films of various organic materials. A. J. Wells. *J. Applied Phys.* **11**, 137–40 (1940).—Measurements were made on cellophane, ethylcellulose, cellulose acetate, Duco household cement, polystyrene, Glyptal, Pliofilm, rubber, Plexiglas, Me methacrylate polymer, XYSG Vinylite and Shawinigan V-15 resin from 400 to 3000 cm.$^{-1}$. Methods for making thin films are described. In general these materials become more transparent in the region from 400 to 900 cm.$^{-1}$, in some instances surpassing KBr. The most transparent materials in this region are Plexiglas, ethylcellulose and Me methacrylate resin. S. L. Gerhard 5

Raman effect in ethane and butane. Sizuo Nakamura and Eizo Kanda. *J. Chem. Soc. Japan* **60**, 1275–8 (1939); cf. *C. A.* **34**, 1563[4].—The Raman spectra of ethane in the liquid state and of butane in the liquid as well as in the solid state have been taken and the geometrical forms of mols. are discussed. Conclusion: The butane mol. has the trans form in the solid state, while in the liquid state it contains another rotational isomer besides the trans form. T. Katsurai 6

Studies of hydrocarbon mixtures by means of the Raman effect. III. Hiroatu Okazaki. *J. Chem. Soc. Japan* **60**, 1269–74(1939); cf. *C. A.* **33**, 9140[1].—The petroleum prepd. by Fischer's method (catalyzer, Fe and Co) was analyzed by means of the Raman effect. It was confirmed that the petroleum consists chiefly of normal paraffins contaminated with olefins and benzene. Normal pentane, hexane and octane from petroleum (Kahlbaum and Frenkel-Landau) were also analyzed and their impurities estd. T. Katsurai 7

Raman spectra of crystalline powders: hydrates. Étienne Canals and Henri Collet. *Compt. rend.* **209**, 212–14(1939); cf. *C. A.* **32**, 6948[3].—The Raman spectra (3200–3800 cm.$^{-1}$) $MgSO_4.n_1H_2O$, $Na_2HPO_4.n_2H_2O$ and $CuSO_4.n_3H_2O$ (n_1 = 7 and 6, n_2 = 12, 7 and 2, n_3 = 5 and 3) are compared, showing differences between salts with the same no. of H_2O mols., and between hydrates of the same salt with different nos. of H_2O mols. C. A. S. 8

The spectral emission of nickel at different temperatures. F. Cennamo. *Nuovo cimento* **16**, 253–60(1939); cf. *C. A.* **33**, 9132[9].—The emission is detd. between 1 μ and 7 μ at temps. above the Curie point. The Wien law is verified in the range 590° to 1145°K. The following relation is derived $\lambda_m T = 0.060\ T^{0.22}$, where λ_m is the wave length of max. emission at temp. T. The reflecting power is calcd. J. B. Austin 9

Birefringence measurements in the far ultraviolet. Roger Servant. *Compt. rend.* **209**, 206–7(1939); cf. *C. A.* **30**, 6642[1].—With S.'s vacuum polarimeter the birefringence of barite and gypsum was detd. at 17° for λλ 2749.2–1693.9 and 2355.5–1726.6, resp., in which intervals the birefrigence increased from 19.82 to 72.15 and from 11.18 to 24.39. C. A. Silberrad 10

The fundamental chemical reactions in the light emission of sulfide phosphors. Rudolf Schenck. *Z. Elektrochem.* **46**, 27–38(1940).—A review. G. G. 11

Binding of excess sodium in sodium chloride crystals with added strontium chloride. H. Pick. *Z. Physik* **114**, 127–32(1939).—The absorption spectra of NaCl crystals with added $SrCl_2$ and colored by excess Na were obtained at room temp. and at −210°, after irradiation with light in the F band and with x-rays. At room temp. the F band and 2 bands belonging to the cation overlap; this gives the unresolved band the appearance of a shift to the red. These bands are resolved at low temps. E. J. Rosenbaum 12

Luminescent materials. IV. Molecular vibration structure of fluorescence spectra of zinc sulfide crystal phosphor. Yasuo Uehara. *J. Chem. Soc. Japan* **60**, 1293–301(1939); cf. *C. A.* **34**, 1565[8].—The fluorescence of the pure zinc sulfide crystal phosphor is attributed to the resonance radiation. A theoretical formula is derived for the temp. dependence of photoconductance of the

zinc sulfide crystal phosphor. It is confirmed that the formula holds for a certain range of temp. T. Katsurai

Method for determining the amounts of light emitted by mixed phosphors with mixed emitters. P. Brauer. *Z. Physik* **114**, 245–50(1939); cf. *C. A.* **34**, 3243.—A device is described for automatically repeating the illumination of a phosphor and its subsequent heating in such a position that the emitted light is collected in a spectrograph. The results on a CaO-Sm,Pr phosphor are given as an example. E. J. Rosenbaum

Infrared luminescence of the rare elements: application to analysis. Marcel Servigne. *Compt. rend.* **209**, 210–12 (1939); cf. *C. A.* **33**, 4773.—The infrared emission spectra of Nd and Pr (oxides) dild. in $CaWO_4$ were detd. as far as λ 12,000 A. This spectrum is specially valuable with Nd, which gives no lines in the near infrared (λ less than 8600). It is apparent when $5/10^6$ Nd is present in the diluent, and is unaffected by the presence of 100 times its amt. of Sm. The method is exemplified by the near infrared spectrum of a sample of scheelite showing traces of Pr, Sm, Eu, Tb, Dy, Er and Gd, while the distant infrared spectrum shows Nd distinctly. C. A. Silberrad

Ultraviolet luminescence of deformed and undeformed sodium chloride crystals. M. L. Kats and R. E. Solomonyk. *Compt. rend. acad. sci. U. R. S. S.* **24**, 683–6 (1939) (in German).—The ultraviolet spectra of deformed and undeformed NaCl crystals were investigated and the authors conclude that there are 3 kinds of centers in the deformed NaCl crystals, where the emission of the short-wave band (2400 A.) can be explained by transitions from a center level to the ground level, the middle band by perturbations of the former through plastic deformation, and the long-wave band by the presence of impurities introduced by chem. transformation during the tempering process. Frank Gonet

Fluorescence of sodium formate in soda solution. Albert Grumbach and René Millet. *Compt. rend.* **210**, 49–50(1940); cf. *C. A.* **28**, 1928.—Neither pure Na formate nor pure NaOH is fluorescent, but if a trace of formate is added to NaOH, fluorescence is developed. The same effect occurs if a drop or so of soln. of the formate is added to one of NaOH (care was taken to ensure exclusion of any CO_2 and complete absence of any org. matter). The intensity varies with the amt. of formate, being a max. for the addn. of 0.36 g. to a soln. contg. 60 g. NaOH in 100 cc. H_2O. C. A. Silberrad

A new luminous material containing bivalent europium, and the color and excitation of fluorite. Karl Przibram. *Mitt. Inst. Radiumforsch. No. 412a; Anz. Akad. Wiss. Wien* **75**, 24–5(1938); *Neues Jahrb. Mineral. Geol.*, Ref. I, **1938**, 567–8.—Addn. of a few percent of Eu oxalate or sulfate to pure $CaCl_2$ and heating to 300–400° gives a mixt. showing the blue fluorescence of $EuCl_2$, the Eu^{+++} being largely reduced to Eu^{++}. By daylight the prepn. has a blue color, similar to that of Weardale fluorite, which is to be ascribed either to the Eu^{++} ion or to partially or wholly reduced Ca. C. A. Silberrad

Fluorescence and pH of solutions of uranine. Augustin Boutaric and Madeleine Roy. *Compt. rend.* **209**, 162–4 (1939); cf. Bouchard, *C. A.* **30**, 3328.—The fluorescent power (φ) of solns. of uranine (0.59/l.) of varying pH is detd. It increases with pH, at first moderately rapidly and then more slowly, approx. doubling for a rise in pH from 4.6 to about 6, trebling at pH 7, and becoming approx. const. at slightly under a quadruple value at pH 8 and above. The effect of addn. of other substances was examd., confirming the inhibitory effect of resorcinol (cf. Perrin, *C. A.* **26**, 3434). In other cases the apparent effect of the addn. is solely due to change in pH. C. A. Silberrad

Chemiluminescence of 3-aminophthalic hydrazide (luminol). E. S. Vasserman. *Compt. rend. acad. sci. U. R. S. S.* **24**, 704–6(1939) (in English).—The action of various catalysts upon the glow of luminol oxidized by H_2O_2 was investigated. Cu excites a strong but very short flash, Fe^{II} and Mn^{II} give a short but weak flash, Ni salts do not react at all. Co^{III} acts very weakly, while Co^{II} gives the strongest and most durable effect (especially at pH 10.6–11.0 and in the presence of a carbonate ion). Frank Gonet

Thermoluminescence. H. Steinmetz. *Mitt. Wien. Ges. No.* 104 in *Mineralog.-Petrog. Mitt.* **50**, 87(1938); *Neues Jahrb. Mineral. Geol.*, Ref. I, **1938**, 539; cf. *C. A.* **31**, 2933.—Methods of measuring thermoluminescence are described, and its connection with fluorescence and mineral coloration is described. C. A. Silberrad
